What's New for developers in Windows 11

Article • 01/28/2025

Following the announcements at Microsoft Build 2024, here are some of the latest highlights for Windows developers:

- Updated recommendations for app development
- New AI and machine learning capabilities supported by Windows
- Enhanced developer tools

Development recommendations

You are strongly encouraged to consider using either the Windows App SDK/WinUI or WPF as your development platform for creating Windows client applications.

Windows App SDK

Expand table

Feature	Description
Windows App SDK	The Windows App SDK is a set of developer components and tools that represent the next evolution in the Windows app development platform. The Windows App SDK provides a unified set of APIs and tools that can be used in a consistent way by any desktop app on Windows 11 (and downlevel to Windows 10, version 1809).
Windows App SDK release notes	Details on the latest stable release of the Windows App SDK, which can be used by apps in production environments and by apps published to the Microsoft Store.
Create a new app with the Windows App SDK	The Windows App SDK includes WinUI 3 project templates that enable you to create apps with an entirely WinUI-based user interface. When you create a project using these templates (see Create your first WinUI 3 project), the entire user interface of your application is implemented using windows, controls, and other UI types provided by WinUI 3.
Use the Windows App SDK in an existing project	If you have an existing project in which you want to use the Windows App SDK, you can install the latest version of the Windows App SDK NuGet package in your project. Unpackaged apps must follow this procedure to use the Windows App SDK, but packaged apps can do this too.

Feature	Description
Download the Windows App SDK	There are several packages and release channels for the Windows App SDK. The Download the Windows App SDK page provides guidance on which ones you need, download links, and installation instructions.

WinUI

Expand table

Feature	Description
WinUI	WinUI is the native UI platform component that ships with the Windows App SDK (completely decoupled from Windows SDKs). The Windows App SDK provides a unified set of APIs and tools that can be used to create production desktop apps that target Windows 10 and later, and can be published to the Microsoft Store.

Windows AI

Expand table

Feature	Description
Windows AI	Enhance your Windows apps with AI through local APIs and Machine Learning models.
Windows Copilot Runtime Overview	Windows Copilot Runtime introduces new ways of interacting with the operating system that utilize AI, such as Phi Silica, the Small Language Model (SLM) created by Microsoft Research that is able to offer many of the same capabilities found in Large Language Models (LLMs), but more compact and efficient so that it can run locally on Windows.

Developer tools

Expand table

Feature	Description
Dev Home Overview	Dev Home was an experimental control center for Windows, but will no longer be supported beginning May 2025. Dev Home provided the ability to monitor projects in your dashboard using customizable widgets, set up your dev environment by downloading apps, packages, or repositories, connect to your

Feature	Description
	developer accounts and tools (such as GitHub), and create a Dev Drive for storage all in one place.
WSL (Windows Subsystem for Linux)	Windows Subsystem for Linux (WSL) is a feature of Windows that allows you to run a Linux environment on your Windows machine, without the need for a separate virtual machine or dual booting.

Samples

The WinUI 3 Gallery on GitHub is updated regularly to showcase the latest additions and improvements to WinUI in the Windows App SDK. The gallery app can also be downloaded from the Microsoft Store.

Overview of framework options

Article • 03/03/2025

This article contains the information you need to get started building apps for Windows.

Windows offers a wide range of languages, frameworks, and tools for building apps, including WinUI, React Native for Desktop, WPF, C++, C#, .NET, and a variety of cross-platform frameworks. Here, we provide information to help you decide which option is best for you.

WinUI

We recommend WinUI and the Windows App SDK to create apps that look great and take advantage of the latest Windows releases. If you're new to Windows development, or starting work on a new Windows app, WinUI provides the resources you need to create great apps for Windows 11.

WinUI is a XAML markup-based user interface layer that contains modern controls and styles for building Windows apps. As the native UI layer for the Windows App SDK, it embodies Fluent Design, giving each Windows app the polished feel that customers expect.

Get started with WinUI

> **Note**
>
> The Windows App SDK is a set of new developer components and tools that represent the latest evolution in the Windows app development platform. The Windows App SDK provides a unified set of APIs and tools that can be used in a consistent way by desktop apps on Windows 11 and downlevel to Windows 10, version 1809.
>
> While WinUI is the native UI layer, you can use the Windows App SDK with WPF, WinForms, or Win32 apps. If you've developed apps for Windows before, but are looking to get started with the Windows App SDK in an existing app, see Framework-specific guides.

React Native for Desktop

React Native is a development platform which allows building cross-platform apps. React Native for Desktop encompasses React Native for Windows and macOS, bringing React Native support to the Windows SDK. React Native for Desktop lets you use JavaScript to build native Windows apps for all devices supported by Windows 10 and Windows 11. This includes PCs, tablets, 2-in-1s, Xbox, Mixed Reality devices, etc.

With React Native for Desktop, you write most or all of your app code in JavaScript - or TypeScript - and the framework produces a native UWP XAML application. If your app needs to call a platform API, you can usually do so through one of the many community modules, or if a module does not yet exist, you can easily write a native module to expose it.

Here are some reasons to choose React Native for Desktop:

- You want to share code across platforms as much as possible, or you have web properties that you want to share code with.
- Improved developer productivity and inner loop, thanks to fast refresh.
- Your app's fundamentals (performance, accessibility, internationalization) are as good as a native UWP app.
- You have experience with and a preference for JavaScript or TypeScript
- You would like to leverage JavaScript-only libraries on npmjs.com, and many native libraries too.
- Your app will use the native controls, visual appearance, animations and colors, and therefore will feel integrated into the design language used in Windows. In addition, React Native for Desktop apps do not have to compromise on the set of APIs they can call, as the framework allows you to call platform APIs as well as write your own view managers and native modules.
- Large and growing community momentum, with lots of community modules.

Get started with React Native for Desktop

For more information about React Native for Desktop, see the following links:

- React Native for Windows repo on GitHub
- React Native for macOS repo on GitHub
- API reference
- React Native for Desktop resources

WPF

WPF is a well-established framework for Windows desktop applications with access to .NET or the .NET Framework. Like WinUI, it also uses XAML markup to separate UI from code. WPF provides a comprehensive set of application development features that include controls, data binding, layout, 2D and 3D graphics, animation, styles, templates, documents, media, text, and typography. WPF is part of .NET, so you can build applications that incorporate other elements of the .NET API.

Additionally, you can now integrate a sandbox environment into your packaged WPF applications, providing an additional layer of security. This enhancement requires little to no change to your code, thanks to the new Win32 App Isolation security feature.

> **Tip**
>
> If you've already invested in WPF, you can continue to use it and take advantage of the modernization options in .NET 9. You can build your apps knowing that Microsoft is continuing to invest in WPF. See the **Windows developer FAQ** for more information.

Get started with WPF

If you have a WPF .NET app, you also have access to modern Windows platform features and APIs provided by the **Windows App SDK**. For more information, see Use the Windows App SDK in a WPF app and Modernize your desktop apps.

> **Tip**
>
> If you need more help deciding which framework is the best choice for your app, see the **Choose the best application framework for a Windows development project** training module.

Other native platform options

Many apps for Windows are written using Win32, Windows Forms, or UWP. Each of these frameworks is supported and will continue to receive bug, reliability, and security fixes, but varying levels of investment for new features and styles. For more information about these app types see the following tabs.

Win32

Win32 desktop apps (also sometimes called *classic desktop apps*) are the original app type for native Windows applications that require direct access to Windows and hardware. This makes Win32 the app type of choice for applications that need the highest level of performance and direct access to system hardware.

Using the Win32 API with C++ makes it possible to achieve the highest levels of performance and efficiency by taking more control of the target platform with un-managed code than is possible on a managed runtime environment like WinRT and .NET. However, exercising such a level of control over your application's execution requires greater care and attention to get right, and trades development productivity for runtime performance.

Here are a few highlights of what the Win32 API and C++ offers to enable you to build high-performance applications.

- Hardware-level optimizations, including tight control over resource allocation, object lifetimes, data layout, alignment, byte packing, and more.
- Access to performance-oriented instruction sets like SSE and AVX through intrinsic functions.
- Efficient, type-safe generic programming by using templates.
- Efficient and safe containers and algorithms.
- DirectX, in particular Direct3D and DirectCompute.
- Use C++/WinRT to create modern desktop Win32 apps with first-class access to Windows Runtime (WinRT) APIs.

Additionally, you can now integrate a sandbox environment into your Win32 applications, providing an additional layer of security. This enhancement requires little to no change to your code, thanks to the new Win32 App Isolation security feature.

Get started with Win32

You also have access to modern Windows platform features and APIs provided by the **Windows App SDK**. For more information, see Use the Windows App SDK in an existing project and Modernize your desktop apps.

Other cross-platform options

If you need your app to be cross-platform, in addition to React Native for Desktop, you should consider .NET MAUI or a Progressive Web App (PWA). There are many other choices available (here's a list of popular options), but these are some good starting points.

.NET MAUI harnesses the power of WinUI on Windows, while also enabling execution on other operating systems. Another cross-platform option, Progressive Web Apps (PWAs), are websites that function like installed, native apps on Windows and other supported platforms, while functioning like regular websites on browsers.

For more information, see the following tabs.

.NET MAUI

.NET Multi-platform App UI (MAUI) is an open-source, cross-platform framework for building Android, iOS, macOS, and Windows applications that leverage the native UI and services of each platform from a single .NET code base. Because .NET MAUI favors platform native experiences, it uses WinUI and the Windows App SDK so apps get the latest user experience on Windows. This gives your apps access to everything you get with WinUI plus the ability to reach to other platforms.

.NET MAUI for Windows is a great choice if:

- You want to share as much .NET code as possible across mobile and desktop applications.
- You want to ship your application beyond Windows to other desktop and mobile targets with native platform experiences.
- You want to use C# and/or XAML for building cross-platform apps.
- You're using Blazor for web development and wish to include all or part of that in a mobile or desktop application.

Get started with .NET MAUI

For more information about .NET MAUI, see the following links:

- .NET MAUI documentation
- .NET MAUI on GitHub
- .NET MAUI Product Roadmap
- Build Windows apps with .NET MAUI
- Resources for learning .NET MAUI
- Video Series - .NET MAUI for Beginners
- Build 2022: Build native apps for any device with .NET and Visual Studio

App development framework feature comparison

There is a wide range of options for developing applications for Windows. The best option for you depends on your application requirements, your existing code, and your familiarity with the technology. The following table lists the most popular app development frameworks available on Windows and the features supported by each framework.

Expand table

Feature	.NET MAUI	Blazor Hybrid	React Native for Desktop	UWP XAML (Windows.UI.Xaml)	Win32 (MFC or ATL)	Windows Forms	WinUI 3	WPF

Next steps

- Use WinUI to start developing apps for Windows

> WinUI is our recommended platform for Windows apps, and these steps will quickly get you started.

- Set up your development environment on Windows

  > Windows isn't just great for developing apps that run on Windows, it's also a powerful environment for developing apps for any platform. Learn more about the tools and options available to maximize your development.

Start developing Windows apps

Article • 03/28/2025

Welcome to Windows app development. This guide will take you through the steps needed to begin creating apps using the latest Windows development frameworks: the Windows App SDK and WinUI. It will also point you to resources that will help you learn more about Windows development. If you are already comfortable developing apps for Windows, but want to know more about the latest tools, please see Develop Windows desktop apps.

> **Tip**
>
> Microsoft Copilot is a great resource if you have questions about getting started writing Windows apps.

1. Enable Developer Mode

Windows has a special mode for developers that adjusts security settings in order to let you run the apps you're working on. You'll need to enable Developer Mode before you can build, deploy, and test your app using Visual Studio.

> **Tip**
>
> If you don't enable it now, you'll be prompted to enable it when you try to build your app in Visual Studio.

To enable Developer Mode:

- Open Windows Settings and navigate to the **System > For developers** page.
- Toggle the Developer Mode switch to **On** and confirm your choice in the confirmation dialog.

For more information about Developer Mode, see Enable your device for development.

2. Install Visual Studio

You'll use Visual Studio, Microsoft's comprehensive integrated development environment (IDE), to create your WinUI app. It's the preferred development tool of many Windows developers and it will help you write, debug, and deploy your apps. The

project templates in Visual Studio will quickly get you started with projects for Windows and many other platforms.

> **Tip**
>
> Before installing these tools, make sure your development computer meets the system requirements for Windows app development.

Use the link below to download and install the latest Visual Studio. The installer will walk you through the steps, but if you find you need detailed instructions, see Install Visual Studio.

Download Visual Studio

The free Visual Studio Community Edition includes everything you need to create your apps. If you're working with a development team or enterprise, you might need Visual Studio Professional or Visual Studio Enterprise. See What is Visual Studio? for more info.

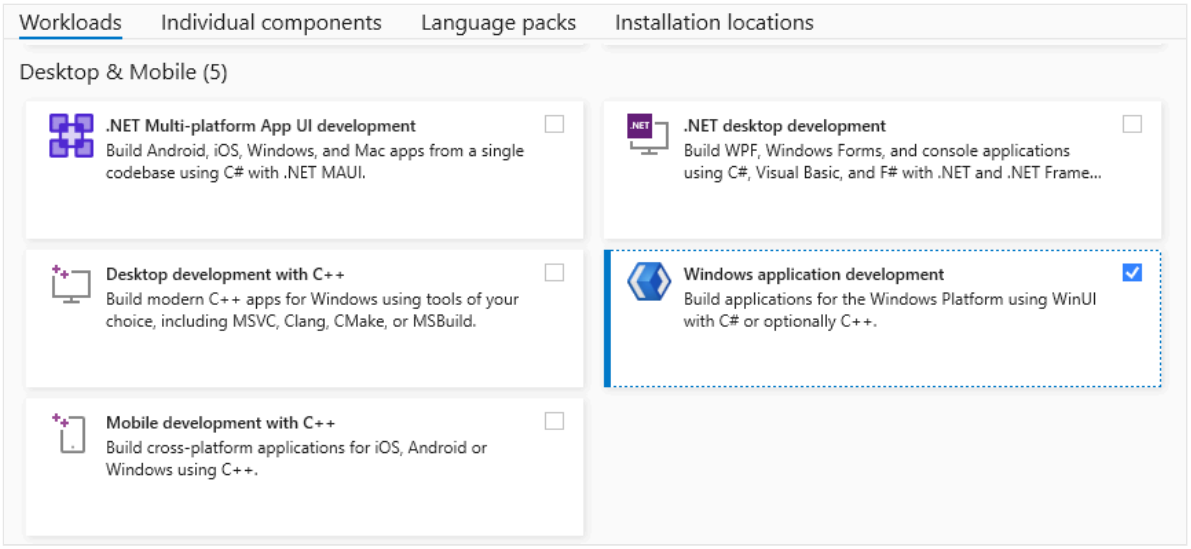
2.2 Required workloads and components

While installing Visual Studio, you need to install the workloads and components required for developing with WinUI and the Windows App SDK. After installation, you can open the Visual Studio Installer app and select **Modify** to add workloads and components.

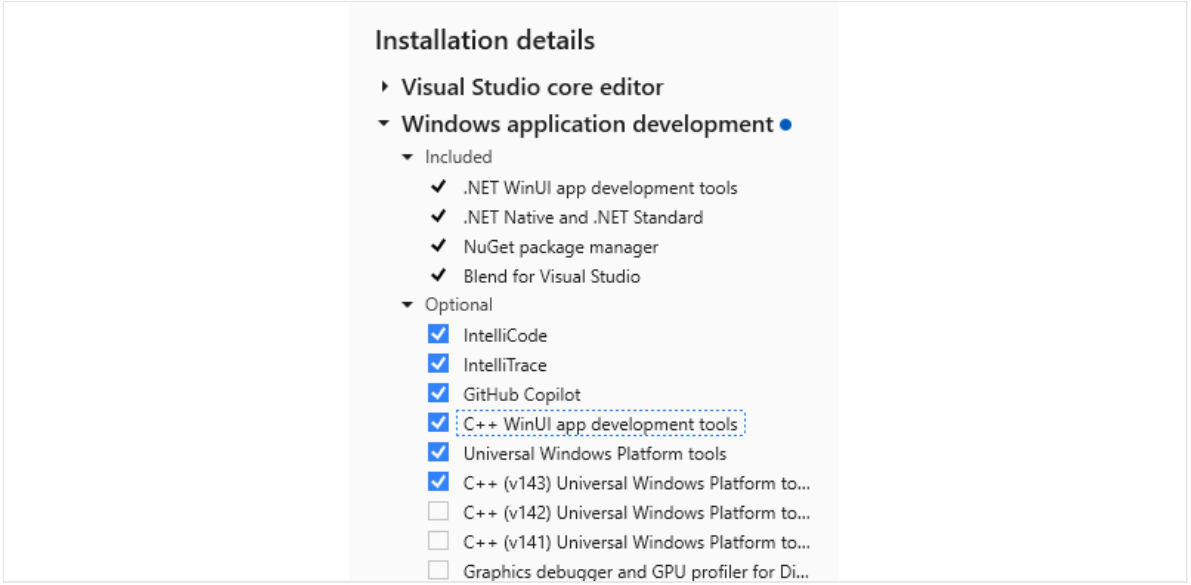
On the **Workloads** tab of the Visual Studio Installer app, select the following workloads and components:

Visual Studio 2022 version 17.10 and later

- For **C#** app development using the Windows App SDK, select **Windows application development**.



- For **C++** app development using the Windows App SDK, select **Windows application development**.
  - Then in the **Installation details** pane, under the **Windows application development** node, select **C++ WinUI app development tools**. (This will also select any additional required components.)

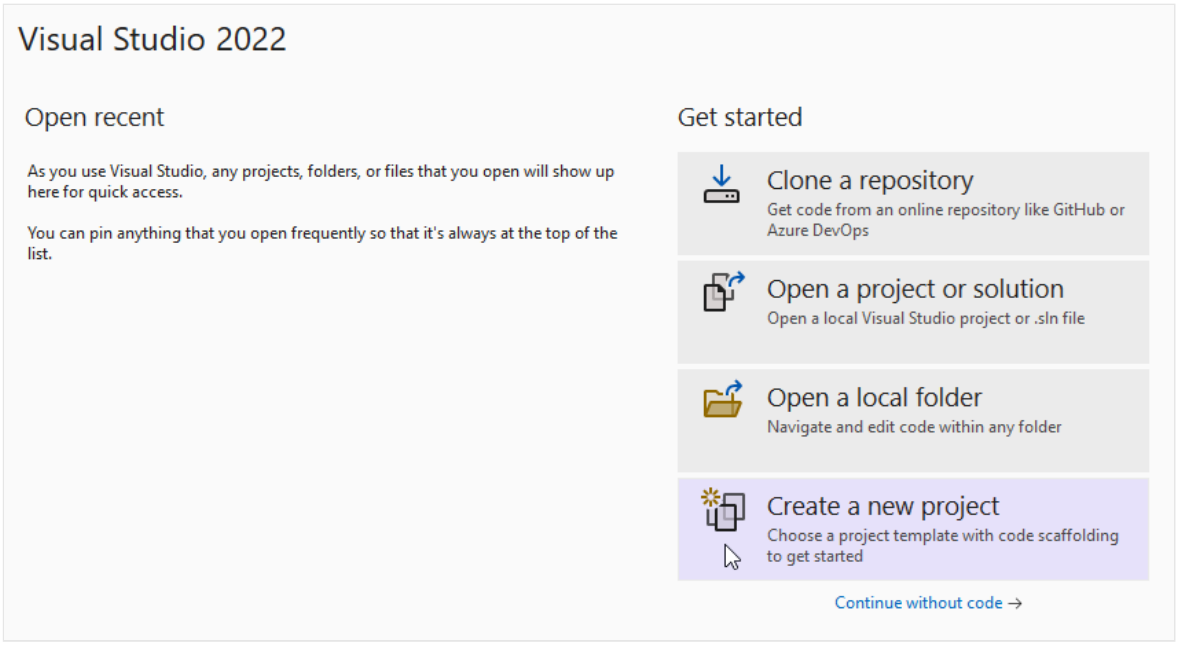


3. Create and launch your first WinUI app

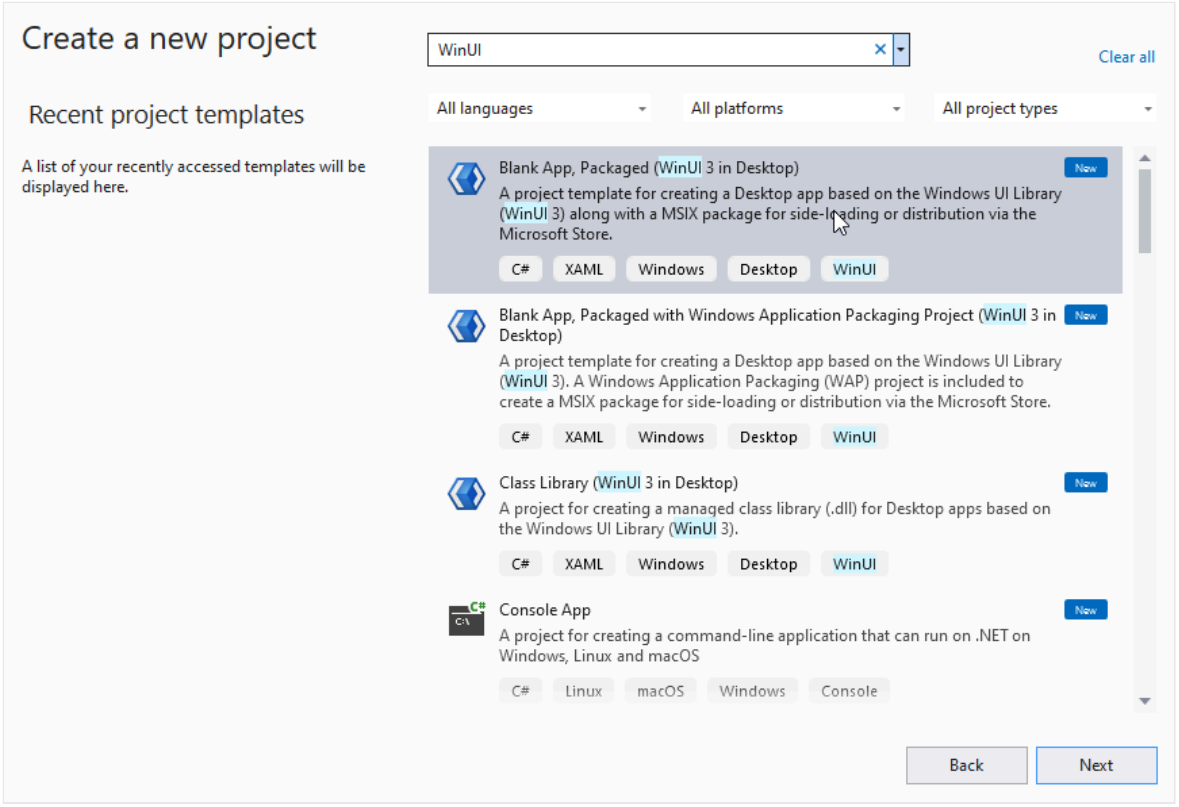
Visual Studio project templates include all the files you need to quickly create your app. In fact, after you create your project from a WinUI app template, you'll already have an app that you can run, and then add your code to.

To create a new project using the WinUI C# Blank App project template:

1. Open Visual Studio and select **Create a new project** from the launch page. (If Visual Studio is already open to the editor, select **File** > **New** > **Project**):

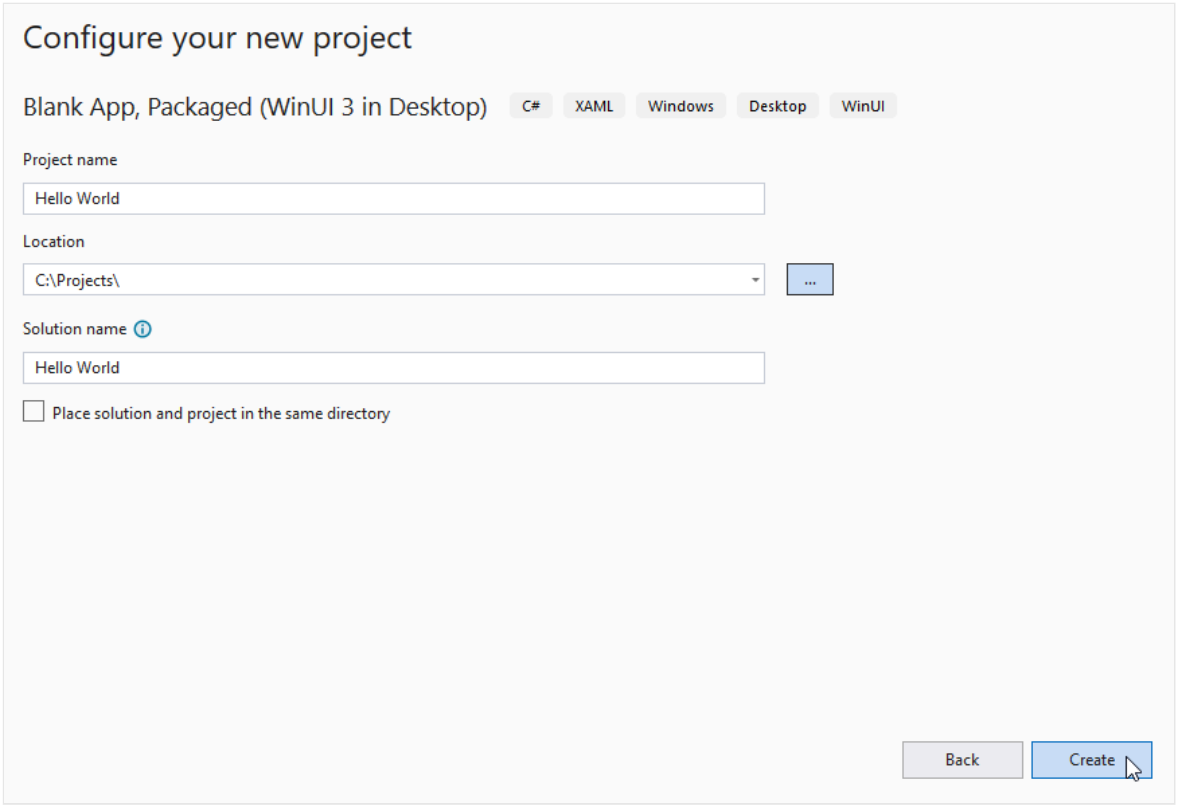


2. Search for `WinUI` and select the `Blank App, Packaged (WinUI 3 in Desktop)` C# project template, then click **Next**:



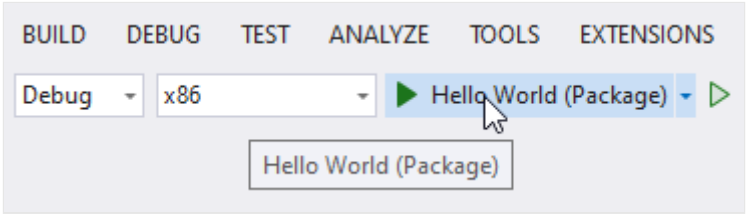
3. Specify a project name, then click **Create**. You can optionally specify a solution name and directory, or leave the defaults. In this image, the `Hello World` project

belongs to a `Hello World` solution, which will live in `C:\Projects\`:

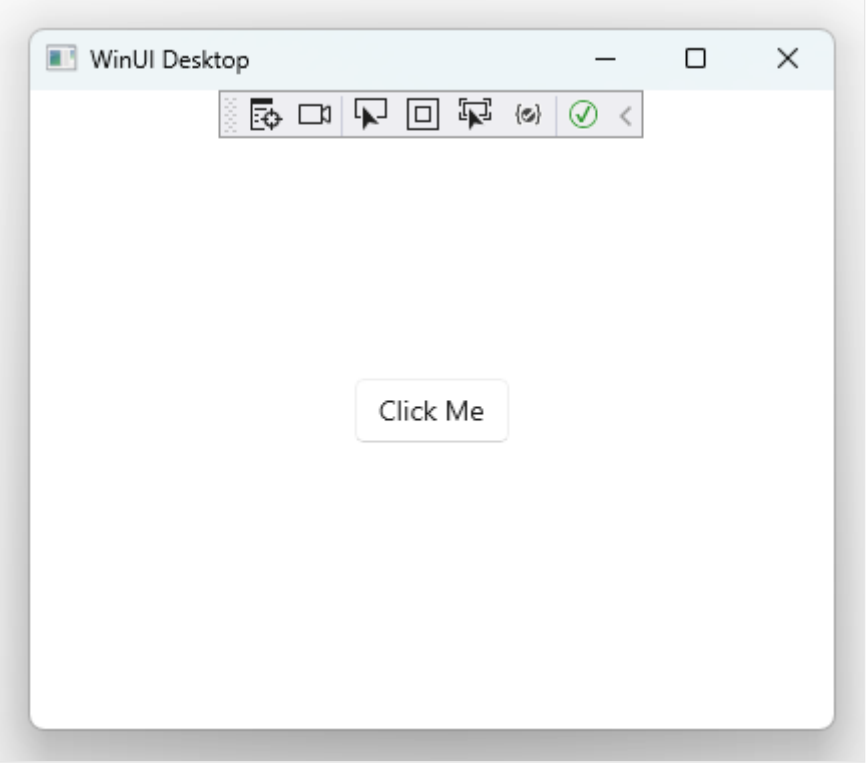


> **Note**
>
> If you want to use this project to build the complete app in the Next steps section, name the project `WinUINotes`.

4. Click the Debug "Start" button to build and run your project:



Your project will build, be deployed to your local machine, and run in debug mode:



5. To stop debugging, close the app window, or click the debug "Stop" button in Visual Studio.

4. Delete sample code

The `MainWindow` class included with the project template includes some sample code that needs to be removed to make room for your content.

1. Double-click `MainWindow.xaml` in **Solution Explorer** to open it. You should see XAML markup for a `StackPanel` control.

2. Delete the XAML for the `StackPanel`. (You'll add your own content in it's place as you create your app.)

   XAML

   ```
   <!-- ↓ Delete this. ↓ -->
   <StackPanel Orientation="Horizontal" HorizontalAlignment="Center"
   VerticalAlignment="Center">
       <Button x:Name="myButton" Click="myButton_Click">Click Me</Button>
   </StackPanel>
   ```

   If you try to run your app now, Visual Studio will throw an error along the lines of `The name 'myButton' does not exist in the current context`. This is because you

deleted the `Button` control named `myButton`, but it's still referenced in the `MainPage.xaml.cs` code-behind file. Delete the reference in the code file, too.

3. Double-click `MainWindow.xaml.cs` in **Solution Explorer** to open it.

4. Delete the `myButton_Click` event handler.

```
C#
```

```
public sealed partial class MainWindow : Window
{
    public MainWindow()
    {
        this.InitializeComponent();
    }

    // ↓ Delete this. ↓
    private void myButton_Click(object sender, RoutedEventArgs e)
    {
        myButton.Content = "Clicked";
    }
    // End delete.
}
```

5. Save the file by pressing `CTRL + SHIFT + S`, clicking the Save All icon in the tool bar, or by selecting the menu **File** > **Save All**.

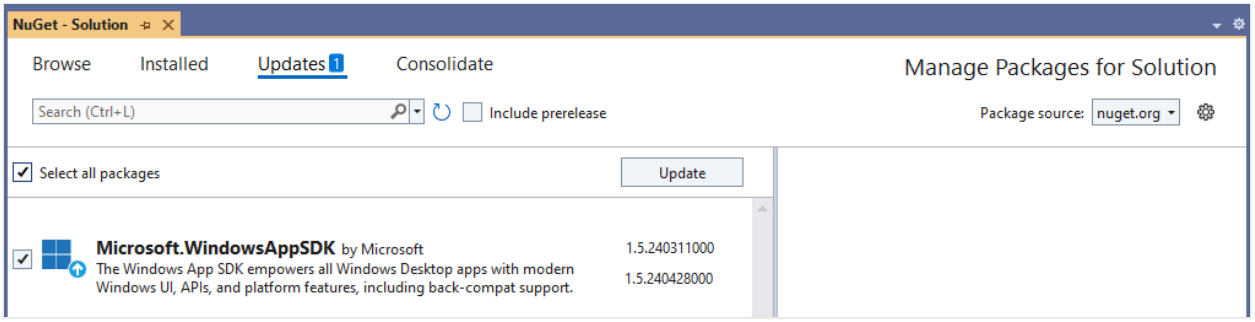
5. Update to the latest WinUI/Windows App SDK

The Windows App SDK (and WinUI, which is part of it) is distributed as a NuGet package. This means updates can be released out-of-sync with Windows and Visual Studio. As a result, the Visual Studio template you used to create your project might not reference the latest Windows App SDK NuGet package. To ensure you have the latest features and fixes, you should update your NuGet packages every time you create a new project in Visual Studio.

To update the Windows App SDK NuGet package for your project:

- In Visual Studio, with your project loaded, select **Tools** > **NuGet Package Manager** > **Manage NuGet Packages for Solution...**.
- If an update is available, it will appear on the Updates page. Check the box next to the listed update. (To include prerelease updates, check the "Include prerelease" option. To learn more about what's included in an update, see the release notes.)

- Click the **Update** button, then click **Apply** in the Preview changes dialog, then accept the license terms to finish installing the update.



Now your project is using the latest WinUI features that are available, and it's ready for you to make it your own.

Next steps

Complete a tutorial to create a note app with WinUI

- To get an idea of what WinUI has to offer, check out the WinUI Gallery app.

  > The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

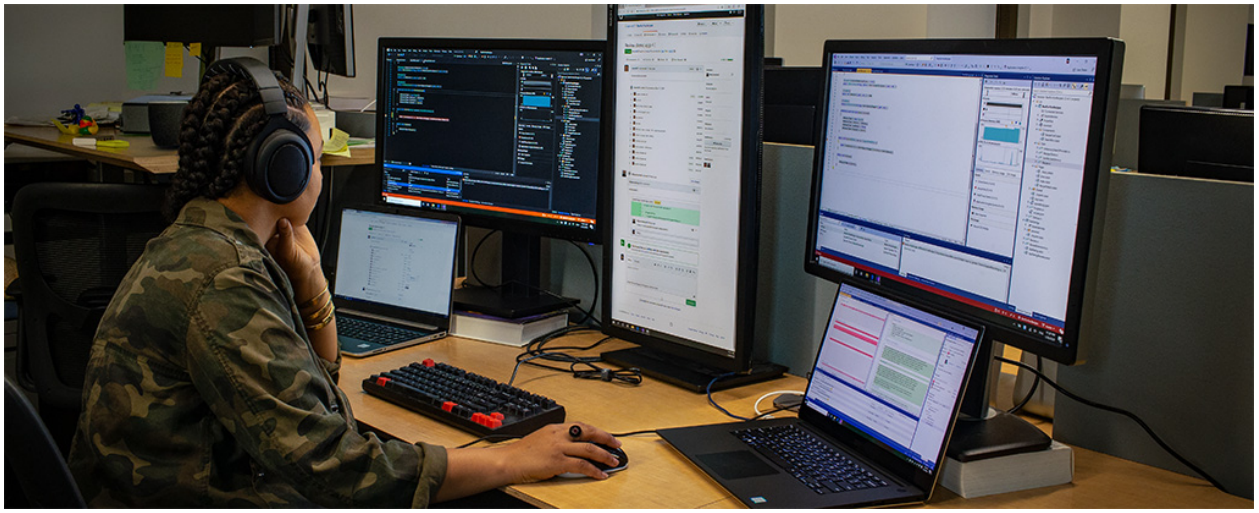
- Find samples and tools to help you develop apps more efficiently.

Samples and resources

Article • 08/19/2024

This page contains links to resources that can make you more efficient as you develop your apps for Windows. It includes sample apps and toolkits; code samples that demonstrate specific tasks, features, and API usage patterns; and tools to enhance your development environment.



Sample gallery apps

WinUI 3 Gallery

The WinUI 3 Gallery app showcases all the XAML UI components in an interactive format. This app is the interactive companion to the Fluent Design Guidelines and has examples of WinUI 3 controls, features, and styles.

You can get the app from the Microsoft Store or get the source code on GitHub at microsoft/WinUI-Gallery.

Input & Composition Gallery

Use this sample app to browse through a collection of samples showing creative ways to customize and differentiate your app, then check out the accompanying code on GitHub to see how it was made. It showcases a variety of Microsoft.UI.Composition and Microsoft.UI.Input APIs, the building blocks that make up the Fluent Design System.

You can get the app from the Microsoft Store or get the source code on GitHub at microsoft/WindowsCompositionSamples.

Toolkits and helpers

Windows Community Toolkit

The Windows Community Toolkit is a collection of helper functions, custom controls, and app services. It simplifies and demonstrates common developer tasks when building apps for Windows. See Get started with the Windows Community Toolkit for detailed information about using the toolkit.

You can get the *Windows Community Toolkit Gallery* app from the Microsoft Store to see the controls in an actual app or get the source code on GitHub at CommunityToolkit/Windows.

Template Studio

Template Studio for WinUI accelerates the creation of new WinUI apps using a wizard-based UI. It's available to create apps using C# and the MVVM Toolkit.

You can get the extension from the Visual Studio Marketplace or get the source code on GitHub at microsoft/TemplateStudio.

> **Important**
>
> Template Studio for WinUI only creates apps that use the MVVM design pattern. It does not support creating apps that use the standard code-behind pattern.

Windows App SDK / WinUI 3 samples

The samples in this list demonstrate features from the Windows App SDK and WinUI 3. See our Samples Browser for a more extensive catalog of samples.

Most of the samples identified in this list contain Solution (`.sln`) files that can be opened in Visual Studio. Refer to each resource's `Readme` for additional instructions.

You can find these sample in the main Windows App SDK samples repository on GitHub at microsoft/WindowsAppSDK-Samples

Samples that demonstrate specific tasks

Expand table

Sample	Task
Activation	**Handle app activation kinds**. App activiation APIs control the way that

Sample	Task
	your app handles activation kinds like `Launch`, `File`, and `Protocol`.
App Instancing	**Determine application instancing behavior**. App instancing APIs control whether or not users can run multiple instances of your application at the same time.
Power Notifications	**Use state notifications**. State notifications allow you to detect when the user's device enters specific states, such as low power mode.
Restart	**Programatically restart your app**. This sample makes use of the Windows App SDK Restart APIs.
Resource Management	**Tailor your app to the user and device settings**. MRT Core resource management APIs allow you to adapt resource utilization to specific situations.
Deployment Manager	**Call the Deployment API** to ensure that Windows application framework components are up to date.
Installer	**Launch the Windows App SDK installer** without using a console window.
TextRendering with DWriteCore	**Render text** using DWriteCore APIs.
Unpackaged	**Windows App SDK deployment guide for framework-dependent apps packaged with external location or unpackaged**, an alternative to packaged app deployment architecture.
Dynamic Dependencies	Demonstrates the techniques shown in Use the dynamic dependency API to reference MSIX packages at run time.
Push Notifications	**Add push notifications to your app**. Push Notifications can be used to send device-native app notifications to users.
App Notifications	**Add toast notifications to your app**. See App Notifications to learn more.
Custom Controls	**Add custom C#/WinRT controls to your app** using the patterns demonstrated in Author Windows Runtime components with C#/WinRT.
Windowing	**Add windowing support to your app** to create/hide new windows, customize titlebars, and more. See Manage App Windows to learn more.

Development environment

If you've completed the steps in Get started with WinUI, then you've already installed Visual Studio and enabled Developer Mode. These links provide more information about

these tools to take you beyond the basics.

Developer Mode

Windows has a special mode for developers that adjusts security settings in order let you to run the apps you're working on. For more information, see Enable your device for development and Developer Mode features and debugging.

Visual Studio

The preferred development tool of many Windows developers, Visual Studio will let you create projects for Windows, and many other platforms. It is a powerful IDE that can help you write, debug, and deploy your apps. For more information about the many things you can do with Visual Studio, see the Visual Studio documentation.

Visual Studio Code

A highly extensible editor, Visual Studio Code can be customized to support almost any kind of development you can think of. It is a great choice for writing apps for Windows, and other platforms. For more information, see the Visual Studio Code documentation.

Additional tools

These additional tools will help you set up your development environment on Windows.

Dev Drive

In order to speed up common development tasks, you can create a specially formatted drive (a Dev Drive) that is used to store your projects.

Windows Terminal

Windows Terminal is a modern host application for the command-line shells you already love, like Command Prompt, PowerShell, and bash (via WSL).

Windows Subsystem for Linux (WSL)

WSL lets you run Linux distributions on Windows. This is a great way to use open source tools to develop apps for Windows.

Language documentation

Most WinUI apps are written in C# or C++. These guides contain articles, tutorials, and code samples to help you get started with these languages.

- C# language documentation
- C++ language documentation
- C++/WinRT language documentation

Next steps

Now is also a good time to create a developer account. Among other things, this will allow you to publish your apps to the Microsoft Store. Here is how you do that: Create a developer account

- Windows Developer FAQ

Windows Application Development - Best Practices

Article • 03/15/2023

The best practices in this document will help you build great Windows apps that reach and delight ~1.5 billion diverse PC users around the world. This document is divided into the following sections:

1. **User experience**: Guidance in this section will help you improve the look, feel, and usability of your apps.
2. **Performance and fundamentals**: Guidance in this section will help you improve your app's performance and resource utilization.
3. **Operating system / hardware optimization**: Guidance in this section will help you optimize your packaging and distribution for a variety of hardware configurations.
4. **Application discovery and management**: Guidance in this section will make it easier for users to discover, install, update, and uninstall your app.
5. **Accessibility**: Guidance in this section will help you build accessible and inclusive experiences.
6. **Security and privacy**: Guidance in this section will help you mitigate security risks and meet your users' privacy needs.

User experience (UX)

Windows 11 marks a visual evolution of the Windows operating system that improves the look, feel, and usability of Windows. Our studies show that users have high expectations for Windows apps:

- They expect Windows apps to work with a complete range of inputs.
- They expect design and interaction patterns that look and feel native on current and future devices.
- They expect support for modern windowing workflows and shell integration points.

When applications adhere to Windows styles and standard Windows behaviors, users don't have to re-learn interaction patterns. This makes it much easier for users to use your app. An app that looks great can create a great first impression, but an app that's also easy to use and helps the user accomplish their goals will create a great lasting impression.

Windows 11 is built on the Windows 11 design principles. Following these guidelines as you build your apps will help you meet your customers' expectations of a great app

experience. When thinking about incorporating the latest and recommended Windows application UI/UX patterns into your Windows applications, we recommend that you focus on these 5 areas:

- Layout
- UI interaction
- Visual style
- Window behavior
- Shell integration points

WinUI 3 provides built-in support for many of these experiences and styles through its **common controls**. If you aren't able to use WinUI 3, consider emulating the styles demonstrated in our design toolkits and WinUI Gallery.

Layout

Windows applications run on a variety of configurations that match users' needs. Test your application's panes and/or pages across a variety of dimensions, devices, window sizes, DPI settings, and scale settings. Your application should work as expected even when resized down to small dimensions.

DPI awareness

WinUI applications automatically scale for each display that they're running on. Other Windows programming technologies (Win32, WinForms, WPF, etc.) don't automatically handle per-monitor DPI scaling. Without additional work to support per-monitor DPI scaling for these technologies, applications may appear blurry or incorrectly-sized. See High DPI Desktop Application Development on Windows for more information.

Responsive layout

Use responsive design techniques to optimize your app pages for different window sizes. Follow the guidelines for panning or scrolling to ensure that users can always access your content, no matter how small the app window gets.

UI interaction

Windows users can choose from a wide variety of input devices to interact with your application, and Windows has specific system experiences that people are accustomed to using. When your application adheres to these experiences, your users can use your

application reliably. When your app doesn't follow these conventions, users may find it confusing or frustrating.

On-object commanding

Use on-object commanding such as context menus, swipe commands, and keyboard shortcuts. Windows 11 improves the behavior of the right-click context menu, so if your app creates context menus, refer to the latest context menu integration guidance. WinUI text controls automatically expose cut/copy/paste commands, but other controls may need extra work to support these commands.

Text interaction

Whenever there is text in an application, users expect that they can select and copy it. If the text is editable, they expect that they can cut and paste, as well. By providing consistent shortcuts to users, you let them complete their tasks more efficiently. Ensure that these actions can be performed using keyboard, mouse or trackpad, touch, and pen.

Panning & Scrolling

It is uncommon for an application's UI to fit entirely inside a single page that does not need to scroll. Even if there are only a few UI elements, users can freely resize the app Window and cause some UI elements to be hidden. Ensure that your application's UI properly supports scrolling and panning (using keyboard, mouse or trackpad, touch, and pen) to let users access any UI elements that might have moved out of the visible window area.

Visual style

Windows 11 is built on the Windows 11 design principles: Effortless, Calm, Personal, Familiar, and Complete + Coherent. We believe experiences that follow these principles bring great user experiences on Windows.

Materials: Acrylic and Mica

Acrylic and Mica are visual materials that give interactive UI controls a distinct "occluded" visual style. Use Acrylic to apply a semi-transparent style to transient surfaces like context menus, flyouts, and other elements that can be light-dismissed. Use Mica to add a subtle adaptive tint to long-lived UI surfaces like the title bar.

More information about Acrylic and Mica materials can be found in Things you can do to make your app great on Windows 11.

Dark and Light themes

Dark and Light themes give users a way to adapt your app to their visual preferences. Windows 11 updates the color tones to be softer on the eyes by avoiding pure white and black, which makes the colors much more delightful. WinUI supports switching between Dark and Light themes by default (see XAML theme resources). For Win32 apps, see Support Dark and Light themes in Win32 apps. (The title bar in Win32 apps does not automatically adapt to the Dark theme. Be sure to follow the title bar guidance in the article).

Refreshed UI elements

Windows 11 geometry has been crafted to support modern app experiences. Progressively rounded corners, nested elements, and consistent gutters combine to create a soft, calm, and approachable effect that emphasizes unity of purpose and ease of use.

The visual and behavioral changes are built in to WinUI 3. Use WinUI 3 where you can to take advantage of the work that has already been done. If you aren't able to use WinUI 3, consider emulating the styles demonstrated in our design toolkits and WinUI Gallery.

Context menu

A context menu is a shortcut menu that the user invokes with a right-click or tap & hold action to reveal a menu of commands relevant to the context of the control the user is interacting with. Users expect the appearance and behavior of context menus to be coherent across Windows. Use platform-provided context menus whenever possible to keep them consistent with the rest of the system.

Iconography and typography

Windows 11 has updated icons ("Segoe Fluent Icons"), improved support for animated icons, and a new UI font ("Segoe UI Variable"). We recommend that you use these new icons and font whenever possible to be coherent on Windows 11. The new font brings much softer geometry and makes the text much more legible.

More information about iconography and typography on Windows can be found in Things you can do to make your app great on Windows 11.

Window behavior and style

Applications run in a frame provided by Windows, and users expect the built-in Windows look and behaviors to be consistent across app windows. Consider supporting the features listed here to ensure that your app looks and functions as users expect on Windows 11.

Snap Layout

Window snapping is greatly enhanced in Windows 11, and the Snap Layout menu is a new feature to help users discover and use the power of window snapping. Use the Snap Layout menu to test your app in different Snap Layouts and ensure your app supports different snap sizes, like 1/2, 1/3, and 1/4 screen.

If the Snap Layout menu doesn't appear for your app by default, see Support snap layouts for desktop apps on Windows 11 for some steps you can take to enable it.

Title bar and caption buttons

The title bar and caption buttons (minimize, maximize, close) are how users interact with Windows to resize, move, and close app windows. Having a consistent experience will help people use your application smoothly. See Windows app title bar to learn about title bar and caption button design for Windows.

You can use the Windows App SDK APIs to integrate app content with the title bar in WinUI 3, .NET, WinForms, and WPF apps.

Rounded corners

In most cases, your app's window will have rounded corners by default on Windows 11. If you've customized your app window and don't have rounded corners, see Apply rounded corners in desktop apps for Windows 11 for some things you can do. You should also avoid customizing window borders and shadows, which can prevent the system from rounding the window corners.

Shell integration points

Windows shell integration lets users benefit from your app even when its not running in the foreground or even visible on-screen. When your app integrates well with Windows, it becomes part of the users workflow with other apps and helps create a seamless experience.

Toast notifications

Toast notifications are the Windows notifications that appear at the bottom of the user's screen and in the Notification Center.

- Notifications should be personalized, actionable, and useful to your users. Try to give your users what they want, not what you want them to know.
- Notifications shouldn't be noisy. Too many interruptions from your app leads to users turning off this critical communication channel for your app.
- Respond to the user's intent. Selecting a notification should launch your app in the notification's context. The only exception to this guideline is when the user selects a button on your notification that's attached to a background task, such as a quick reply.
- Provide a consistent Notification Center experience. Keep Notification Center tidy by clearing out old notifications.

For more information about toast notifications, see Notifications design basics.

Performance & fundamentals

Windows users expect Windows apps to exhibit great performance and fundamentals. As you design and build your app, it is important to keep in mind optimizing for memory usage, power consumption, responsiveness, reliability, and the impact on long-term sustainability. Allocating time to test and measure your application's fundamentals and performance will ensure that your users have a first-class experience.

Following the best practices in this section will help you meet your customers' expectations across these criteria.

- Minimize application memory usage:
  - Reduce foreground memory usage.
  - Minimize background work.
  - Release resources while in the background.
  - Ensure your application does not leak memory.
- Make efficient use of the disk footprint:
  - Enable "pay for play" for optional functionality.

    - Ensure any caches are sized efficiently.
    - Implement new experiences in a disk-efficient manner.
    - Optimize individual binary sizes where possible.

- Improve power consumption and battery life by minimizing background work:
    - Do not wake the CPU or use system resources while in the background.

- Improve the responsiveness of your app's launch and key interactions
    - Define your key interaction scenarios and add ETW events to measure.
    - Set goals based on the interaction class associated with user expectations.

To learn more, see the Performance and fundamentals overview, which will cover questions such as "What is application performance and why is it important?" or "What tools can I use to measure Windows application performance?", as well as linking to case studies, related blogs, support communities, and information on how performance engineering intersects with sustainability--reducing the impact your application will have on our planet.

Operating system / hardware optimization

Windows apps can be built, packaged, and delivered in a variety of ways. The best practices in this section will help you optimize these aspects of your application across hardware configurations.

MSIX app attach and Azure Virtual Desktop

If you want your app to run best in an enterprise environment, add support for MSIX app attach.

MSIX app attach lets you deliver MSIX applications to both physical and virtual machines. It's made specifically for Azure Virtual Desktop (AVD), a desktop and app virtualization service that runs on the cloud. Using MSIX app attach with AVD can help you improve sign-in times for users, and it can reduce infrastructure costs for your enterprise.

Windows on Arm

Windows can run on Arm devices. Arm PCs benefit from extended battery life and integrated support for mobile data networks. These PCs also provide great application compatibility and allow you to run your existing `x86` and `x64` applications unmodified.

For best performance, you should enable your apps to take full advantage of the energy-efficient Arm processor architecture by either building a full Arm version or by optimizing the parts of the codebase that would benefit most from native performance. For more information on these techniques, refer to Windows on Arm and Arm64EC for Windows 11 apps on Arm.

Push notifications

Push notifications allow you send information from your cloud service to your app in a performance-optimized way. Push notifications include raw notifications, badge notifications, and toast notifications sent from your cloud service.

- Use push notifications to wake up the app/client rather than always keeping it running to optimize performance on the user's device.
- Notification channels are not meant to be used to send advertisements.
- Respect `retry-after` headers – this protects our service and ensures notification delivery success.
- Remove expired/revoked channels from the system. Windows Notification Service (WNS) does not process requests for expired/revoked channels.
- Avoid sudden, large bursts of requests to WNS. This can lead to throttled responses.
- Utilize the `MS-CV` header. This will help with end-to-end traceability and diagnostics.
- Have a back-up mechanism for when notifications don't work.
- Use Azure Notification Hubs (ANH). ANH gives you access to engagement features like targeting audiences, scheduling notifications, and broadcasting notifications. If you're a Windows-only developer today, using ANH will make it easy for you to transition your notifications infrastructure to other platforms in the future.

Application discovery and management

Reliable installation, update, and uninstallation experiences are important pieces of a consistent, high-quality user experience. The following best practices will help ensure that your application leaves a good impression when discovered and managed by users:

Application discovery

- Listing your app on Microsoft Store can make your app more discoverable for users.

- If you're hosting your app across multiple channels (for example - on a website and on the Microsoft Store), your application should have a consistent application identity and update mechanism across all channels.
- Distribute your app through the Microsoft Store to make it more discoverable for users. Note that Store apps are made available to users through the Windows Package Manager WinGet. If you don't publish to the Microsoft Store, you can still make your app easily discoverable in WinGet via the WinGet repository.

Installation and uninstallation

- Support a per-user install. This will enable users to install more easily and avoid UAC prompts.
- Ensure that your application's installation is error free, transparent, and thoughtful about its file management. Your application's installation shouldn't leave any temporary files behind.
- Avoid requiring elevated permissions to install and requiring operating system reboots when possible.
- Support silent installation. This is important for app manageability in enterprise environments.
- Ensure your app is listed in the Apps -> Installed Apps list.
- Consider using MSIX to ensure that users experience a seamless installation, update, and uninstallation experience. MSIX automatically removes the app binaries and data. For information about how packaged apps handle files and registry entries, see Understanding how packaged desktop apps run on Windows.
- For unpackaged apps, ensure that your application can be easily uninstalled through the Apps -> Installed Apps list in Settings. When your application is uninstalled, ensure that Start menu entries, files, directories, registry entries, and temporary files are also removed. Consider giving your users the option to preserve their data when they uninstall your application.
- Ensure that during uninstallation your app removes all binaries and application data. User-created content should be stored in locations like `Documents`, which can then be retained by users even after the app is uninstalled.
- Avoid installing or updating system binaries that may require a reboot.
- Integrate with RestartManager to save and restore state between OS updates.

Updates

- Support an update mechanism that allows your app to restart when its convenient for the user. Consider using the Windows App SDK Restart APIs to manage app behavior for WinUI 3 apps.

- Ensure that your update mechanism downloads only the essential changed components that need to be updated. This can minimize the network bandwidth required.
- Ensure that you provide a way to update and repair your app. Consider MSIX, which automatically handles update repair. For more information, see Auto-update and repair apps.
- Consider push notification-based updates or checking for available updates at app startup or at restart.

- MSIX documentation
- Windows Installer Best Practices

Accessibility

Accessible Windows applications support rich and inclusive experiences for as many people as possible, including those with disabilities (both temporary and permanent), personal preferences, specific work styles, or situational constraints (such as shared work spaces, driving, cooking, glare, and so on).

In fact, the World Health Organization defines disability not as a personal characteristic, but rather as a mismatched interaction between a person and the physical and digital world around them.

> ## Accessibility is good for both people and business
>
> **Accessibility is a responsibility**
>
> More than 1 billion people worldwide experience some form of disability. However, only 1 in 10 have access to the assistive technology needed to fully participate in our economies and societies. Typically, the unemployment rate for people with disabilities is twice that of people without a disability. And disabilities—whether situational, temporary, or permanent—can affect any of us at any time.
>
> **Accessibility is an opportunity**
>
> According to the Microsoft Accessibility Approach Datasheet: Inclusive organizations that embrace best practices for employing and supporting persons with disabilities in the workplace outperform their peers and do better at attracting and keeping top talent. Millennials, who will be 75% of the global workforce by

> 2020, typically choose employers who reflect their values. Diversity and inclusion top that list.

Incorporating accessibility

Incorporating accessibility into your Windows apps can maximize user engagement, increase product satisfaction, and encourage product loyalty. Proactively designing and implementing accessible experiences typically results in reduced development and maintenance costs over the long-term.

For detailed guidance on building accessible Windows apps, see Accessibility in Windows 11 and Windows 10.

Accessibility testing

Accessibility Insights is a powerful suite of tools for developers to test the accessibility of their apps and services. Here are some tools to leverage in testing accessibility:

1. Inspect in Accessibility Insights for Windows. Inspect the accessibility tree to find low-hanging fruit like hints in labels, incorrect roles, etc.
2. Event monitoring in Accessibility Insights for Windows · Accessibility Insights. See Supporting UI Automation Control Types for more info on event monitoring.
3. Run Accessibility Insights automated checks in your PRs or CI/CD. For more info, see axe-pipelines-samples.
4. Fix all bugs you find, they all have direct impact on accessibility.

Security and privacy

An insecure application can be an entry point that allows an attacker to perform malicious activities. Even if your app doesn't have security bugs, attackers can use your app to initiate their attacks through phishing and other forms of social engineering that violate security and privacy boundaries. The best practices in this section will help you mitigate risks related to security and user privacy.

Security guidelines

- Follow the Security Development Lifecycle for all development.
  - Threat modeling can help you avoid security flaws.
  - Using secure libraries, languages, and tools minimizes implementation flaws.
  - Secure defaults can prevent security issues caused by user error.
- Don't require administrative privileges to *install* your app.

    - Ideally, your app should support both administrative installs and per-user installs.
    - Using MSIX packaging is one way to achieve this.
- Don't require administrative privileges to *run* your app.
    - If there are certain features that need administrative privileges, consider separating them into their own processes to reduce attack surface.
- Prefer to use languages with guaranteed memory safety (such as C#, JavaScript, or Rust), especially for risky code paths (like parsing untrusted data).
- Use all security mitigations provided by your compiler and toolset (see Security Features In Microsoft Visual C++ for Visual C++).
- Always use your chosen language or framework's standard libraries for cryptography and other security-sensitive code. *Do not try to build your own*.
- Digitally sign all components of your application – not just the installer, but also the uninstaller (if you have one). Also sign all the EXE, DLL, and other executable files that make up your app.
    - Digital signatures enable the user to verify the authenticity of your app and allow Enterprise admins to secure their devices using Windows Defender Application Control.
    - Using MSIX packaging is one way to achieve this.
- Ensure all network communication is over a secure transport, such as SSL.
- Provide guardrails or other mitigations that can help protect users from accidentally performing harmful actions, even when coerced into doing so by attackers.
    - Simple "Are you sure you want to do *X*? *Yes / No*" dialogs are typically not effective, because users have been conditioned to click "Yes."

Most modern apps collect and use a large amount of data – including personal data – for various reasons. Telemetry, product improvement, and monetization are three common reasons for using data, but users and regulators alike are becoming more sensitive to the privacy implications of these practices. They expect transparency and control over the data collected and used by apps. Use the following tips to help meet the privacy needs of your users.

Privacy guidelines

- Ensure that your app provides an accurate Privacy Policy. Ideally, provide both a summary document written for a casual audience (your users) in addition to a long-form legal policy (written for your lawyers).
- Familiarize yourself with privacy regulations in the markets where your app will be available, and ensure your app meets or exceeds any requirements for disclosure, usage rights, deletion requests, etc.

- Ensure you're collecting the least amount of personal data needed to complete your app's experiences.
  - Don't collect data "just in case" – there should be a valid reason for collecting all data, e.g. to improve the customer's experience or to facilitate monetization.
- Always get the user's consent before collecting and storing personal data and provide the user with an easy way to revert their decision in the future. Avoid "dark patterns" such as making the "Yes" button larger or more prominent than the "No" button in a consent dialog.
  - Consult with applicable regulations to determine what specific disclosures and consent is required for specified kinds of data. For example, some regions may allow users to view, change, or delete the data you have stored about them.
- If you must transmit data over the network, always use secured connections, e.g. over TLS.
- Avoid storing personal data in a centralized location (e.g. website). If you must store personal data, minimize the amount of data you store, store it only for as long as strictly necessary, and ensure it is securely encrypted.
- Verify that any 3rd-party libraries or SDKs you use also have good privacy practices. Note this is *not* limited to just advertising SDKs – any library that connects to the internet may impact the privacy of your app's users.

Windows developer FAQ

FAQ

This article is meant to promote a common understanding of the Windows development experience and product direction.

Today's Windows app development landscape offers a variety of frameworks and technologies to choose from. This FAQ provides guidance on how to decide which framework to use for your Windows app development projects. It covers the following topics:

- Getting started and the Windows app development landscape.
- Native Windows-only app development with WinUI, Windows Presentation Foundation (WPF), and Windows Forms (WinForms).
- The Windows Software Development Kit (SDK) and Windows App SDK.
- Targeting Windows as part of your cross-platform development strategy.
- Hybrid and web app development with .NET MAUI, Blazor, and ASP.NET Core.
- How to choose an approach while understanding Microsoft's investments.

The Windows app development landscape

Where can I find a straightforward overview of Windows development technologies?

For a great review of today's options for Windows developers, watch the most recent Windows Dev Chat episode, Choosing your ideal dev platform, where they discuss WinUI, .NET MAUI, React Native, Blazor, and Progressive Web Apps (PWAs).

You can also refer to the overview of app development options for Windows developers.

Why is client app development still crucial for modern digital transformation in the era of cloud services?

In the age of cloud services, client app development remains a critical component of modern digital transformation. For developers, building client applications is essential not just for reach but for delivering responsive, meaningful interactions on user devices.

Here's why client apps still matter:

- **Device Reach:** With over 1.5 billion Windows devices and more than 5 billion Android and iOS devices globally, client apps let you bring your applications directly to users on their devices of choice.
- **Gateway to Intelligent Services:** Client apps are often the first interaction users have with your services. They offer a rich, interactive interface that allows you to showcase intelligent features and differentiate your product from others.
- **Scalability with Cloud Integration:** A well-integrated client app can sync effortlessly with backend cloud services, enabling real-time data access and seamless scalability as your user base grows.
- **Enhanced Productivity and User Loyalty:** A thoughtfully designed app can enhance productivity and keep users engaged with your product or service over time.

Native Windows-only app development

What is the Windows App SDK?

The Windows App SDK is a Windows application development platform that allows you to create beautiful, modern, backwards-compatible (down to Windows 10 1809) desktop apps. WinUI 3 is the UI framework that ships with Windows App SDK.

What's the difference between the Windows App SDK and the Windows SDK?

Both are software development kits (SDKs) that let you build Windows apps.

The **Windows App SDK** is a new development platform that lets you build modern desktop apps that can be installed across Windows versions (down to Windows 10 1809). When you use Windows App SDK to build an app, you'll have access to the latest Windows development platform features. The Windows App SDK includes WinUI 3.

The **Windows SDK** is a development platform that lets you build UWP apps and Win32/desktop apps. It's designed around Windows APIs that are coupled to particular versions of the OS.

The Windows App SDK doesn't replace the Windows SDK. Instead, the Windows App SDK is a complement to the Windows SDK. It provides a convenient, OS-decoupled abstraction around the rich catalogue of Windows OS APIs that you can already access using the Windows SDK. When you build apps with Windows App SDK, you might end

up using some Windows SDK APIs depending on the functionality that you need. Over time, more Windows SDK functionality will be lifted into the Windows App SDK.

I'm building a new team to develop a Windows-only app. Why should I choose to develop with a native Windows framework like WinUI, WPF, or WinForms?

Here are some reasons to choose a native Windows framework for your Windows-only app:

- **Performance:** Native Windows frameworks are optimized to leverage the full power of today's Windows hardware and provide fast and responsive user experiences.
- **Integration:** Windows ships with wide varieties of APIs to build sophisticated experiences only available on Windows. The native frameworks provide deep integration with these features and APIs.
- **Native user experience:** Native Windows frameworks provide a consistent user experience across Windows devices, ensuring that your app looks and works great on all Windows devices.
- **Offline support:** Native Windows frameworks provide support for offline scenarios, enabling your app to work even when the user is not connected to the internet.
- **Monetization:** Native Windows frameworks are actively maintained and supported by Microsoft, ensuring that you have access to the latest updates and features.

Which framework should I use to leverage Microsoft's latest investments in Windows app development?

If you're building a new Windows-only app, we recommend using WinUI. WinUI is the latest native UI framework for Windows app development and is designed to work across a wide range of Windows devices. WinUI provides a modern and flexible UI framework that enables you to create visually appealing and interactive Windows apps. WinUI is part of the Windows App SDK and is designed to work best with the latest versions of Windows.

Can I use Windows App SDK / WinUI in my existing Windows app?

Note that WinUI (a UI framework) ships with Windows App SDK (a Windows platform development framework).

Generally speaking, you can't use WinUI unless you're ready to migrate your UI framework entirely. We're working on a feature called XAML islands that lets you host WinUI content in other UI frameworks (WPF, Win32).

You should be able to use elements of the Windows App SDK in any desktop app, depending on how your existing app was built. UWP apps are not supported by Windows App SDK.

This means that **WPF/MFC/WinForms** apps can use Windows App SDK APIs that are not related to WinUI. Examples of such APIs include App Lifecycle, Windowing, and Toast Notifications.

See Use the Windows App SDK in an existing project for more information.

Do I need to use Visual Studio to build WinUI apps?

We strongly recommend using Visual Studio 2022 versions 17.10 and above to develop WinUI apps. Using the latest version of Visual Studio will give you access to rich development features like Hot Reload. The latest Visual Studio installers include a **Windows application development** workload, making it easy to get started with WinUI development.

You may be able to use other IDEs and development workflows, but Visual Studio is currently the only officially supported IDE for WinUI. Note that MSBuild is required to compile projects that use XAML or WinUI.

When I build an app using Windows App SDK and WinUI 3, am I building a "WinUI app"?

Yes - "WinUI app" is the term that we recommend you use. WinUI 3 apps are generally referred to as "WinUI apps", as WinUI 2 is not a type of app but a set of components that can be used in UWP apps.

Can I incrementally update my UWP app with WinUI 2 controls to WinUI 3 by gradually

replacing WinUI 2 components with WinUI 3 components?

No. Windows App SDK can't be used in UWP apps, and WinUI 2 can't be mixed with WinUI 3. See Migrate from UWP to the Windows App SDK.

How hard is it to migrate a UWP app to WinUI?

Migrating UI components is generally straightforward (for C# and C++/WinRT). Otherwise, the cost of migrating from UWP to WinUI will depend primarily on these factors:

1. **Project file and MSBuild customization:** Migrating your project might require a significant level of effort, depending on whether you use advanced MSBuild features.
2. **.NET API migration:** If your UWP app relies on .NET, then you'll need to upgrade to .NET 6 or later. In most cases, adopting .NET 6 is straightfoward.
3. **UI component libraries:** If you use UI component libraries, then you'll need new versions of them that target WinUI 3.
4. If your UWP source code is written in the now-superseded C++/CX, then some source code porting will be involved. See Move to C++/WinRT from C++/CX.

For more info about UWP migration, see Migrate from UWP to the Windows App SDK.

If I have an existing UWP app in the Store, can I publish a new packaged WinUI app using the same identifiers?

Yes, upgraded apps can be published without having to update your application's identity. Users who have the old version will get updated to the new version. This guidance applies only to desktop apps. Xbox, HoloLens, and Surface Hub apps can't migrate to WinUI.

How do I package/distribute my WinUI app?

See Deployment overview.

Where can I find Windows App SDK migration guidance?

See Migrate from UWP to the Windows App SDK.

Do I need to use XAML markup if I want to use WinUI?

No. UI controls can be created in code. But there are many benefits to representing your WinUI user interface in the form of declarative XAML markup, such as improved developer experience.

If you're migrating from UWP to WinUI, you'll probably be able to reuse a lot of your XAML markup and UI-related code (but you'll have to update some of the syntax). If you're migrating from WPF to WinUI, you'll be able to reuse a lot of the concepts, but the control set and APIs will be different.

Does Visual Studio have a design surface / UI designer for WinUI?

Not yet. We recognize that this is a gap in the WinUI developer experience. Tools like XAML Hot Reload can help in many scenarios. Work has started on a Visual Studio UI designer for WinUI in Windows App SDK 1.7, but there isn't a timeline for the release of this feature yet.

Does Windows App SDK include WinUI 3?

Yes. WinUI 3 ships as a part of the Windows App SDK.

Does Windows App SDK include WinUI 2?

No. WinUI 2 is part of the UWP platform.

Are WinUI 2 and WinUI 3 built on the same technology?

Not quite. Although WinUI 3 started from the WinUI 2 codebase, they are distinct technologies. Both WinUI 2 and WinUI 3 are XAML-based UI frameworks that work across .NET and C++. Note that WinUI 2 and WinUI 3 are not compatible with each other.

Can I use WinUI 3 without using Windows App SDK?

No. WinUI 3 ships as part of the Windows App SDK.

Can I use WinUI 3 in an unpackaged app?

Yes. All technologies in the Windows App SDK work in unpackaged apps, including WinUI 3.

What's the difference between XAML Islands and WinUI 3?

XAML Islands allow you to host modern WinUI controls alongside existing Win32 UI from other frameworks, such as WinForms and WPF. Today, XAML Islands are supported with *most* system XAML and WinUI 2 controls. See Host WinRT XAML controls in desktop apps (XAML Islands) for more information. XAML Islands support for WinUI 3 controls is available starting in Windows App SDK 1.4.

If I create a WinUI app, will it look modern on both Windows 11 and Windows 10?

Yes, your app's UI will inherit the latest Fluent UI design principles on all supported versions of Windows 11 and Windows 10 down to version 1809 in both packaged and unpackaged scenarios.

Can I use Mica or Acrylic backgrounds in apps built with Windows App SDK?

Yes. See Apply Mica or Acrylic materials in desktop apps for Windows 11.

Where can I find WinUI samples?

See Sample and resources. Some notable repositories:

- WindowsAppSDK-Samples : Demonstrates how to use specific Windows App SDK API sets.
- WinUI 3 Demos : Contains demos used during Microsoft's WinUI presentations.

- WinUI Gallery: Showcases WinUI and Windows App SDK. You can also get the WinUI Gallery in the Microsoft Store.

If I have already invested heavily in WPF, should I continue to use WPF or should I consider migrating to WinUI?

If you have already invested heavily in WPF, you can continue to use WPF for your existing apps. WPF is a mature and stable framework that is widely used by developers to build Windows desktop apps.

Consider leveraging the .NET Upgrade Assistant to migrate your .NET Framework WPF apps to the latest .NET platform. The .NET Upgrade Assistant is a tool that helps you migrate your .NET Framework apps to the latest supported versions of .NET. The .NET Upgrade Assistant analyzes your existing codebase and provides guidance on how to update your code.

If I build a new WPF app, will it look dated compared to other new Windows apps?

When developing a WPF application with .NET 9 or later, you can ensure your app matches the sleek, modern look of Windows 11. The new Fluent theme for WPF introduces a contemporary Windows 11 aesthetic to WPF applications, complete with integrated Light/Dark mode and system accent color support. This update not only modernizes the appearance of your app but also enhances user engagement by providing a polished and cohesive user experience.

My team is comfortable building WinForms apps, and it suits our needs. Should we consider migrating to WinUI or another framework?

If your team is comfortable building WinForms apps and WindForms meets your needs, you can continue to use WinForms for your existing apps. WinForms is a mature and stable framework that is widely used by developers to build Windows desktop apps.

The WinForms team is investing across features and has an active community of contributors. Some current areas of investment include:

- Async support with common controls
- Dark mode

- Layout flexibility
- Desktop security features like clipboard access

Cross-platform native development

What are some reasons for building cross-platform, native apps that target Windows?

If you're targeting users across multiple OS platforms, building cross-platform apps with .NET MAUI or React Native can provide several benefits:

- **Reach:** Building cross-platform apps allows you to reach a larger audience of users on different platforms.
- **Code reuse:** Building cross-platform apps allows you to reuse code across different platforms, reducing development time and costs. It can be prohibitively expensive to build separate apps for Windows, iOS, Android, macOS, etc.
- **Consistent user experience:** Building cross-platform apps allows you to provide a consistent user experience across different platforms, ensuring that your app looks and works great on all devices.
- **Integration:** Building cross-platform apps allows you to integrate with different platforms and services, enabling you to provide a more comprehensive user experience.

Can I be confident that .NET MAUI apps will run well on Windows?

When you build a .NET MAUI app for Windows, your output is a WinUI app. While developing, .NET MAUI provides a single .NET experience across all platforms, including Windows, but under the hood, it generates platform-specific code. This ensures that your .NET MAUI app runs well on each platform and provides a native user experience.

How can .NET MAUI provide native device APIs across every platform?

.NET MAUI provides a single .NET experience across all platforms, including Windows, iOS, Android, and macOS. .NET MAUI abstracts over 60 platform-specific APIs into a single, cross-platform API that you can use in your .NET MAUI app. These APIs cover access to storage, networking, device-specific sensors, and more. If needed, you can also

access additional platform-specific APIs using dependency injection to abstract the code for each platform.

Can I start with WinUI, and later integrate .NET MAUI if I eventually want to target cross-platform scenarios?

Not at this time. Although .NET MAUI apps use WinUI when running on Windows, we recommend starting with .NET MAUI or React Native for Desktop if you anticipate the need to target multiple platforms.

Our team has strong web front-end development skills. Should we consider using React Native for Desktop?

If your team has strong web development skills, you may want to consider using React Native for Desktop. React Native for Desktop encompasses the React Native for Windows and macOS frameworks. The motto of React Native is "Learn once, write anywhere," which means that you can use your existing web development skills to build native Windows apps using React Native. React Native for Desktop is an open-source project that enables you to build native Windows and macOS apps using React Native. React Native for Desktop provides a set of APIs that allow you to access desktop OS-specific features and capabilities in your React Native apps.

Your team can leverage their JavaScript, TypeScript, and React skills to build the UI layer, which is rendered directly to native primitives. This provides native app performance and access to the capabilities of the native platform.

Read more about getting started with React Native development for Windows in the React Native for Desktop documentation.

Are any other Windows devices supported by React Native for Desktop?

React Native apps can be deployed to all devices supported by Windows 10 and higher including PCs, tablets, 2-in-1s, Xbox, and Mixed reality devices.

What should I use if I want to build apps that work on Windows and Xbox?

If your app needs to support Xbox, HoloLens, or IoT, we recommend using UWP. Windows App SDK doesn't support these platforms. For game development, we recommend using Microsoft Game Development Kit.

What should I use if I want to build apps that work on Windows and Surface Hub?

If you're targeting both Windows and Surface hub, we recommend using UWP.

Hybrid and web development

What are hybrid apps, and why should I consider building one?

Hybrid apps blend the best of web and native app development. The core of the app is built using web technologies like HTML, CSS, and JavaScript, and then wrapped in a native container that allows the app to leverage certain native platform features and hardware. They can also be distributed through app stores.

The main advantage of hybrid apps is that they allow you to build a single app that can run on multiple native platforms and on the web, reducing development time and costs. Some examples of hybrid app development platforms answer:

- Electron for desktop apps
- Ionic for mobile apps
- .NET MAUI Blazor hybrid for cross-platform apps

How do I build native-feeling progressive web apps (PWAs) on Windows?

See Web development on Windows and Overview of Progressive Web Apps.

What is a .NET MAUI Blazor hybrid app?

With .NET MAUI, Blazor apps can also run natively on Windows, iOS, Android, and macOS. This means you can create hybrid client apps that combine Blazor and .NET

MAUI components together into a single, native client app. This provides full access to the same native platform capabilities available to any other .NET MAUI apps.

To read more about how Blazor can hosted within a .NET MAUI app, see ASP.NET Core Blazor Hybrid.

Do the web components of a .NET MAUI hybrid app need to be created with Blazor?

No, the web components of a .NET MAUI hybrid app do not need to be created with Blazor. Starting with .NET 9, .NET MAUI provides a HybridWebView control that allows you to host other JavaScript UIs in your native app.

This means you can take your Angular, React, Vue or other HTML & JavaScript web app and host it within your .NET MAUI app. The hybrid control provides interop between the C# and JavaScript layers so you can call JavaScript functions from C# and vice versa.

Can any other native app types host Blazor hybrid components?

Yes, WPF and WinForms apps can also host Blazor hybrid components. This allows you to add modern web UI components to your existing WPF and WinForms apps. Note, that this is not possible with WPF or WinForms apps built on .NET Framework.

Does my entire app need to be a hybrid app, or can I mix and match native and hybrid components?

You can mix and match native and hybrid components in your app. For example, you can build the core of your app using .NET MAUI components and then add hybrid components to provide additional functionality. This allows you to leverage the best of both worlds: the performance and capabilities of native components and the flexibility and cost savings of hybrid components.

What are my choices for building .NET-based web apps that look great on modern browsers on Windows?

Web apps have the broadest reach of any client app platform. If you want to create beautiful .NET web apps on Windows, you have several options:

- ASP.NET Core apps with Razor Pages
- ASP.NET Core MVC apps
- ASP.NET Core Blazor apps, with hosting model options including:
  - Blazor WebAssembly apps
  - Blazor Server apps

Note that the hosting model for Blazor can be configured at the component level now. So, you can have a Blazor WebAssembly component hosted in a Blazor Server app.

Read more about ASP.NET Core development options in the ASP.NET Core documentation.

Choose an approach and understand Microsoft's investments

There are so many framework options for building apps that target Windows! How do I decide?

Windows is an open platform that supports many technologies. Here are some criteria that can help you decide which platform to use:

- Are you building Windows-first or cross platform?
- Do you have experience with .NET? JavaScript? Other languages?
- Do you need to access Windows-specific APIs?
- Which framework's capabilities best match your app's requirements?
- See this table for other decision factors.

When it comes to business apps, most teams want to choose based on existing skills and what the team is comfortable using.

How do I choose the best development approach for my web app?

Some things to consider when choosing a development approach for your web app include:

- Blazor is recommended for building front-end web apps with .NET. By using Blazor, you can now build your entire front-end and back-end with .NET, saving time and money. It is particularly well-suited for enterprise line-of-business apps on today's devices.
- JavaScript web apps still make sense if you want to leverage your team's existing skills or investments in JavaScript, or if you need to integrate with existing JavaScript libraries or frameworks.
- Existing apps that use older frameworks, like Web Forms, MVC, or Razor Pages, are still supported and can continue to be developed and maintained using those frameworks.

Who is building apps with WinUI today?

Many customers are building with WinUI today, including Adobe and Apple:

- Adobe Fresco, a free drawing and painting app for Windows.
- Apple created the Apple Music, Apple TV, and Apple Devices apps with WinUI and the Windows App SDK.

Microsoft has also created several apps with WinUI, including the Windows 11 File Explorer and Photos apps.

Who is building .NET MAUI apps today?

Many customers are using .NET MAUI to build their cross-platform apps today, including Microsoft. For example, the Microsoft Azure mobile app was built using .NET MAUI.

Find out who else is building apps with .NET MAUI on the .NET customers showcase site.

Who is building WPF apps today?

Most of Microsoft Visual Studio's user interface is built with WPF. The Visual Studio IDE is a great example of a complex, high-performance WPF app.

Who is building Blazor apps today?

GE Digital's FlightPulse airline system puts sensor data and analytics into the hands of pilots to improve safety and efficiency. The backend configuration of everything the pilots see is all done with Blazor.

You can read more Blazor customer stories on the .NET site.

UWP and WinUI 2

Can UWP apps be distributed outside of the Microsoft Store?

Yes. If your MSIX package is signed, the signing certificate must be valid and trusted on the target device.

Can I mix UWP XAML UI controls with Win32, WPF, or WinForms UI controls?

Yes - XAML Islands lets you do this. Learn more about XAML Islands.

Packaging, deployment, and updates

What's the difference between apps that are packaged, unpackaged, and packaged with external location?

For definitions of apps that are packaged, unpackaged, and packaged with external location, see Deployment overview. That topic also explains the advantages and disadvantages of each option.

Will my WinUI app automatically update for end-users?

A WinUI app can be delivered through the Store, an .appinstaller file, or in your existing MSI or setup.exe package. The Store and the AppInstaller support automatic updates for end-users who have automatic updating enabled, but your MSI/setup.exe app needs to have its own updater.

Can I use Windows App SDK without using MSBuild?

Generally speaking, no. WinUI and Windows App SDK require MSBuild, which is why Visual Studio is a prerequisite to developing with WinUI and Windows App SDK. While it's technically possible to build Windows App SDK apps that don't use WinUI using other toolchains, this isn't supported.

Performance and optimization

What can I do to make my Windows app feel great to end-users?

See Make apps great for Windows.

Compatibility

Will my users ever have to update Windows to use my WinUI app?

Users who have Windows 10, version 1809 and beyond will be able to install your WinUI apps without updating their OS.

Can I target Arm64 with my WinUI app?

Yes.

Deprecations and migrations

Are UWP / WinUI 2 deprecated?

No. UWP and WinUI 2 are still supported and will receive bug, reliability, and security fixes. However, most new features and capabilities will only be added to WinUI 3.

> **Note**
>
> UWP support for .NET 9 is available in preview. This preview support provides a path for UWP apps to modernize using the latest version of .NET.
>
> There are two main goals of the .NET 9 UWP support. First, it provides a better migration path for UWP developers who want to migrate to WinUI 3. Second, it

enables developers to remove dependencies on .NET Native, so they can benefit from the latest .NET and C# features, no matter what their app model is.

For more information, see the Modernize your UWP app with preview UWP support for .NET 9 and Native AOT blog post.

When should I migrate a UWP / WinUI 2 app to WinUI 3?

UWP developers should feel no pressure to migrate their apps to the WinUI 3, if they are happy with UWP and its feature set. The best choice for some apps may be to never migrate. For apps that want to benefit from the latest Windows platform and .NET investments from Microsoft, these apps should consider moving to the Windows App SDK. See Migrate from UWP to the Windows App SDK).

When should I *not* migrate a UWP + WinUI 2 app to WinUI 3?

We recommend continuing to use UWP if you're building for Xbox, Surface Hub, or HoloLens.

Is WPF deprecated?

No. WPF is still supported, recommended, and receives feature updates as well. See the WPF roadmap on GitHub.

Is WinForms deprecated?

No. WinForms is still supported and receives feature updates. See the Windows Forms Roadmap on GitHub.

Is the Windows Runtime (WinRT) deprecated?

No. WinRT refers to an application binary interface (ABI) that lets you interop between multiple languages. WinRT is the evolution of COM. Windows App SDK provides most of its functionality through WinRT APIs.

Release notes

Where can I find release notes for Windows App SDK?

See Stable channel release notes and Preview channel release notes.

- Overview of app development options

Windows developer glossary

Article • 12/17/2024

The following glossary of terms is meant to promote a common vocabulary among Windows developers.

App lifecycle management (ALM)

Describes the management of your application's execution state: not running, running in background, running in foreground, suspended, and so on. See Windows 10 universal Windows platform (UWP) app lifecycle.

Application model

Often referred to as "app model". The combination of deployment, isolation, lifecycle, and presentation components that are unique to a given application development technology. For example: Windows App SDK / WinUI 3 apps run on the Win32 app model, while UWP / WinUI 2 run on the UWP app model.

Application packaging

Describes the way in which your app is packaged before being deployed and installed by users. An app can be packaged, unpackaged, or packaged with external location (see the Windows developer FAQ).

Bootstrapper

A redistributable component providing an API to find and load the Windows App SDK framework package for the calling process. In a packaged with external location or unpackaged app, you can opt to load the Windows App SDK framework package explicitly by calling Bootstrapper APIs such as MddBootstrapInitialize. Also see Reference the Windows App SDK framework package at run time.

C++/WinRT

C++/WinRT is a standard C++17 language projection for Windows Runtime (WinRT) APIs, implemented as a header-file-based library, and designed to provide you with first-class access to modern Windows APIs. C++/WinRT.

Dynamic Dependencies

Dynamic Dependencies makes framework packages accessible to all kinds of apps: packaged and unpackaged.

Fluent Design

Fluent Design is a design system that lets you create reusable cross-platform user experiences. Fluent 2 is the latest design system for Windows and is used by WinUI.

GitHub Copilot

An AI pair programmer that helps you write code faster and with less work in Visual Studio or Visual Studio Code (VS Code). See AI-assisted development in Visual Studio for more information.

Hot Reload

An app development feature that allows you to update your application's code and observe your changes while your application runs, eliminating the need to stop, rebuild, and re-run your apps while developing. See Write and debug running code with Hot Reload.

Hybrid app

An app that uses multiple technologies. For example, a .NET MAUI app that uses Blazor to render web content in a WebView2 control. See ASP.NET Core Blazor Hybrid for more information.

Hybrid CRT linkage

A C/C++ runtime library linkage technique that simplifies deployment. Also referred to simply as *Hybrid CRT*. See Hybrid C/C++ runtime library linkage (hybrid CRT linkage).

Managed apps

"Managed" refers to the "managed runtime" of .NET, which provides managed services such as garbage collection and security assurances. If you're building an app with .NET, you're building a managed app.

Microsoft Foundation Classes (MFC)

You can use Microsoft Foundation Classes (MFC) to create complex user interfaces with multiple controls. You can use MFC to create applications with Office-style user interfaces. See: MFC desktop applications.

MSIX (Microsoft Installer package format)

MSIX is a Windows app package format that combines the best features of MSI, .appx, App-V, and ClickOnce to provide a modern and reliable packaging experience. It's a modern application package format that lets you easily deploy your Windows applications. MSIX can be used to package apps built using Windows App SDK, Win32, WPF, or Windows Forms. When you use MSIX to deploy your apps, your app is a *packaged* app. A packaged app can check for updates, and can control when updates are applied. What is MSIX?.

Native apps

Traditionally, "native" refers to applications built without using the .NET runtime. In this case, "native" is synonymous with "unmanaged", and can be used to describe apps that manage their own memory and security concerns. Alternatively, some developers use "native" to indicate that an application has been built to run specifically on Windows, calling Windows APIs directly.

.NET MAUI

.NET Multi-platform App UI. A cross-platform framework for creating native mobile and desktop apps with C# and XAML. An evolution of `Xamarin.Forms` extended from mobile to desktop scenarios, with UI controls rebuilt from the ground up for performance and extensibility. What is .NET MAUI?.

Packaged app

For definitions of apps that are packaged, unpackaged, and packaged with external location, see Deployment overview. That topic also explains the advantages and disadvantages of each option.

Packaged app with external location

For definitions of apps that are packaged, unpackaged, and packaged with external location, see Deployment overview. That topic also explains the advantages and disadvantages of each option.

Progressive web app (PWA)

An application that you build by using web technologies, and that can be installed and can run on all devices, from one codebase. See Overview of Progressive Web Apps (PWAs) for more information about building PWAs.

Project Reunion

The codename for the Windows App SDK. No longer in use.

React Native

React Native is a development platform from Meta which allows developers to build fully native cross-platform apps using JavaScript, TypeScript, and React.

React Native for Desktop

React Native for Desktop brings React Native support to the Windows 10 and Windows 11 SDKs, enabling developers to use JavaScript to build native Windows apps for all devices supported by Windows 10 and Windows 11. This includes PCs, tablets, 2-in-1s, Xbox, Mixed reality devices, etc. The term React Native for Desktop encompasses both React Native for Windows and React Native for macOS.

Responsible AI (RAI)

A set of recommended responsible development practices to use as you create applications and features. See Developing Responsible Generative AI Applications and Features on Windows to learn more about the RAI principles and how they apply to Windows development.

Universal Windows Platform (UWP)

An application development platform and application model that uses Windows Runtime (WinRT) APIs to deliver packaged apps. UWP apps run in a sandboxed environment, and they inherit the security of the UWP platform. Learn more about UWP.

> **Note**
>
> The preferred approach for writing Windows apps is to use the Windows App SDK and WinUI. Another option is WPF.

Unmanaged app

Apps that aren't managed by the .NET runtime. If you're handling your own memory management, you're building an unmanaged app.

Unpackaged app

For definitions of apps that are packaged, unpackaged, and packaged with external location, see Deployment overview. That topic also explains the advantages and disadvantages of each option.

Visual Studio extension (VSIX)

Lets you create, package, and deploy Visual Studio extensions. Get started with the VSIX Project template.

WebView2

A control that allows app developers to embed web content (HTML/CSS/JS) in their native apps using the Microsoft Edge (Chromium) rendering engine. You can use WebView2 in WinUI 3, Win32 C++, WPF, and WinForms, and it offers a developer preview for WinUI 2 / UWP support. See Introduction to Microsoft Edge WebView2.

Windows API

Refers to the entire set of Windows APIs including Win32 APIs, COM APIs, UWP WinRT APIs, and the WinRT/Win32 APIs that are part of WinAppSDK and WinUI 3.

Windows App SDK

A set of new developer components and tools that represent the next evolution in the Windows app development platform. The successor to UWP / WinUI 2 for desktop application development. It lifts libraries from the OS into a standalone SDK that you

can use to build backwards-compatible desktop apps. See Overview of app development options.

Windows Forms

Also known as WinForms. A UI framework for building Windows desktop applications. It is a .NET wrapper over Windows user interface libraries, such as User32 and GDI+. It's a battle-tested way to create desktop applications using a visual designer within Visual Studio. See Desktop Guide (Windows Forms .NET).

Windows Presentation Foundation (WPF)

A UI framework for building Windows desktop applications. WPF applications are based on a vector graphics architecture. This enables applications to look great on high DPI monitors, as they can be infinitely scaled. See What is Windows Presentation Foundation (WPF)?.

Windows SDK

The Windows SDK is a collection of headers, libraries, metadata, and tools that allow you to build desktop and UWP Windows apps. The Windows SDK is not the same as the Windows App SDK.

WinUI

WinUI is the modern native user interface (UX) framework for both Windows desktop and UWP applications. WinUI.

WinUI 2

WinUI 2 is tightly integrated with Windows SDKs, and provides official native Windows UI controls and other user interface elements for UWP applications (and desktop applications using XAML Islands). See WinUI 2.

WinUI 3

The latest and recommended UI framework for Windows desktop apps. This framework is made available through the Windows App SDK, and has been decoupled from the Windows operating system. WinUI 3 uses Fluent Design to provide a native UX framework for Windows desktop apps. It will feel very familiar if you've worked with

WinUI 2. Note that WinUI 3 apps are commonly referred to as "WinUI apps". See WinUI 3.

XAML Islands

XAML Islands lets you host WinRT XAML controls in non-UWP desktop (Win32, WinForms, WPF) apps starting in Windows 10, version 1903. Host WinRT XAML controls in desktop apps (XAML Islands).

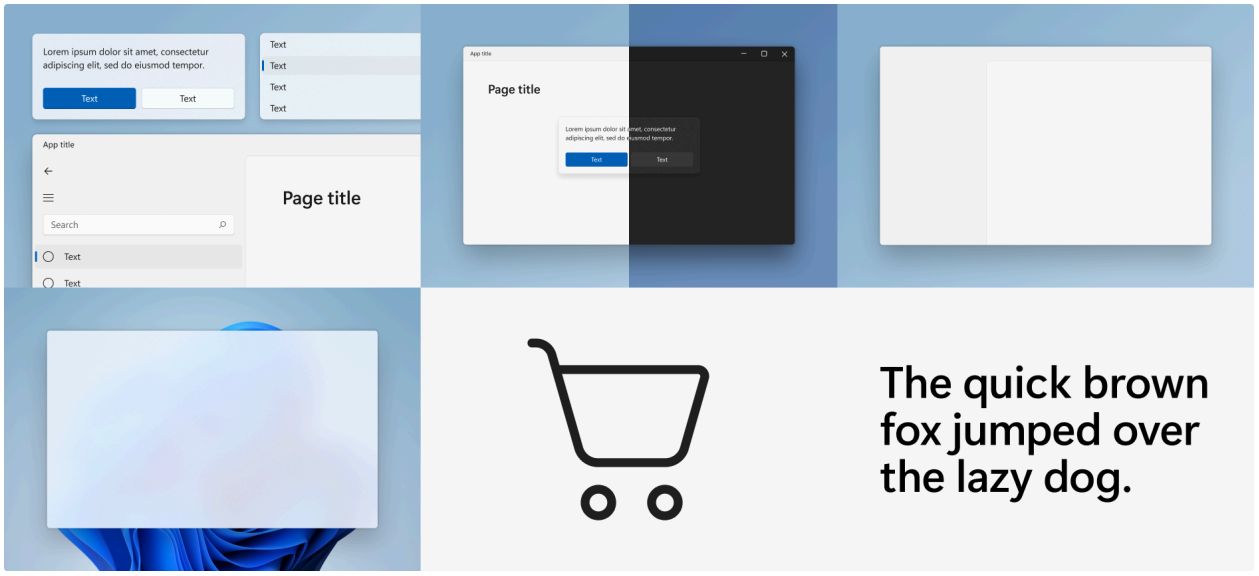
Design for Windows apps

Article • 11/05/2024

Here, you'll find design guidelines and examples for creating Windows app experiences. Windows 11 incorporates Fluent's design language and principles for a cohesive look and feel that's uniquely Microsoft.

To get the building blocks for crafting Windows experiences, use WinUI. These components incorporate Fluent's design language, so you can be confident you're building great experiences within the Fluent ecosystem.

Windows 11 design principles



Windows 11 marks a visual evolution of the operating system. We have evolved our design language alongside of Fluent to create a design that is human, universal, and truly feels like Windows.

The design principles below have guided us throughout the journey of making Windows the best-in-class implementation of Fluent.

Effortless

Windows 11 is faster and more intuitive. It's easy to do what I want, with focus and precision.

Calm

Windows 11 is softer and decluttered; it fades into the background to help me stay calm and focused. The experience feels warm, ethereal, and approachable.

Personal

Windows 11 adapts seamlessly to the way I use my device. It bends and flexes to my individual needs and preferences so that I can truly express myself.

Familiar

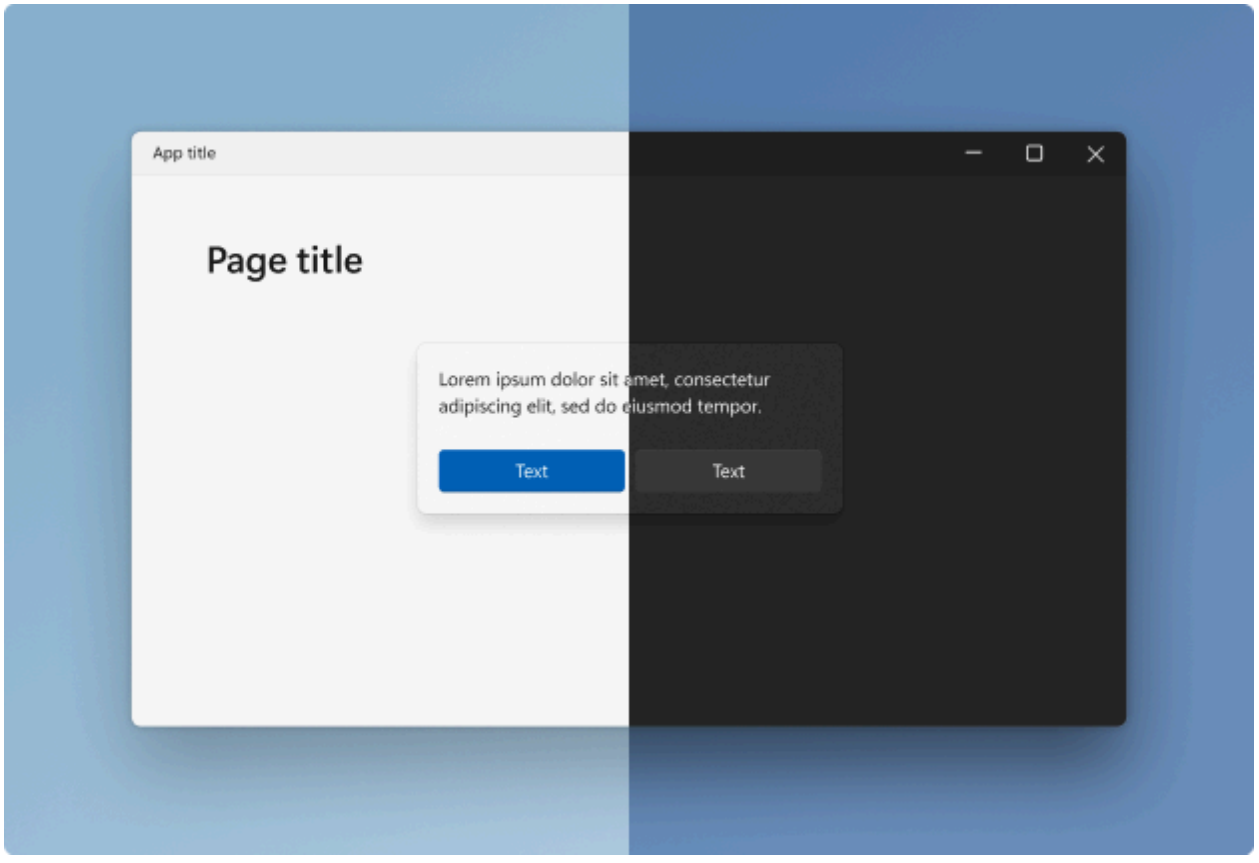
Windows 11 balances a new, refreshed look and feel with the familiarity of the Windows I already know. There is no learning curve; I can pick it up and go.

Complete + Coherent

Windows 11 offers a visually seamless experience across platforms. I can work in many platforms and still have a consistent Windows experience.

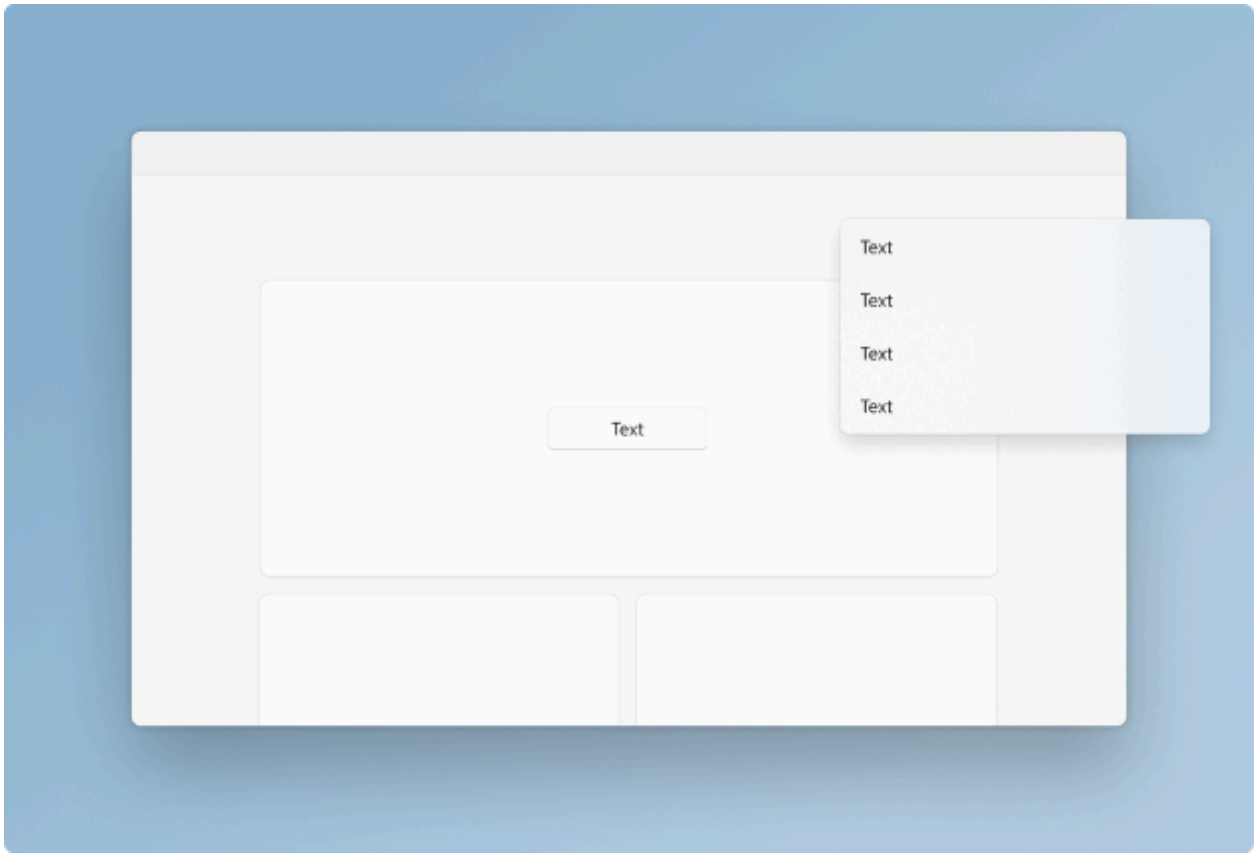
Windows 11 signature experiences

Signature experiences are the design elements Windows 11 uses to express its visual language, while maintaining a coherent look and feel across all Fluent experiences.



Color

Color helps users focus on their tasks by indicating a visual hierarchy and structure between user interface elements. Windows 11 uses color to provide a calming foundation, subtly enhancing user interactions and emphasizing significant items only when necessary.

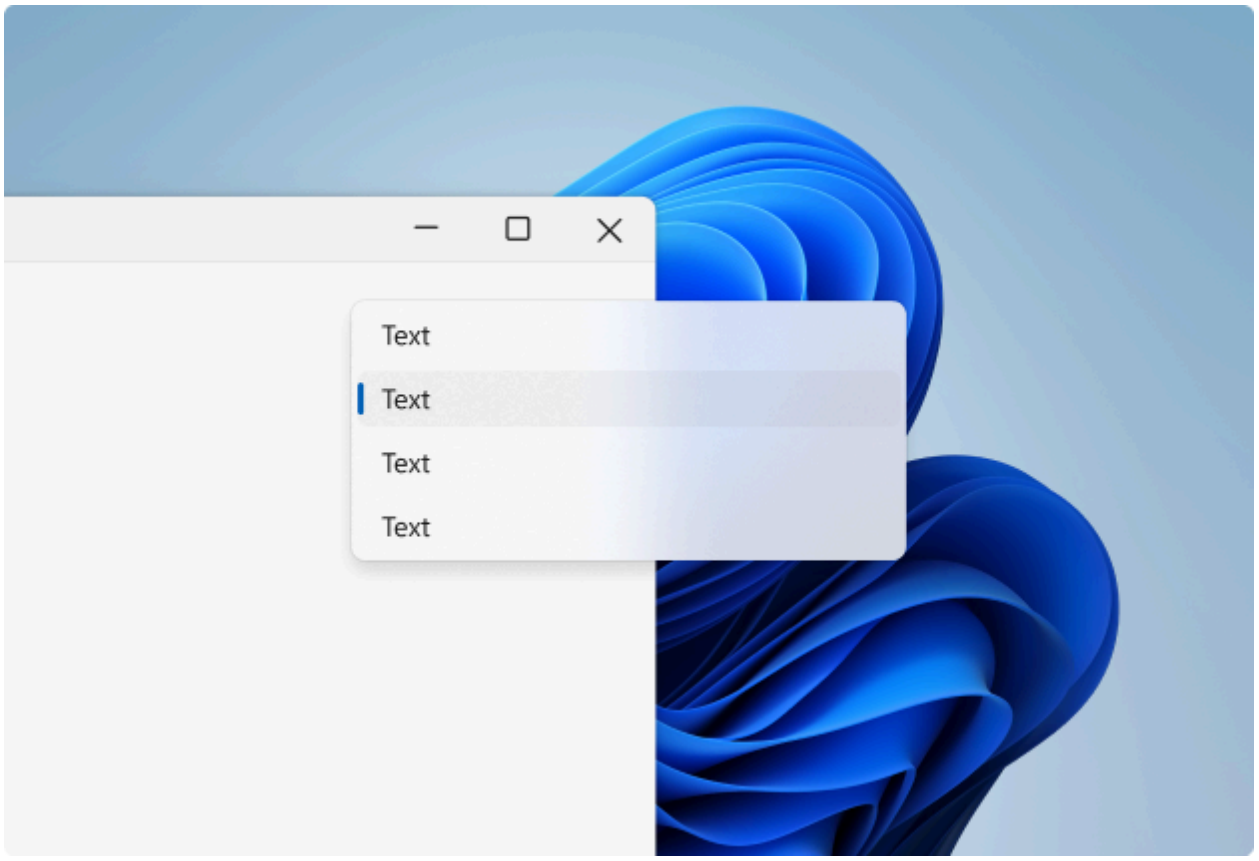


Elevation and layering

Elevation and layering is the concept of overlapping one surface with another, creating two or more visually distinguished areas within the same surface. Windows 11 uses elevation and layering as its foundation for app hierarchy.

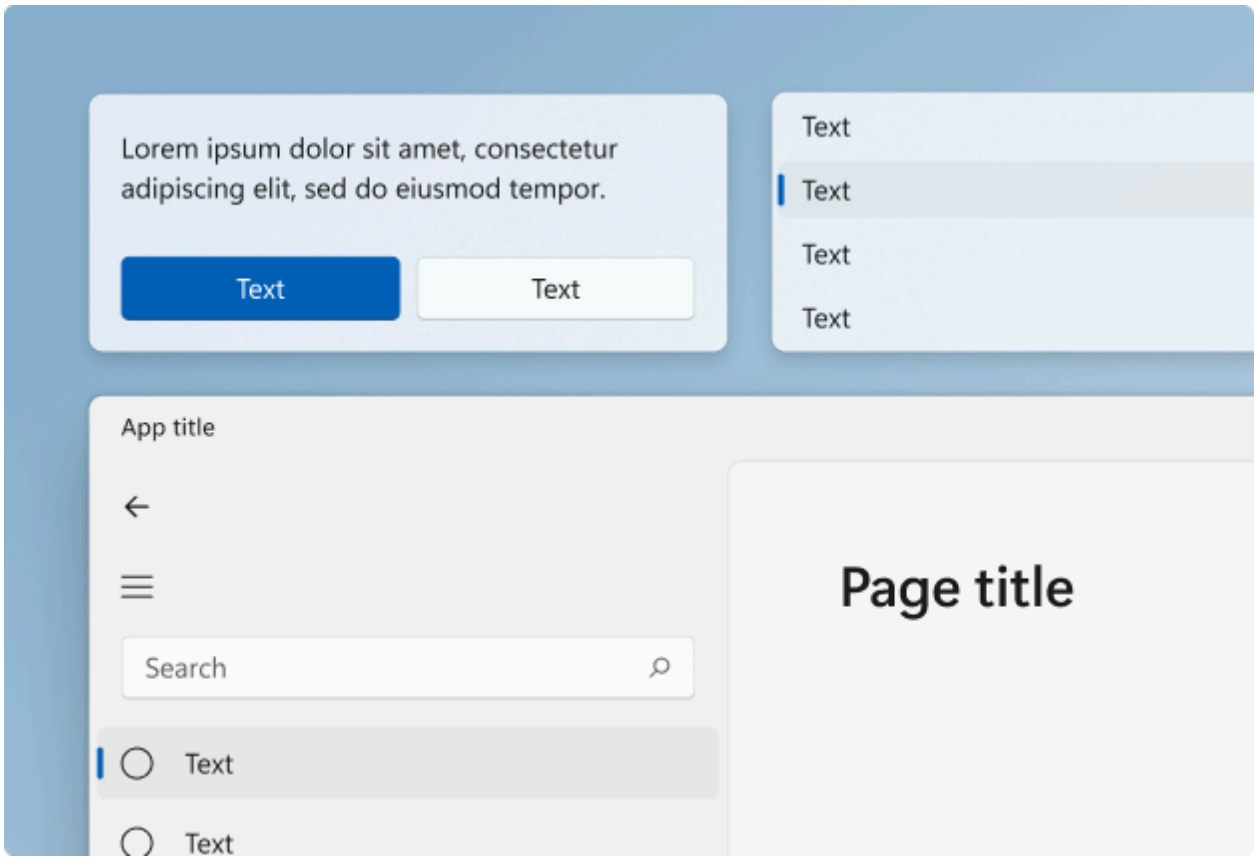
Iconography

Iconography is a set of visual images and symbols that help users understand and navigate your app. Windows 11 iconography has evolved in concert with our design language. Every glyph in our system icon font has been redesigned to embrace a softer geometry and more modern metaphors.



Materials

Materials are visual effects that make UI surfaces resemble real life artifacts. Windows 11 uses materials to keep the UI connected to its environment. Materials bring surfaces to life and help us distinguish between focused and unfocused applications.



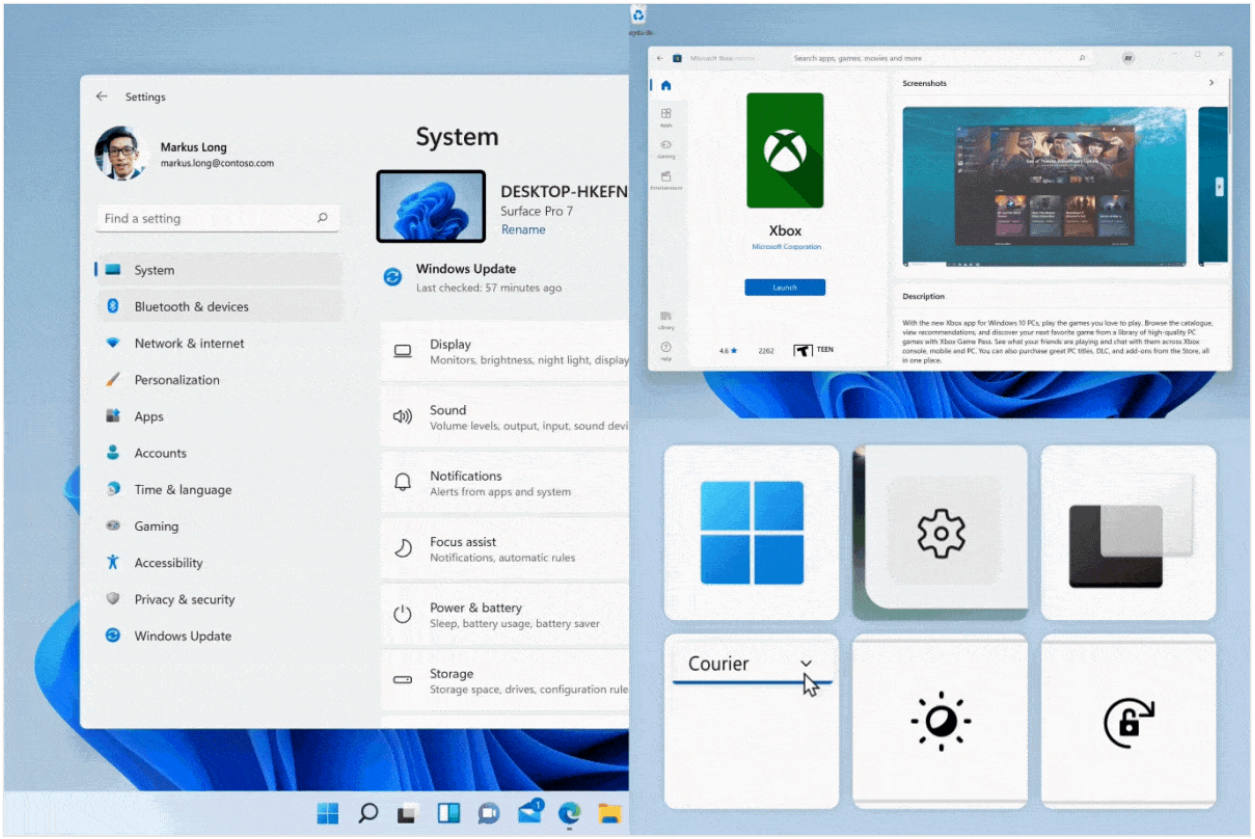
Shapes and geometry

Geometry describes the shape, size, and position of UI elements on screen. These fundamental design elements help experiences feel coherent across the entire design system. Windows 11 features updated geometry that creates a more approachable, engaging, and modern experience.

The quick brown fox jumped over the lazy dog.

Typography

As the visual representation of language, the main task of typography is to communicate information. The Windows 11 type system helps you create structure and hierarchy in your content in order to maximize legibility and readability in your UI.



Motion

Motion describes the way the interface animates and responds to user interaction. Motion in Windows is reactive, direct, and context appropriate. It provides feedback to user input and reinforces spatial paradigms that support way-finding.

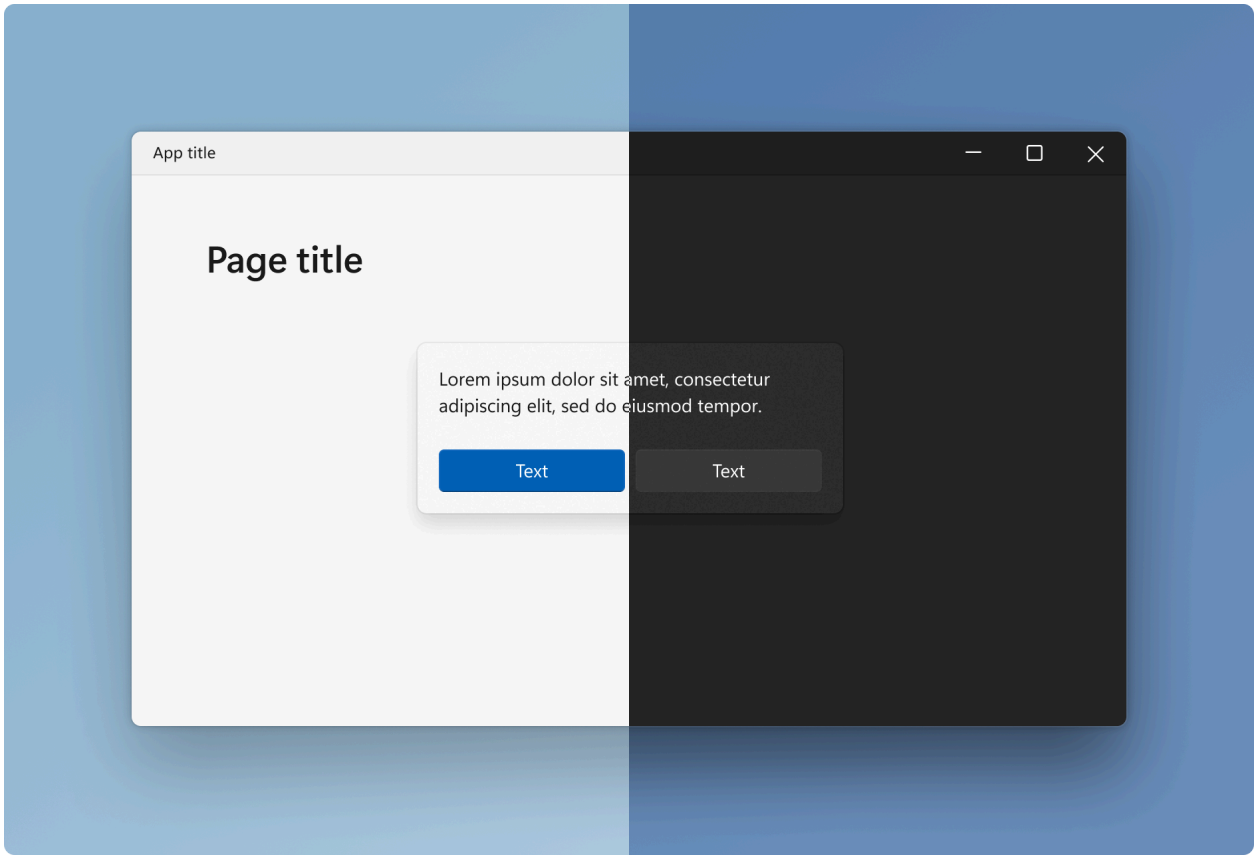
Color in Windows

Article • 11/05/2024

Windows employs color to help users focus on their tasks by indicating a visual hierarchy and structure between user interface elements. Color is context appropriate and used to provide a calming foundation, subtly enhancing user interactions and emphasizing significant items only when necessary.

> **Tip**
>
> This article describes how the Fluent Design language is applied to Windows apps. For more information, see Fluent Design - Color.

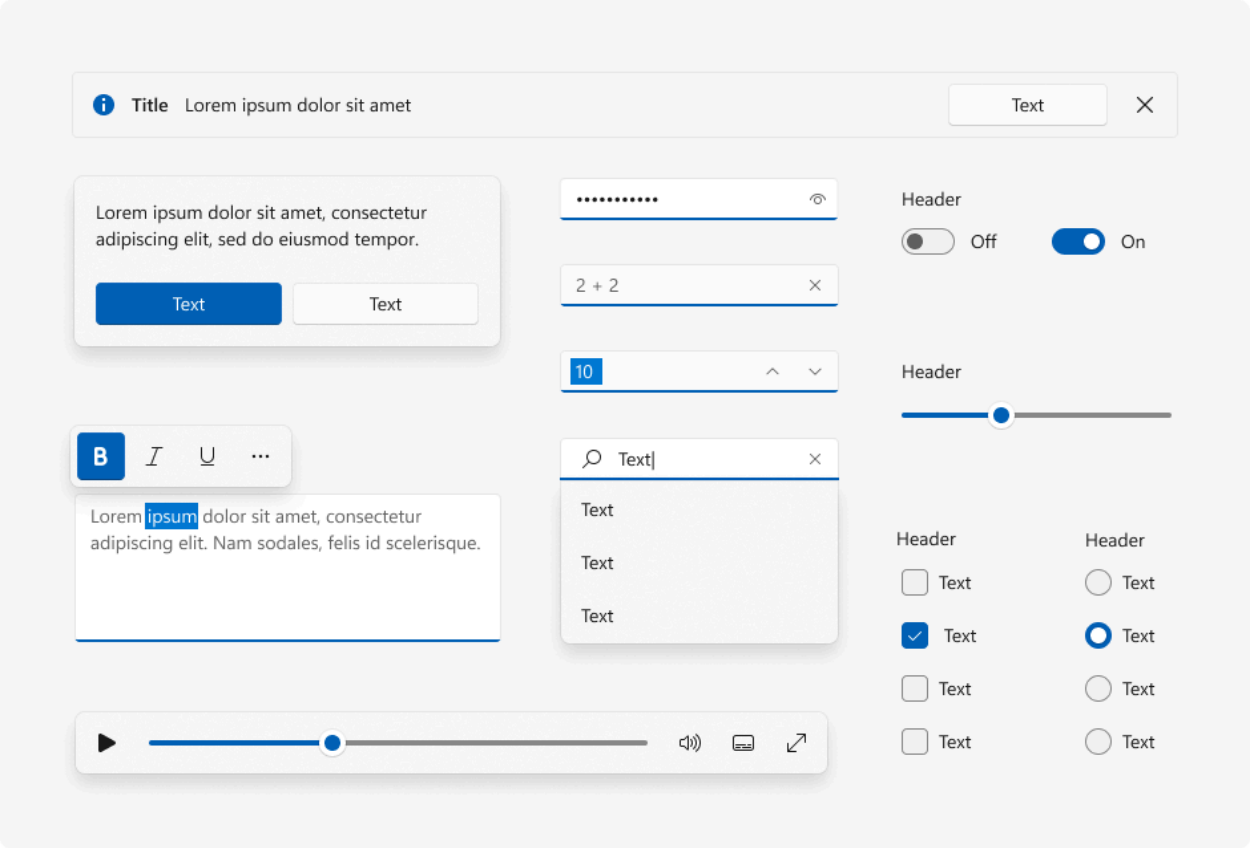
Color modes

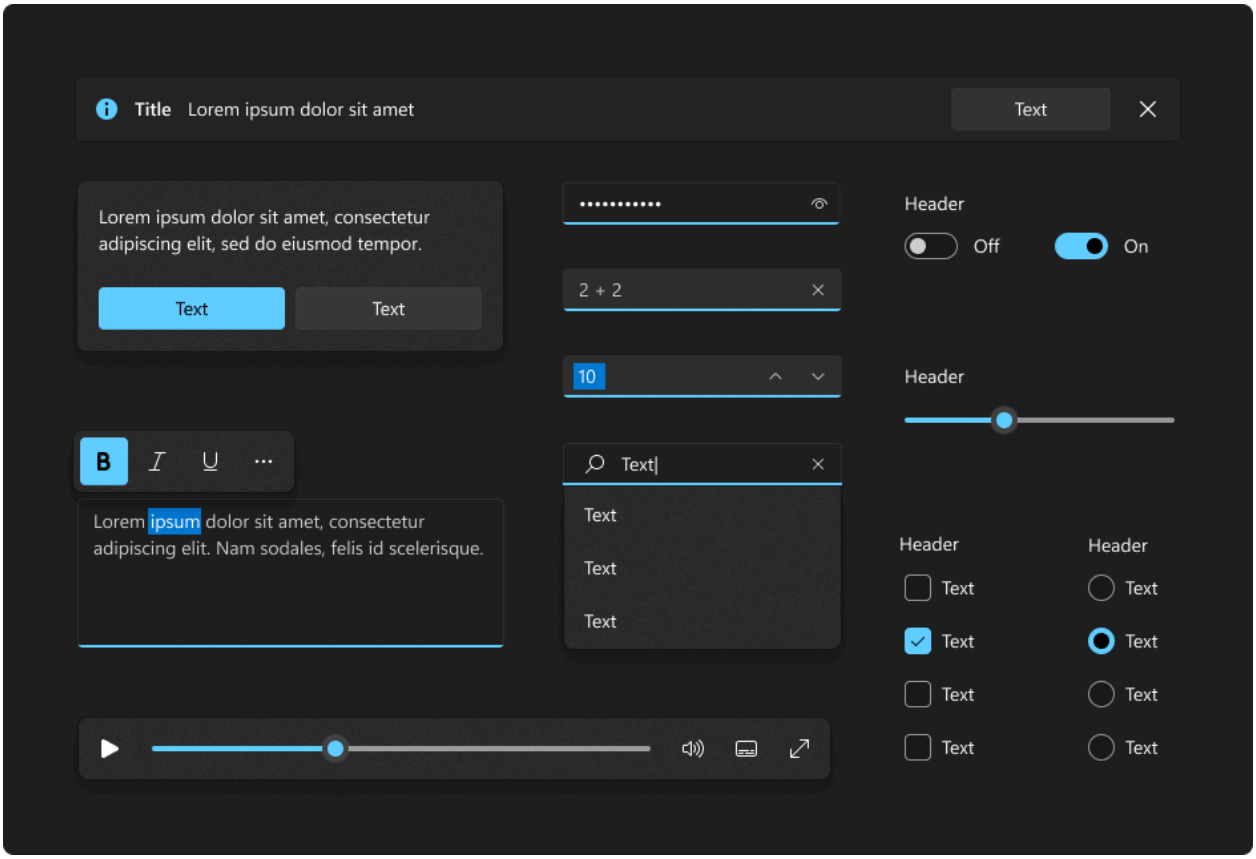


Windows supports two color modes, or themes: light and dark. Each mode consists of a set of neutral color values that are automatically adjusted to ensure optimal contrast.

In both light and dark color modes, darker colors indicate background surfaces of less importance. Important surfaces are highlighted with lighter and brighter colors. See layering & elevation for more information.

Accent color





Accent color is used to emphasize important elements in the user interface and to indicate the state of an interactive object or control. Accent color values are generated automatically and optimized for contrast in both light and dark modes. Accent colors

are used sparingly to highlight important elements and convey information about an interactive element's state.

Examples

Open the WinUI 3 Gallery app and see Color principles in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

Color in Windows apps

Color provides an intuitive way of communicating information to users in your app: it can be used to indicate interactivity, give feedback to user actions, and give your interface a sense of visual continuity.

In Windows apps, colors are primarily determined by accent color and theme. In this article, we'll discuss how you can use color in your app, and how to use accent color and theme resources to make your Windows app usable in any theme context.

Color principles

Use color meaningfully. When color is used sparingly to highlight important elements, it can help create a user interface that is fluid and intuitive.

Use color to indicate interactivity. It's a good idea to choose one color to indicate elements of your application that are interactive. For example, many web pages use blue text to denote a hyperlink.

Color is personal. In Windows, users can choose an accent color and a light or dark theme, which are reflected throughout their experience. You can choose how to incorporate the user's accent color and theme into your application, personalizing their experience.

Color is cultural. Consider how the colors you use will be interpreted by people from different cultures. For example, in some cultures the color blue is associated with virtue and protection, while in others it represents mourning.

Themes

Windows apps can use a light or dark application theme. The theme affects the colors of the app's background, text, icons, and common controls.

Light theme

Dark theme

By default, your Windows app's theme is the user's theme preference from Windows Settings or the device's default theme. However, you can set the theme specifically for your Windows app.

Changing the theme

You can change themes by changing the **RequestedTheme** property in your `App.xaml` file.

XAML

```
<Application
    x:Class="App9.App"
    xmlns="http://schemas.microsoft.com/winfx/2006/xaml/presentation"
    xmlns:x="http://schemas.microsoft.com/winfx/2006/xaml"
    xmlns:local="using:App9"
    RequestedTheme="Dark">
</Application>
```

Removing the **RequestedTheme** property means that your application will use the user's system settings.

Users can also select the high contrast theme, which uses a small palette of contrasting colors that makes the interface easier to see. In that case, the system will override your RequestedTheme.

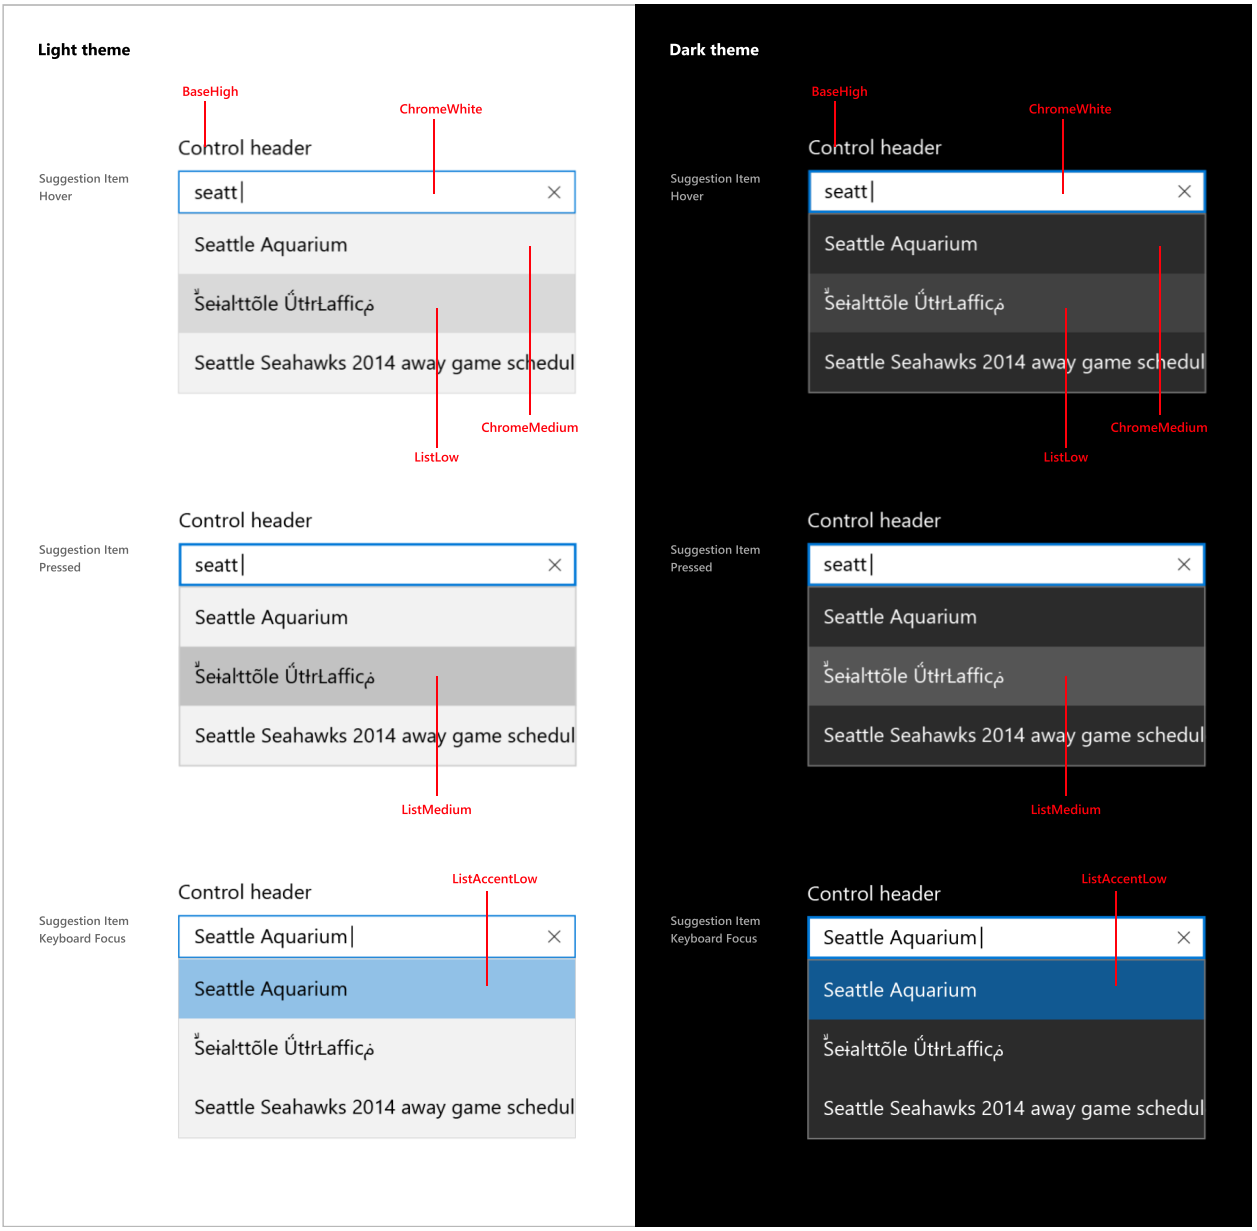
Testing themes

If you don't request a theme for your app, make sure to test your app in both light and dark themes to ensure that your app will be legible in all conditions.

Theme brushes

Common controls automatically use theme brushes to adjust contrast for light and dark themes.

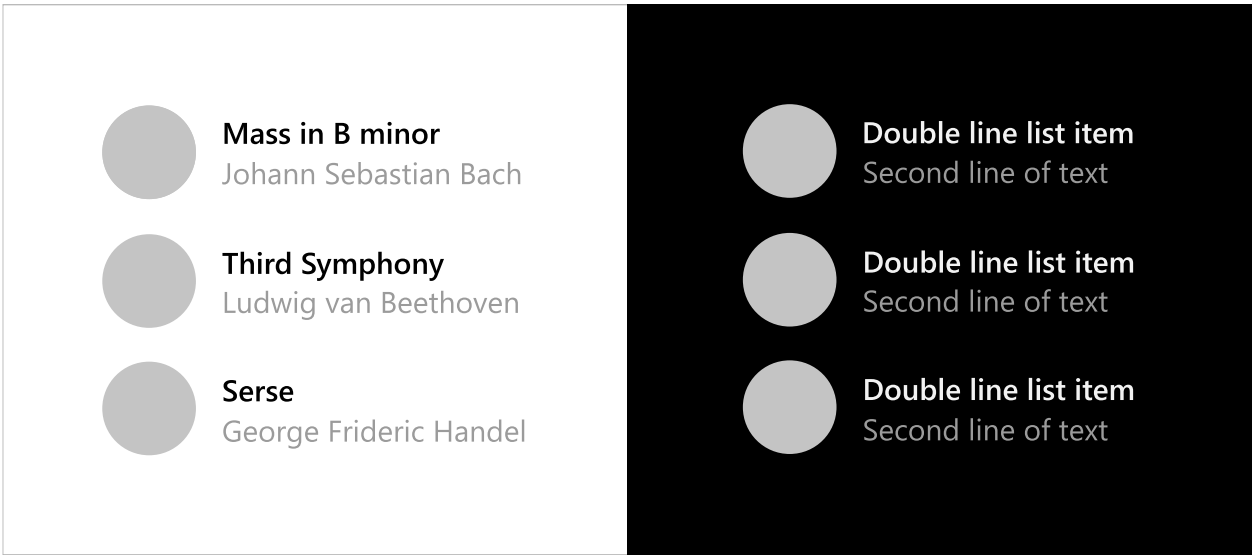
For example, here's an illustration of how the AutoSuggestBox uses theme brushes:



Using theme brushes

When creating templates for custom controls, use theme brushes rather than hard code color values. This way, your app can easily adapt to any theme.

For example, these item templates for ListView demonstrate how to use theme brushes in a custom template.



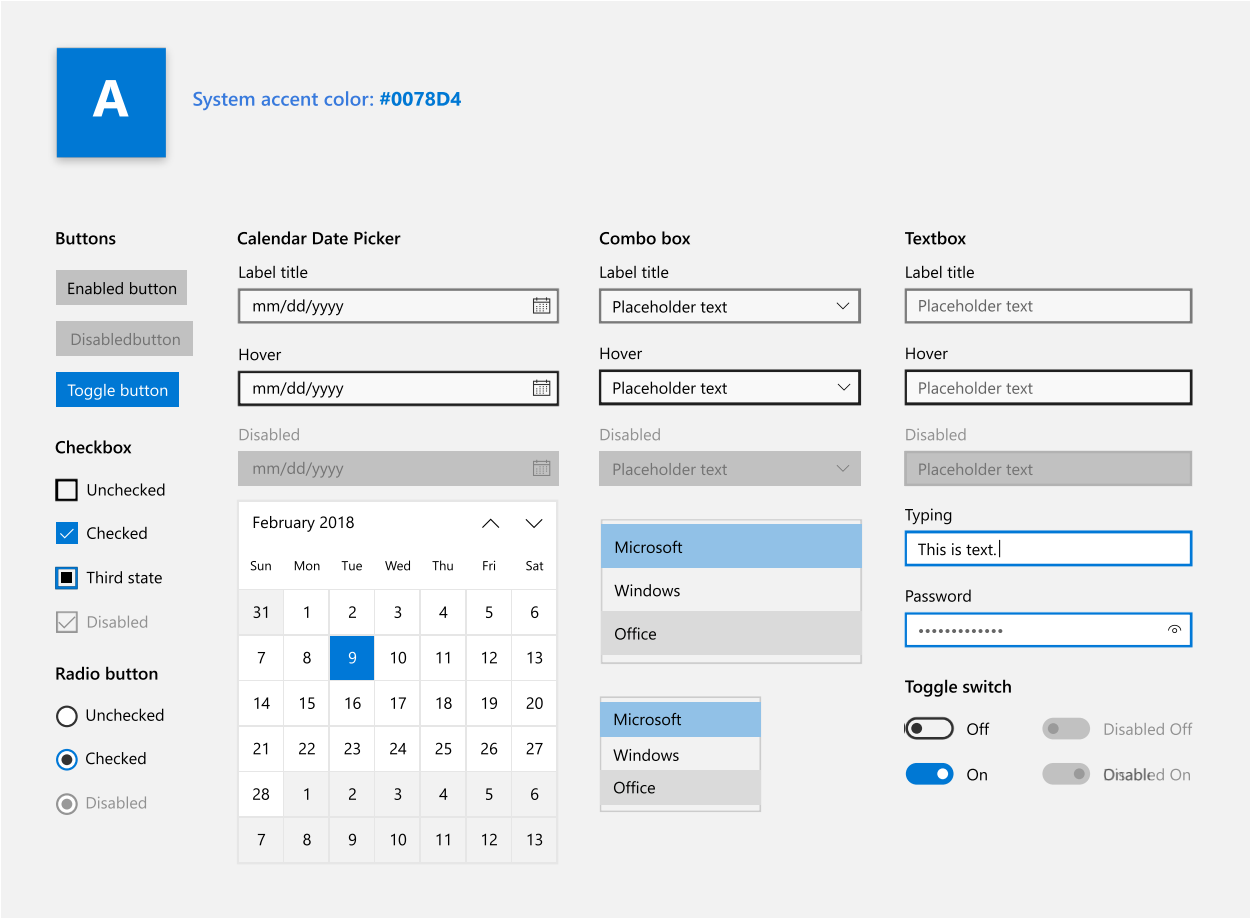
XAML

```
<ListView ItemsSource="{x:Bind ViewModel.Recordings}">
    <ListView.ItemTemplate>
        <DataTemplate x:Name="DoubleLineDataTemplate"
x:DataType="local:Recording">
            <StackPanel Orientation="Horizontal" Height="64"
AutomationProperties.Name="{x:Bind CompositionName}">
                <Ellipse Height="48" Width="48" VerticalAlignment="Center">
                    <Ellipse.Fill>
                        <ImageBrush ImageSource="Placeholder.png"/>
                    </Ellipse.Fill>
                </Ellipse>
                <StackPanel Orientation="Vertical"
VerticalAlignment="Center" Margin="12,0,0,0">
                    <TextBlock Text="{x:Bind CompositionName}" Style="
{ThemeResource BodyStrongTextBlockStyle}" Foreground="{ThemeResource
TextFillColorPrimaryBrush}" />
                    <TextBlock Text="{x:Bind ArtistName}" Style="
{ThemeResource BodyTextBlockStyle}" Foreground="{ThemeResource
TextFillColorTertiaryBrush}"/>
                </StackPanel>
            </StackPanel>
        </DataTemplate>
    </ListView.ItemTemplate>
</ListView>
```

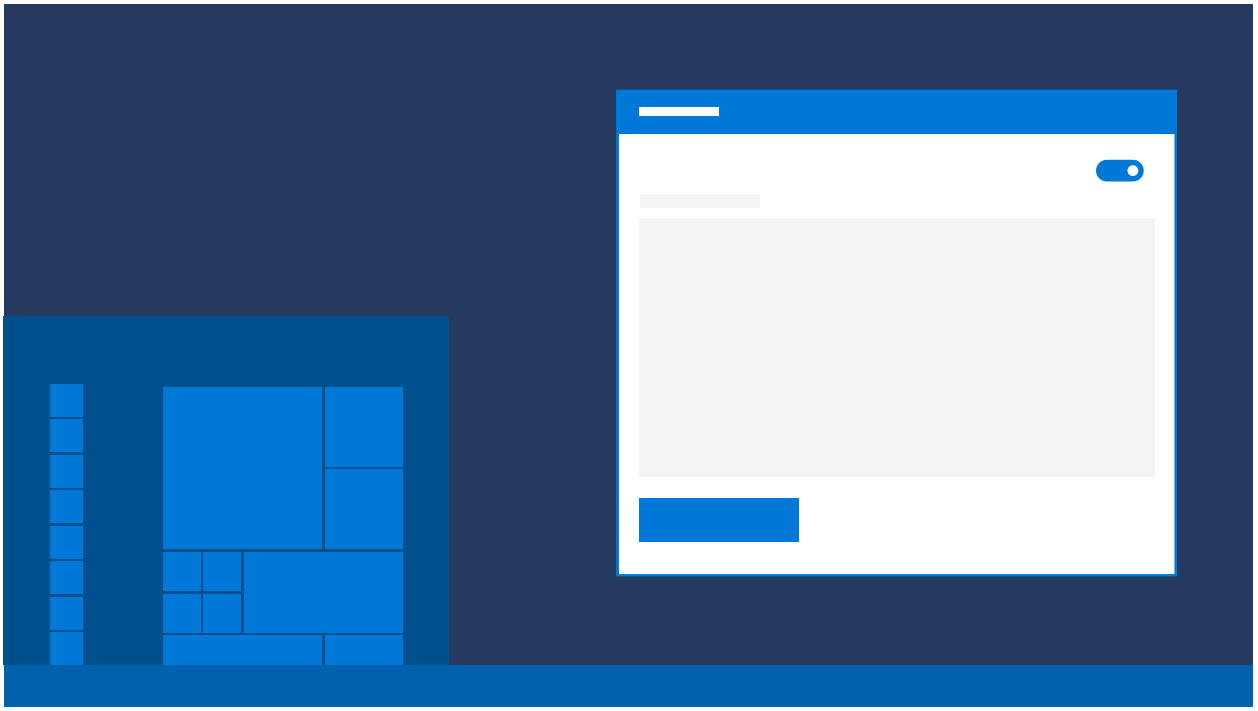
For more information about how to use theme brushes in your app, see Theme Resources.

Accent colors

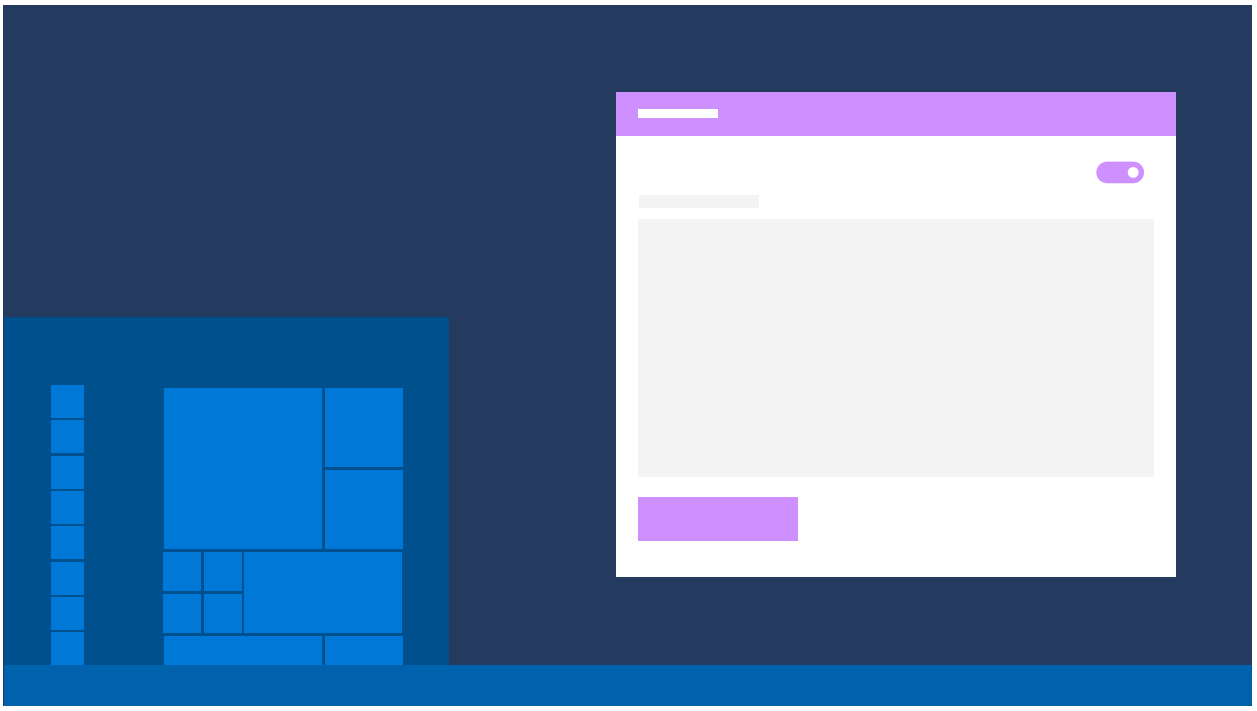
Common controls use an accent color to convey state information. By default, the accent color is the `SystemAccentColor` that users select in their Settings. However, you can also customize your app's accent color to reflect your brand.



A User-selected system accent color



C **Custom accent color**



Overriding the accent color

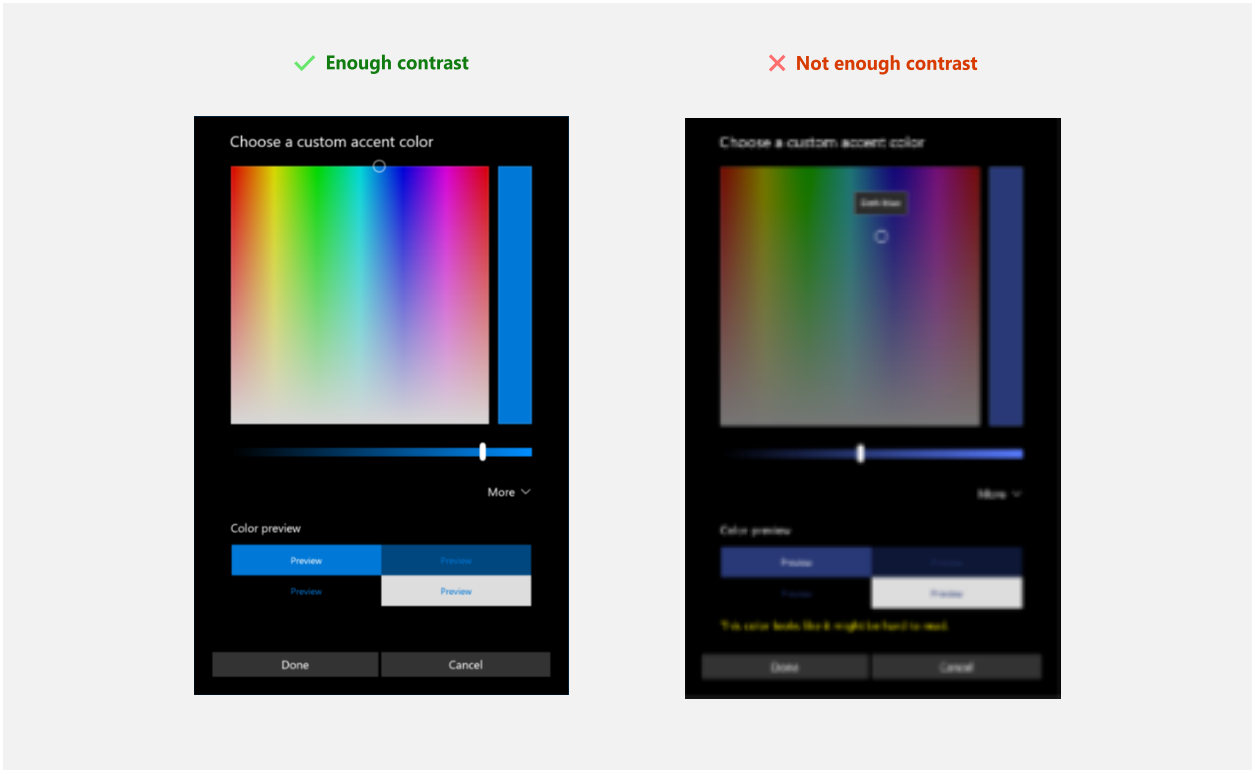
To change your app's accent color, place the following code in `app.xaml`.

XAML

```
<Application.Resources>
    <ResourceDictionary>
        <Color x:Key="SystemAccentColor">#107C10</Color>
    </ResourceDictionary>
</Application.Resources>
```

Choosing an accent color

If you select a custom accent color for your app, please make sure that text and backgrounds that use the accent color have sufficient contrast for optimal readability. To test contrast, you can use the color picker tool in Windows Settings, or you can use these online contrast tools.



Accent color palette

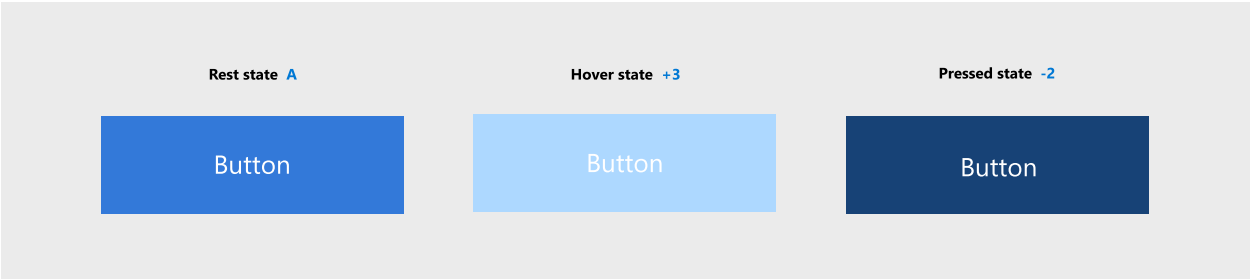
An accent color algorithm in the Windows shell generates light and dark shades of the accent color.

These shades can be accessed as theme resources:

- `SystemAccentColorLight3`
- `SystemAccentColorLight2`
- `SystemAccentColorLight1`
- `SystemAccentColorDark1`
- `SystemAccentColorDark2`
- `SystemAccentColorDark3`

You can also access the accent color palette programmatically with the **UISettings.GetColorValue** method and **UIColorType** enum.

You can use the accent color palette for color theming in your app. Below is an example of how you can use the accent color palette on a button.



XAML

```
<Page.Resources>
    <ResourceDictionary>
        <ResourceDictionary.ThemeDictionaries>
            <ResourceDictionary x:Key="Light">
                <SolidColorBrush x:Key="ButtonBackground" Color="
{ThemeResource SystemAccentColor}"/>
                <SolidColorBrush x:Key="ButtonBackgroundPointerOver" Color="
{ThemeResource SystemAccentColorLight1}"/>
                <SolidColorBrush x:Key="ButtonBackgroundPressed" Color="
{ThemeResource SystemAccentColorDark1}"/>
            </ResourceDictionary>
        </ResourceDictionary.ThemeDictionaries>
    </ResourceDictionary>
</Page.Resources>

<Button Content="Button"></Button>
```

When using colored text on a colored background, make sure there is enough contrast between text and background. By default, hyperlink or hypertext will use the accent color. If you apply variations of the accent color to the background, you should use a variation of the original accent color to optimize the contrast of colored text on a colored background.

The chart below illustrates an example of the various light/dark shades of accent color, and how colored type can be applied on a colored surface.

For more information about styling controls, see XAML styles.

Color API

There are several APIs that can be used to add color to your application. First, the **Colors** class, which implements a large list of predefined colors. These can be accessed automatically with XAML properties. In the example below, we create a button and set the background and foreground color properties to members of the **Colors** class.

XAML

```
<Button Background="MediumSlateBlue" Foreground="White">Button text</Button>
```

You can create your own colors from RGB or hex values using the **Color** struct in XAML.

XAML

```
<Color x:Key="LightBlue">#FF36C0FF</Color>
```

You can also create the same color in code by using the **FromArgb** method.

C#

```
Color LightBlue = Color.FromArgb(255,54,192,255);
```

C++/WinRT

```
Windows::UI::Color LightBlue =
Windows::UI::ColorHelper::FromArgb(255,54,192,255);
```

The letters "Argb" stands for Alpha (opacity), Red, Green, and Blue, which are the four components of a color. Each argument can range from 0 to 255. You can choose to omit the first value, which will give you a default opacity of 255, or 100% opaque.

> **Note**
>
> If you're using C++, you must create colors by using the ColorHelper class.

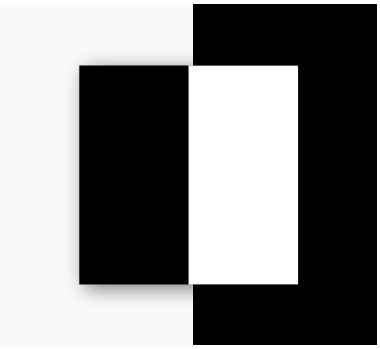
The most common use for a **Color** is as an argument for a SolidColorBrush, which can be used to paint UI elements a single solid color. These brushes are generally defined in a ResourceDictionary, so they can be reused for multiple elements.

XAML

```
<ResourceDictionary>
    <SolidColorBrush x:Key="ButtonBackgroundBrush" Color="#FFFF4F67"/>
    <SolidColorBrush x:Key="ButtonForegroundBrush" Color="White"/>
</ResourceDictionary>
```

For more information on how to use brushes, see XAML brushes.

Usability



Contrast

Make sure that elements and images have sufficient contrast to differentiate between them, regardless of the accent color or theme.

When considering what colors to use in your application, accessibility should be a primary concern. Use the guidance below to make sure your application is accessible to as many users as possible.

Lighting

Be aware that variation in ambient lighting can affect the usability of your app. For example, a page with a black background might unreadable outside due to screen glare, while a page with a white background might be painful to look at in a dark room.

Colorblindness

Be aware of how colorblindness could affect the usability of your application. For example, a user with red-green colorblindness will have difficulty distinguishing red and green elements from each other. About **8 percent of men** and **0.5 percent of women** are red-green colorblind, so avoid using these color combinations as the sole differentiator between application elements.

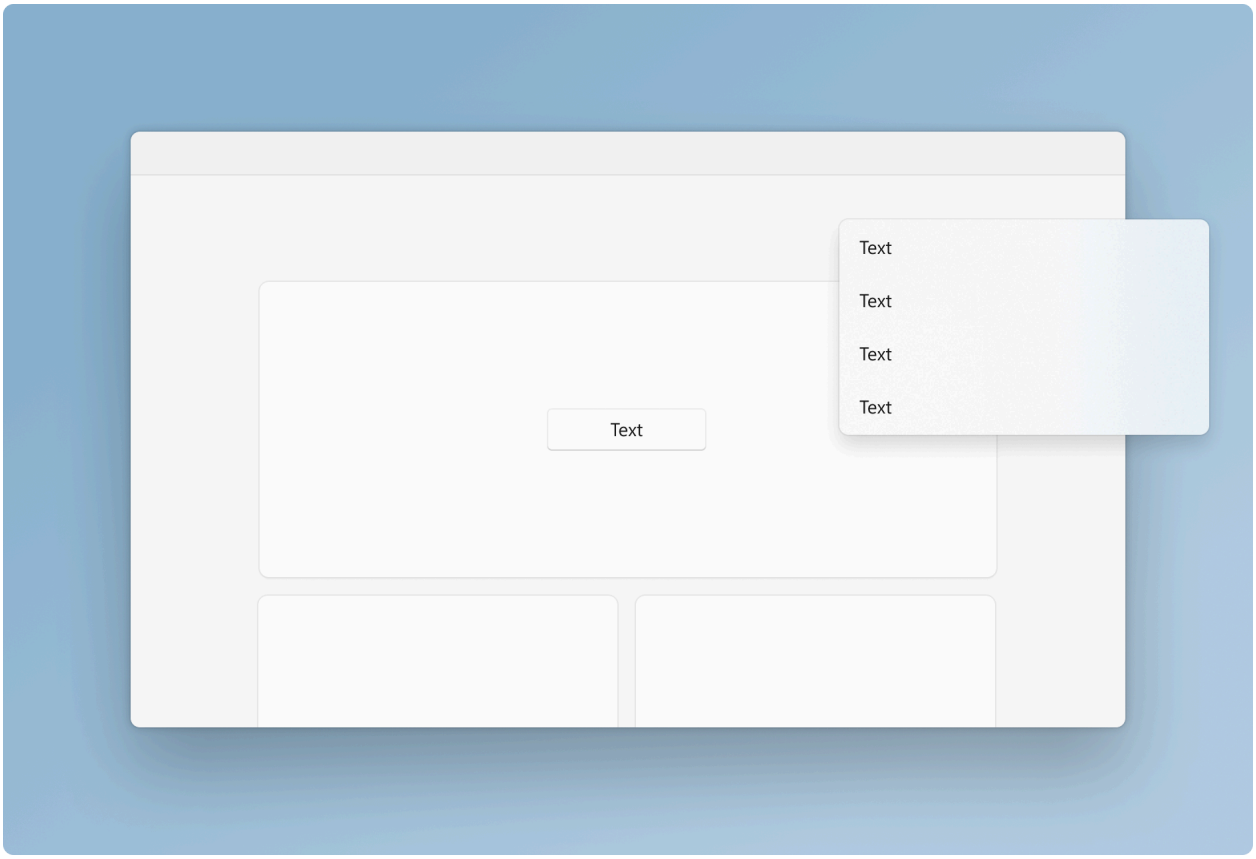
Elevation in Windows

Article • 11/05/2024

Windows 11 uses layering and elevation as its foundation for app hierarchy. Hierarchy communicates important information about how to navigate within an app while keeping the user's attention focused on the most important content. Layering and elevation are powerful visual cues that modernize experiences and help them feel coherent within Windows.

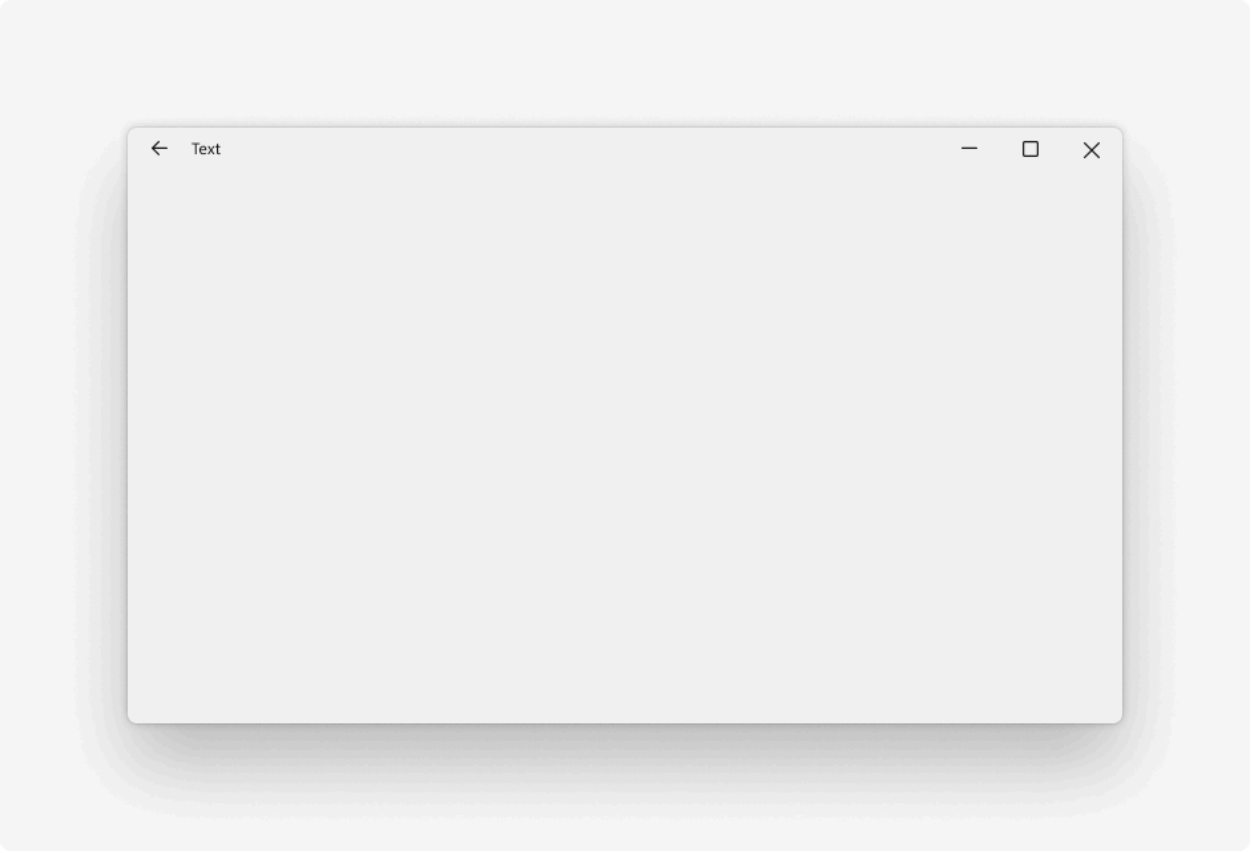
> **Tip**
>
> This article describes how the Fluent Design language is applied to Windows apps. For more information, see Fluent Design - Elevation.

Elevation

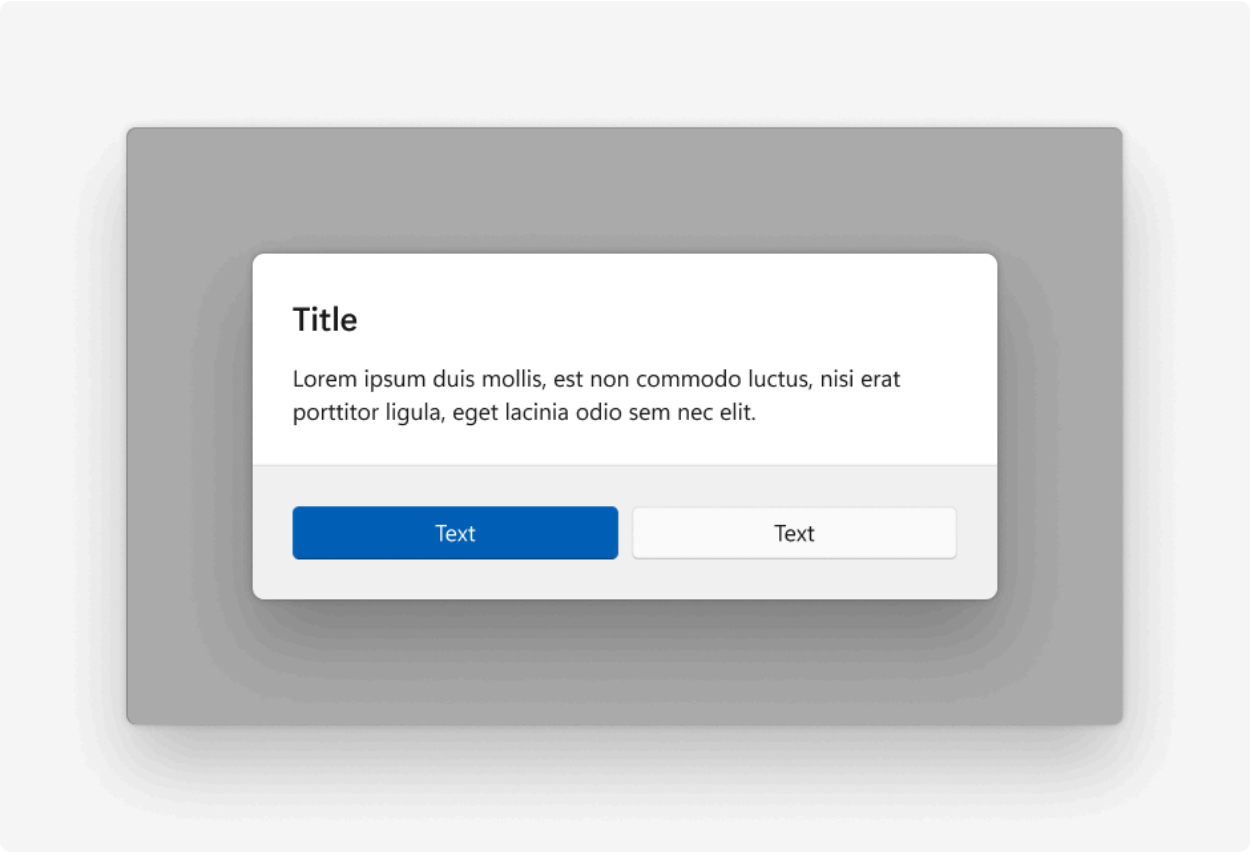


Elevation is the depth component of the spatial relationship one surface has to another with respect to their position on the desktop. When two or more objects occupy the same location on the screen, only the object with the highest elevation will be rendered at that location.

Shadows and contour (outlines) are used on controls and surfaces to subtly communicate an object's elevation, and to help draw focus where needed within an experience. Windows 11 uses the following values to express elevation with shadow and contour.



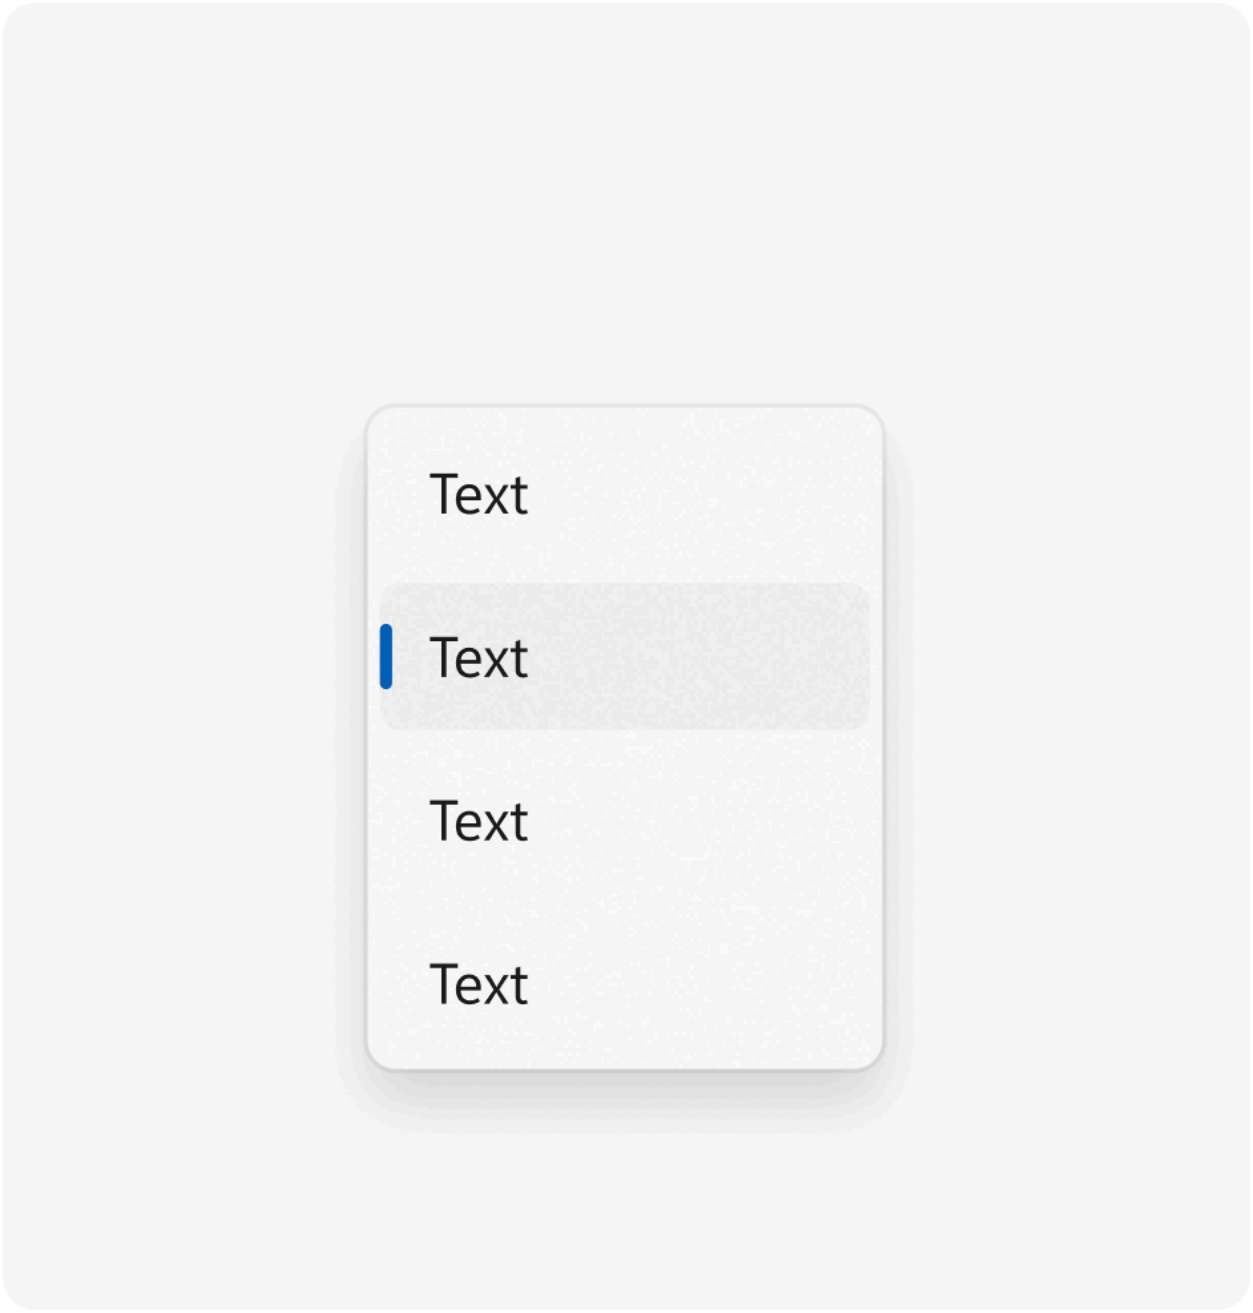
Window
Elevation value: 128
Stroke width: 1



Dialog

Elevation value: 128

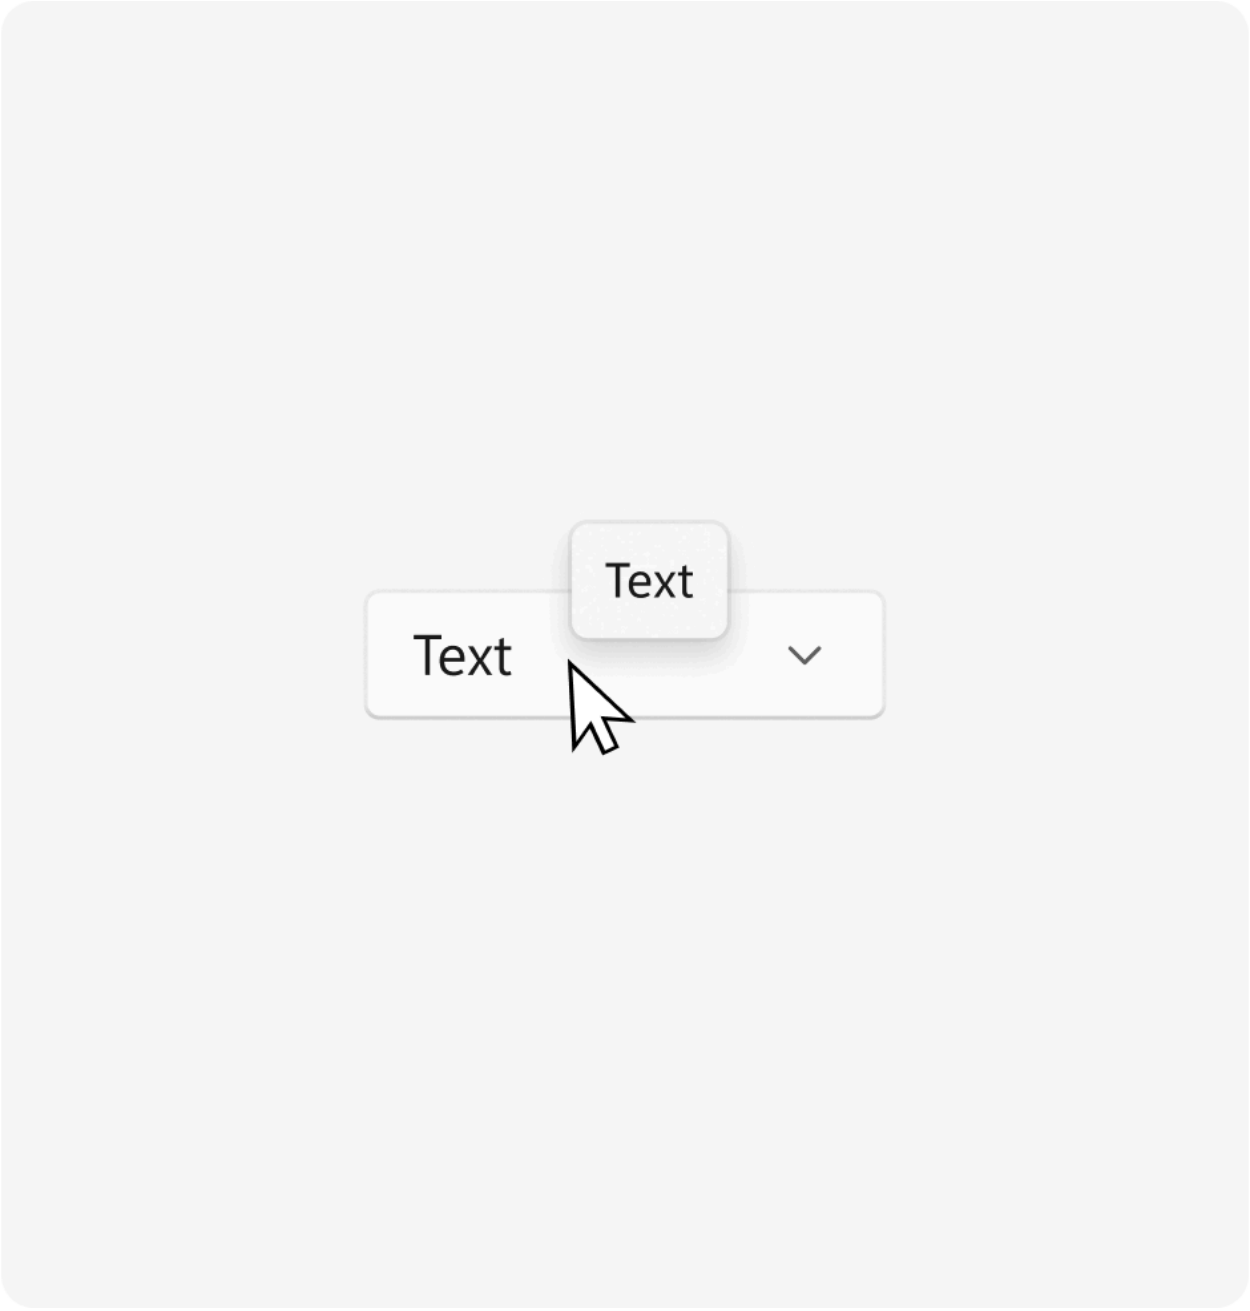
Stroke width: 1



Flyout

Elevation value: 32

Stroke width: 1



Tooltip

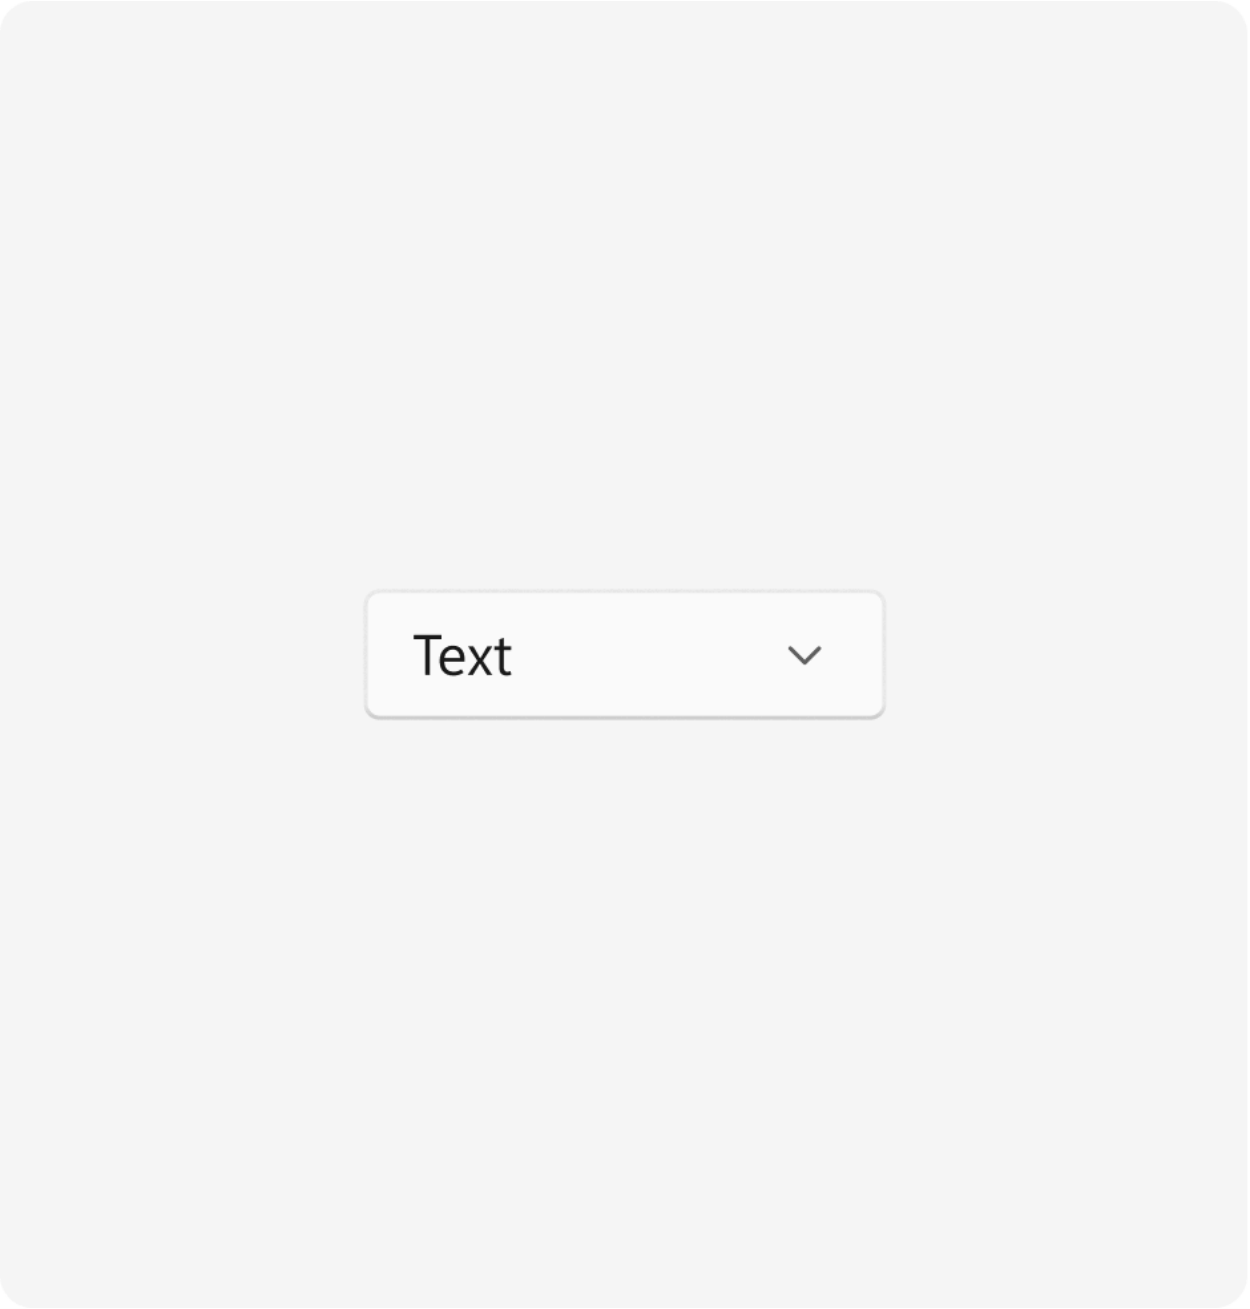
Elevation value: 16

Stroke width: 1

Card

Elevation value: 8

Stroke width: 1



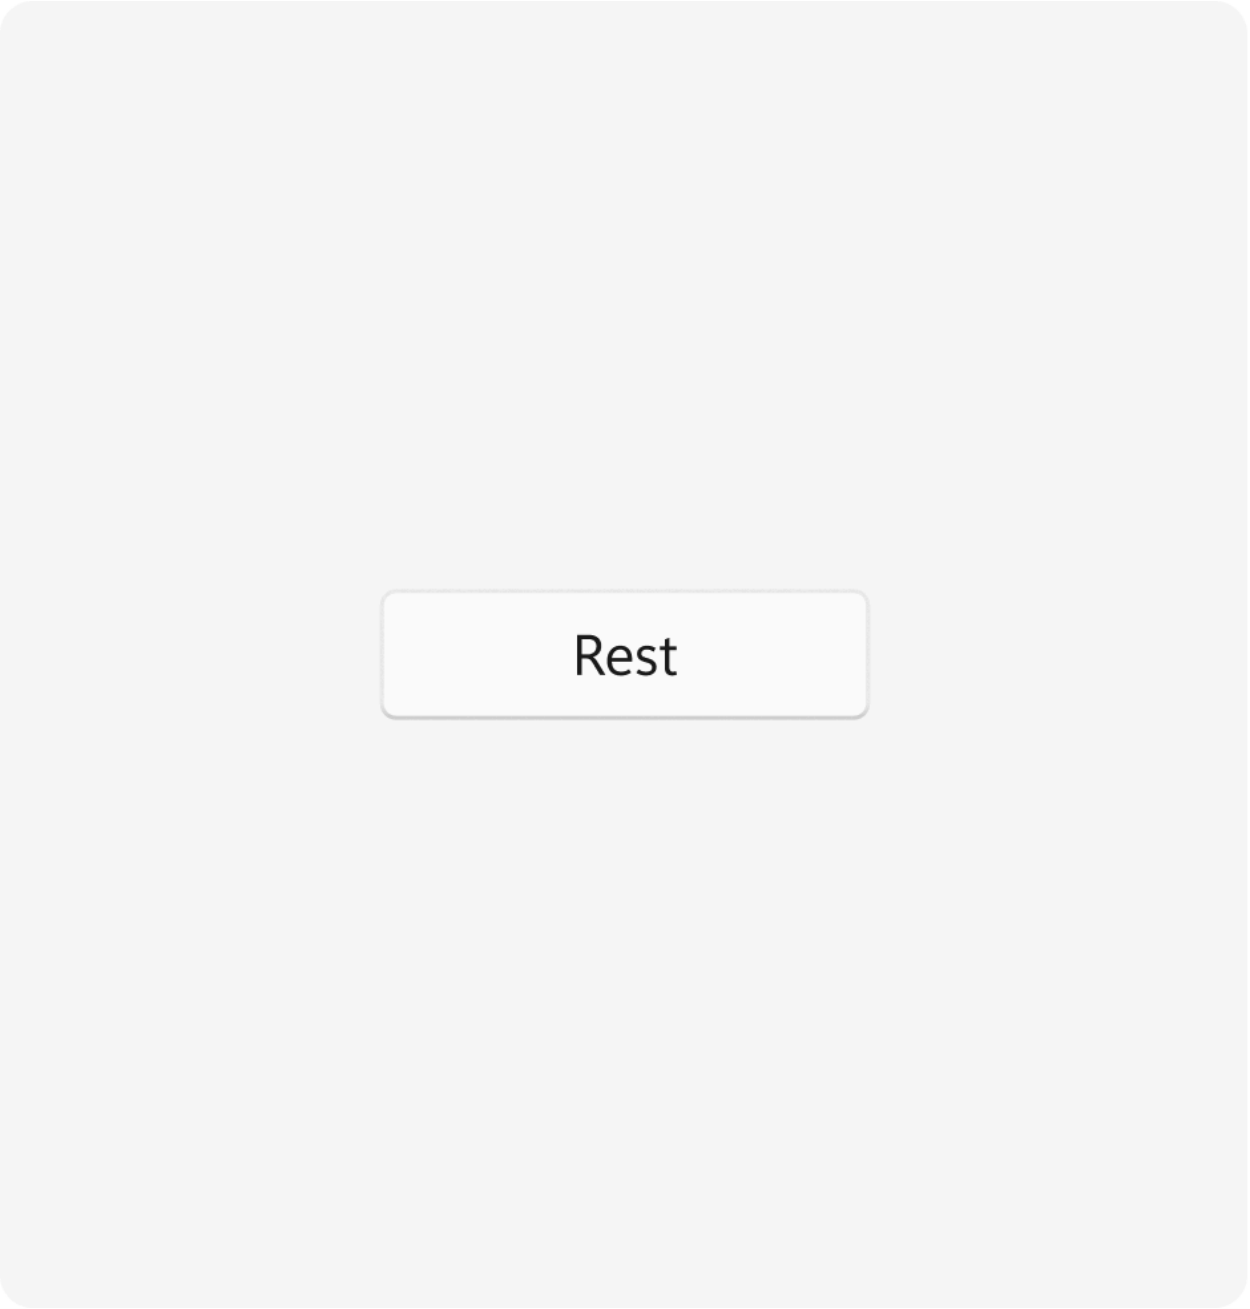
Control

Elevation value: 2

Stroke width: 1

Layer
Elevation value: 1
Stroke width: 1

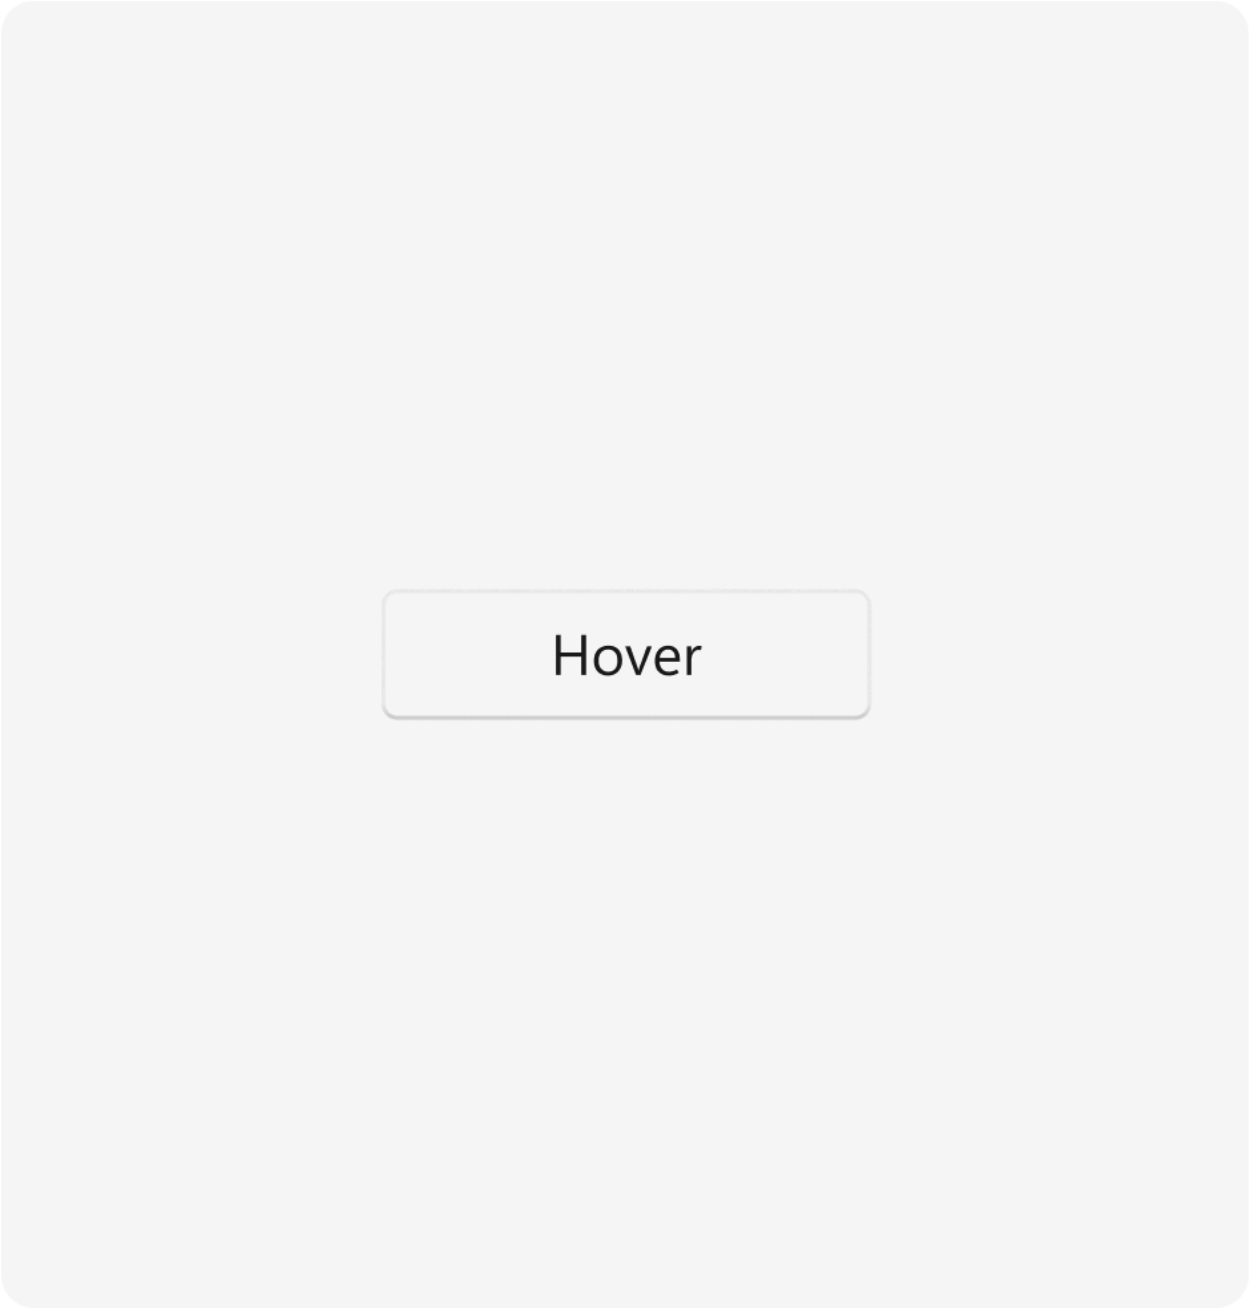
Controls in Windows 11 vary their elevation and contour to indicate state. The intensity of the rendered shadow changes depending on the theme at parity of value.



Rest

Elevation value: 2

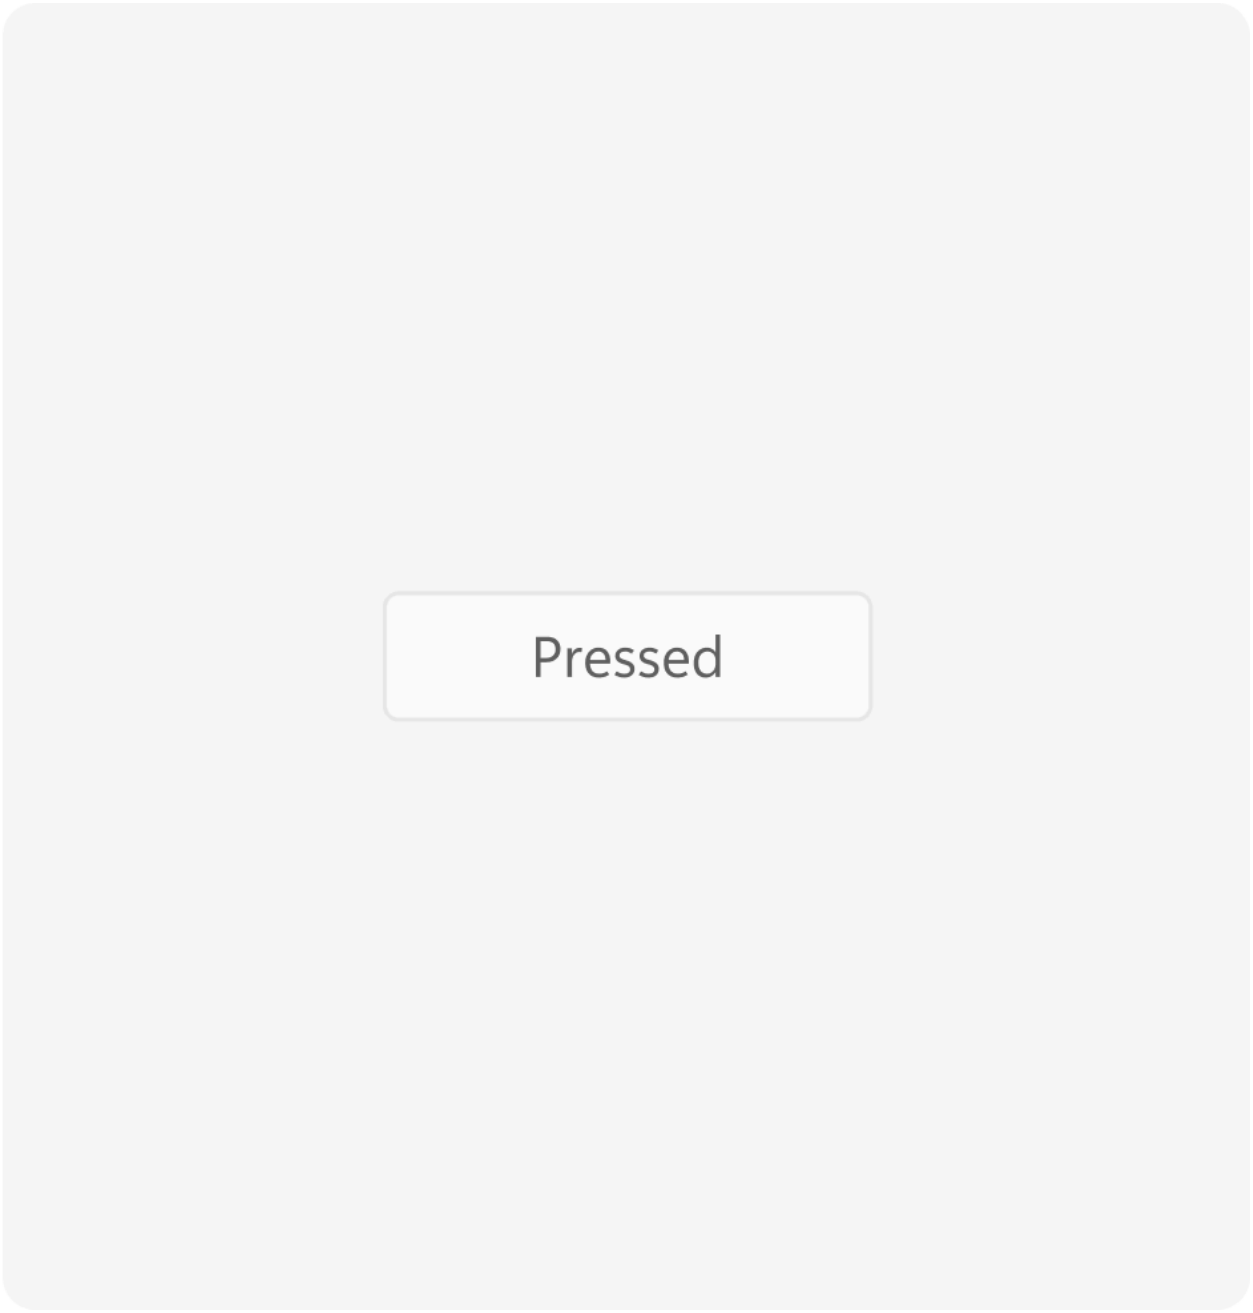
Stroke width: 1



Hover

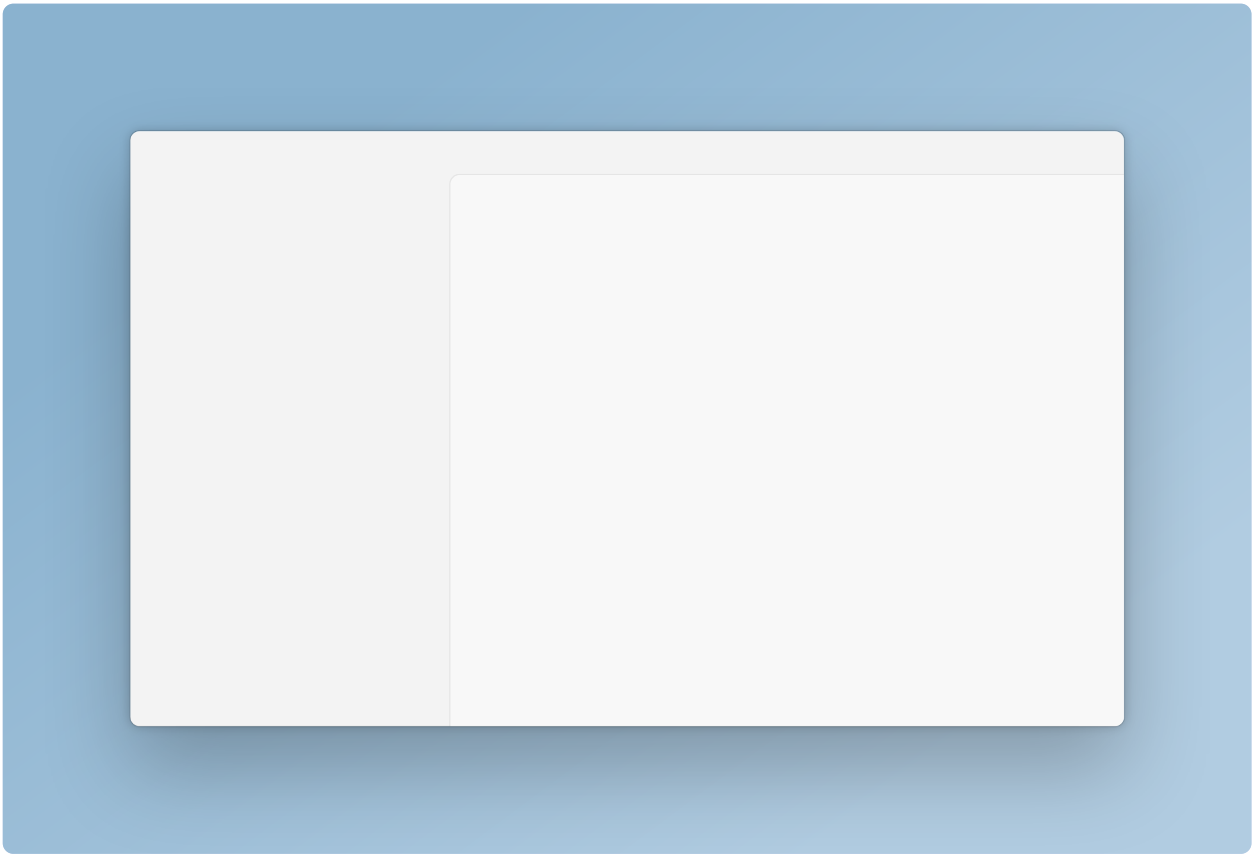
Elevation value: 2

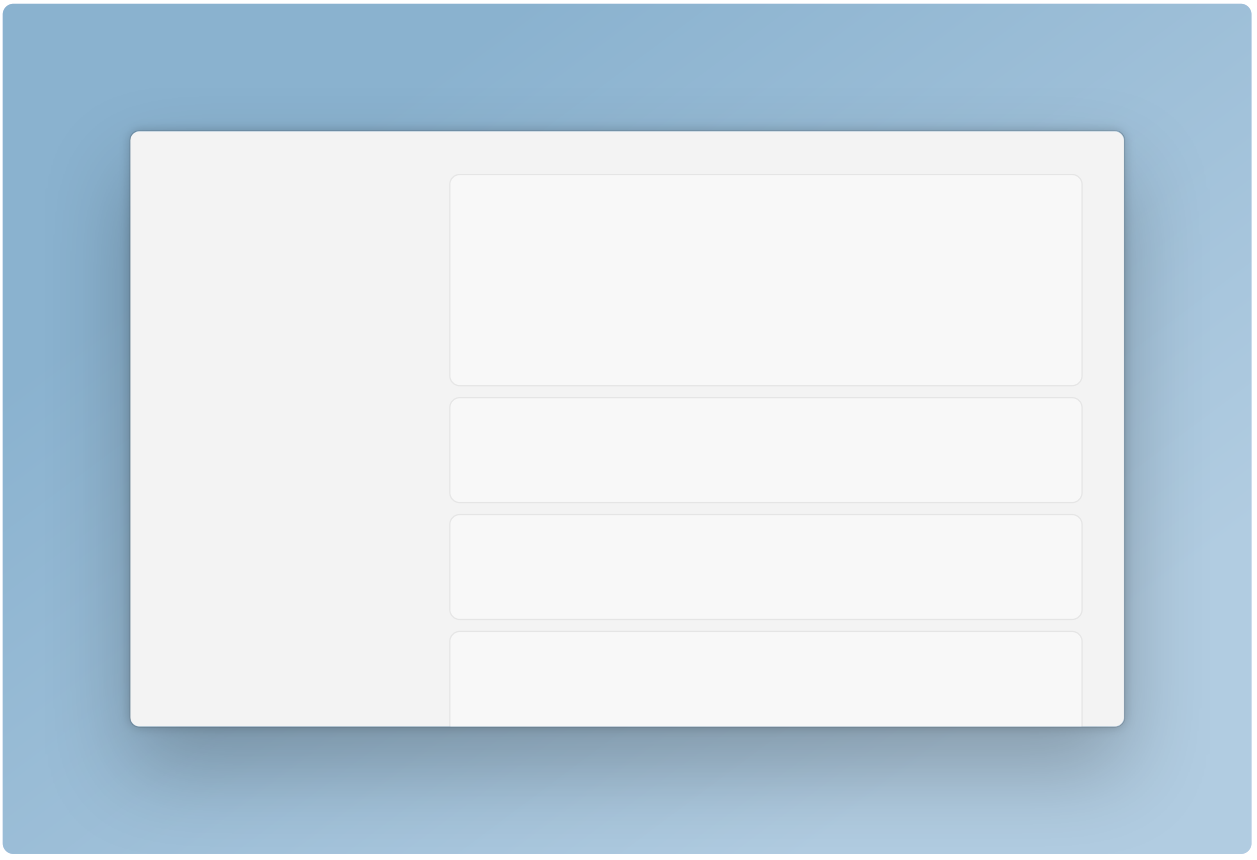
Stroke width: 1



Pressed
Elevation value: 1
Stroke width: 1

Layering





Layering is the concept of overlapping one surface with another, creating two or more visually distinguished areas within the same application.

Note

Layering in Windows is tightly coupled with the use of materials. Please reference the **materials section** for specific guidance on how those are applied.

Windows 11 uses a two-layer system for applications. These two layers create hierarchy and provide clarity, keeping users focused on what's most important.

- The **base** layer is an app's foundation. It is the bottommost layer of every app, and contains controls related to app menus, commands, and navigation.
- The **content** layer focuses the user on the app's central experience. The content layer may be on contiguous element, or separated into cards that segment content.

Z-depth and shadow

Article • 09/26/2024

Creating a visual hierarchy of elements in your UI makes the UI easy to scan and conveys what is important to focus on. Elevation, the act of bringing select elements of your UI forward, is often used to achieve such a hierarchy in software. This article discusses how to create elevation in a Windows app by using z-depth and shadow.

Z-depth is a term used amongst 3D app creators to denote the distance between two surfaces along the z-axis. It illustrates how close an object is to the viewer. Think of it as a similar concept to x/y coordinates, but in the z direction.

Windows apps use shadows to express depth and add visual hierarchy. To achieve this, the z-axis provides an easy coding path. However, the shadows are emulated; they are not displayed in the true 3D sense. This is so that we can achieve the feeling of depth without sacrificing the performance of your app's UI.

Why use z-depth?

In the physical world, we tend to focus on objects that are closer to us. We can apply this spatial instinct to digital UI as well. For example, if you bring an element closer to the user, then the user will instinctively focus on the element. By moving UI elements closer on the z-axis, you can establish visual hierarchy between objects, helping users complete tasks naturally and efficiently in your app.

What is shadow?

Shadow is one way a user perceives elevation. Light above an elevated object creates a shadow on the surface below. The higher the object, the larger and softer the shadow becomes. Elevated objects in your UI don't need to have shadows, but they help create the appearance of elevation.

In Windows apps, shadows should be used in a purposeful rather than aesthetic manner. Using too many shadows will decrease or eliminate the ability of the shadow to focus the user.

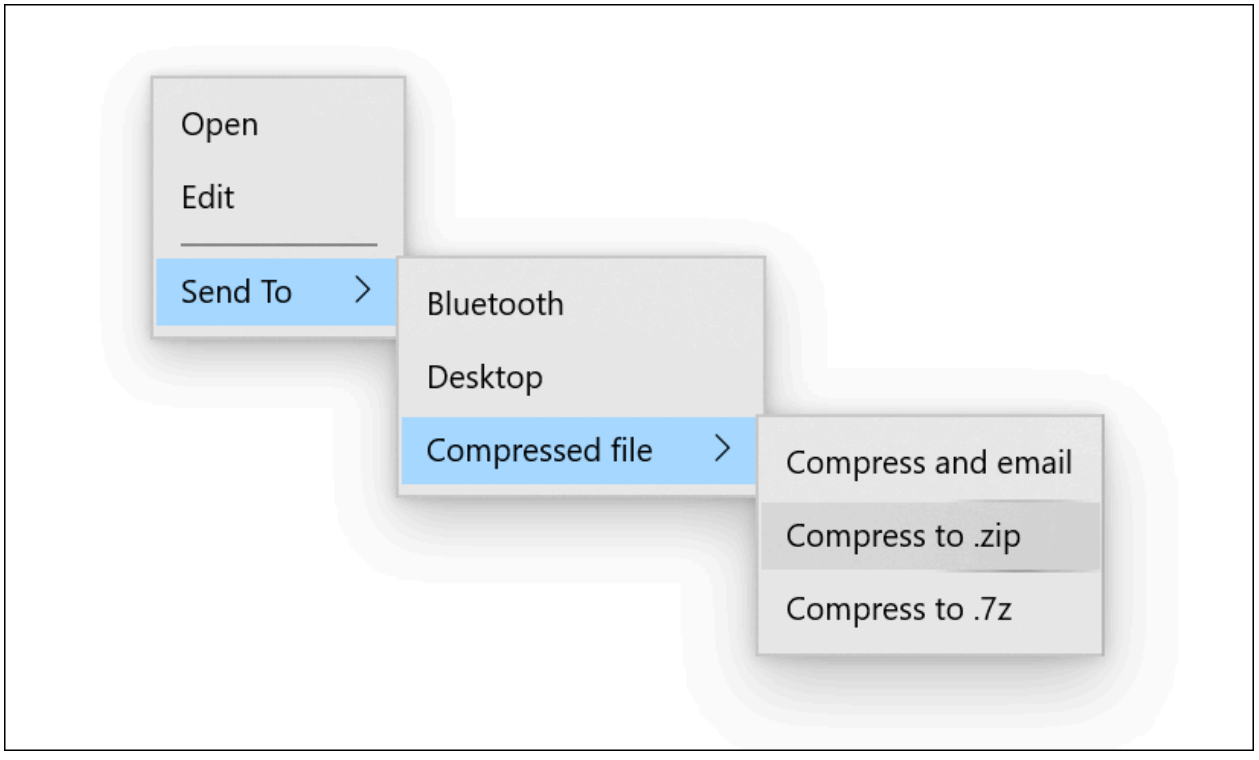
If you use standard controls, shadows are already incorporated into your UI. However, you can manually include shadows in your UI by using either the ThemeShadow or the DropShadow APIs.

ThemeShadow

The ThemeShadow type can be applied to any XAML element to draw shadows appropriately based on x, y, z coordinates.

- It applies shadows to elements based on z-depth value, emulating depth.
- It keeps shadows consistent throughout and across applications thanks to built in shadow aesthetics.

Here is how ThemeShadow has been implemented on a MenuFlyout. MenuFlyout has a built in shadow with a depth of 32px applied to the main menu and all nested menus.



ThemeShadow in common controls

The following common controls will automatically use ThemeShadow to cast shadows from 32px depth unless otherwise specified:

- Context menu, Command bar, Command bar flyout, MenuBar
- Dialogs and flyouts (Dialog at 128px)
- NavigationView
- ComboBox, DropDownButton, SplitButton, ToggleSplitButton
- TeachingTip
- AutoSuggestBox
- Calendar/Date/Time pickers
- Tooltip (16px)
- Number Box
- TabView
- Media transport control, InkToolbar
- BreadcrumbBar
- Connected animation

> **Note**
>
> ThemeShadow was introduced in Windows 10 version 1903 (SDK 18362). It is updated in Windows 11 to use ninegrid shadow instead of projected shadow for better performance.

ThemeShadow in Popups

It is often the case that your app's UI uses a popup for scenarios where you need user's attention and quick action. These are great examples when shadow should be used to help create hierarchy in your app's UI.

ThemeShadow automatically casts shadows when applied to any XAML element in a Popup. It will cast shadows on the app background content behind it and any other open Popups below it.

To use ThemeShadow with Popups, use the `Shadow` property to apply a ThemeShadow to a XAML element. Then, elevate the element from other elements behind it, for example by using the z component of the `Translation` property. For most Popup UI, the recommended default elevation relative to the app background content is 32 effective pixels.

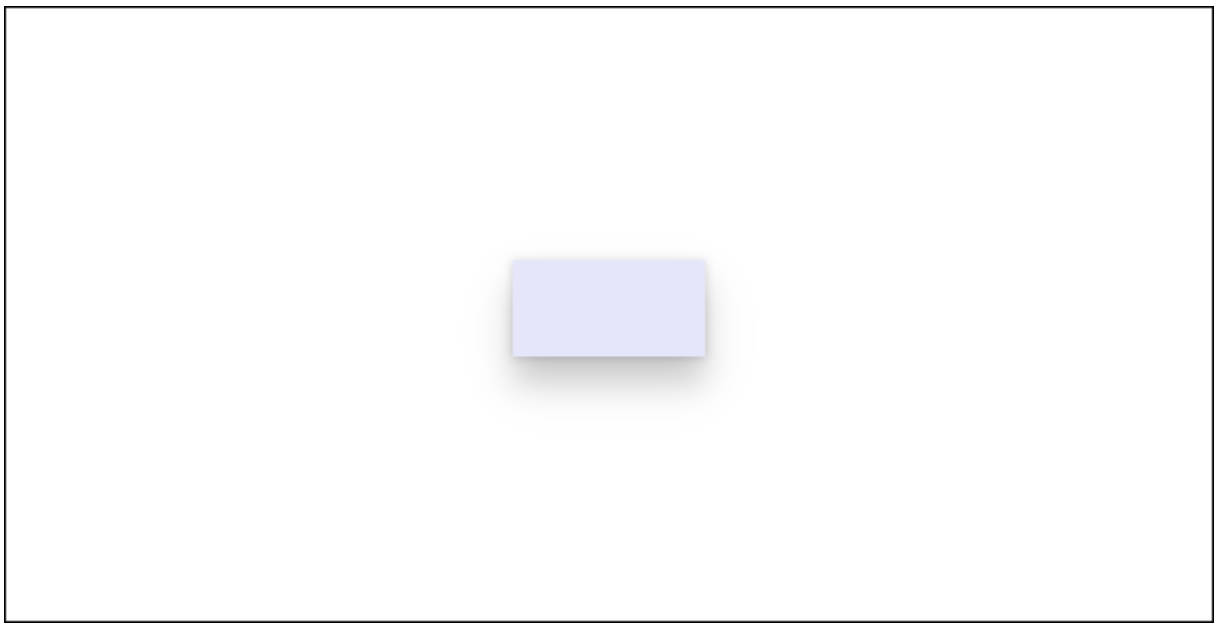
This example shows a Rectangle in a Popup casting a shadow onto the app background content and any other Popups behind it:

XAML

```
<Popup>
    <Rectangle x:Name="PopupRectangle" Fill="Lavender" Height="48"
Width="96">
        <Rectangle.Shadow>
            <ThemeShadow />
        </Rectangle.Shadow>
    </Rectangle>
</Popup>
```

C#

```
// Elevate the rectangle by 32px
PopupRectangle.Translation += new Vector3(0, 0, 32);
```



Disabling default ThemeShadow on custom Flyout controls

Controls based on Flyout, DatePickerFlyout, MenuFlyout or TimePickerFlyout automatically use ThemeShadow to cast a shadow.

If the default shadow doesn't look correct on your control's content then you can disable it by setting the IsDefaultShadowEnabled property to `false` on the associated FlyoutPresenter:

XAML

```
<Flyout>
    <Flyout.FlyoutPresenterStyle>
        <Style TargetType="FlyoutPresenter">
            <Setter Property="IsDefaultShadowEnabled" Value="False" />
        </Style>
    </Flyout.FlyoutPresenterStyle>
</Flyout>
```

ThemeShadow in other elements

> **Note**
>
> Starting with Windows 11, if the app targets the Windows SDK version 22000 or later, the `Receivers` collection is ignored. However there will be no errors and the shadow continues to function.

In general we encourage you to think carefully about your use of shadow and limit its use to cases where it introduces meaningful visual hierarchy. However, we do provide a way to cast a shadow from any UI element in case you have advanced scenarios that necessitate it.

To cast a shadow from a XAML element that isn't in a Popup, you must explicitly specify the other elements that can receive the shadow in the `ThemeShadow.Receivers` collection. Receivers cannot be an ancestor of the caster in the visual tree.

This example shows two Rectangles that cast shadows onto a Grid behind them:

XAML

```
<Grid>
    <Grid.Resources>
        <ThemeShadow x:Name="SharedShadow" />
    </Grid.Resources>

    <Grid x:Name="BackgroundGrid" Background="{ThemeResource
ApplicationPageBackgroundThemeBrush}" />

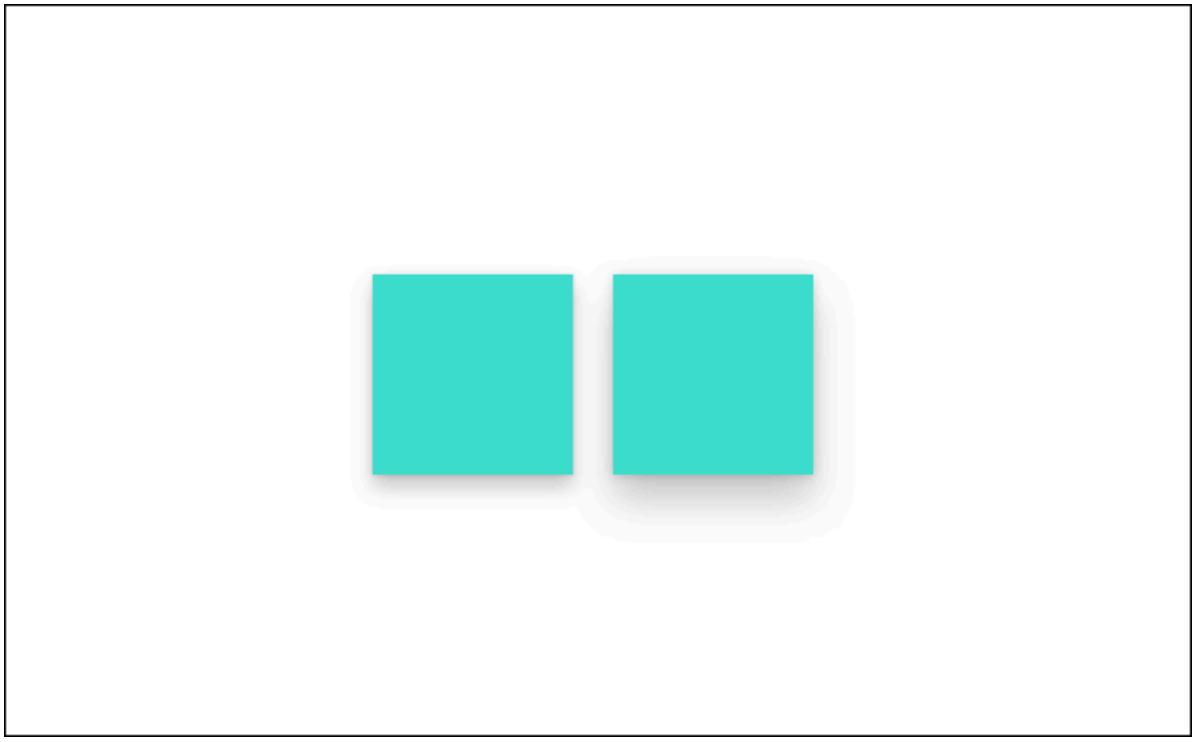
    <Rectangle x:Name="Rectangle1" Height="100" Width="100" Fill="Turquoise"
Shadow="{StaticResource SharedShadow}" />

    <Rectangle x:Name="Rectangle2" Height="100" Width="100" Fill="Turquoise"
Shadow="{StaticResource SharedShadow}" />
</Grid>
```

C#

```
/// Add BackgroundGrid as a shadow receiver and elevate the casting buttons
above it
SharedShadow.Receivers.Add(BackgroundGrid);

Rectangle1.Translation += new Vector3(0, 0, 16);
Rectangle2.Translation += new Vector3(120, 0, 32);
```



Drop shadow

DropShadow does not provide built in shadow values and you need to specify them yourself. For example implementations, see the DropShadow class.

> **Tip**
>
> Starting with Windows 11, if the app targets the Windows SDK version 22000 or later, ThemeShadow will behave like a drop shadow. If you are using DropShadow, you might consider using ThemeShadow instead.

Which shadow should I use?

Expand table

Property	ThemeShadow	DropShadow
Min SDK	SDK 18362	SDK 14393
Adaptability	Yes	No
Customization	No	Yes
Light source	None	None
Supported in 3D environments	Yes (*While it works in a 3D environment, the shadows are emulated.*)	No

- Keep in mind that the purpose of shadow is to provide meaningful hierarchy, not as a simple visual treatment.
- Generally, we recommend using ThemeShadow, which provides consistent shadow values.
- For concerns about performance, limit the number of shadows, use other visual treatment, or use DropShadow.
- If you have more advanced scenarios to achieve visual hierarchy, consider using other visual treatment (for example, color). If shadow is needed, then use DropShadow.

Iconography in Windows

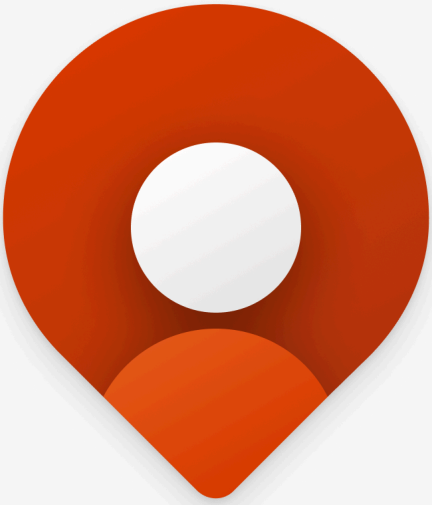
Article • 07/29/2024

Iconography is a set of visual images and symbols that help users understand and move through your app. Icons are used throughout the user interface as visual metaphors that represent a concept, action, or status.

Windows 11 uses three types of icons: application, system, and file type. This article focuses on the first two.

> **Tip**
>
> This article describes how the Fluent Design language is applied to Windows apps. For more information, see Fluent Design - Iconography.

Application icons



Application icons represent your app in the Windows shell. They're primarily used to open your application, but they also represent your app wherever it appears in the Windows shell.

App icons should represent your app's core functionality through a metaphor. For more information about designing and constructing your app's icon, see **App icons**.

System icons

Use system icons inside your app UI for items like command bars, navigation, or status indicators. Windows 11 introduces a new system icon font, Segoe Fluent Icons. This new font complements geometry in Windows 11.

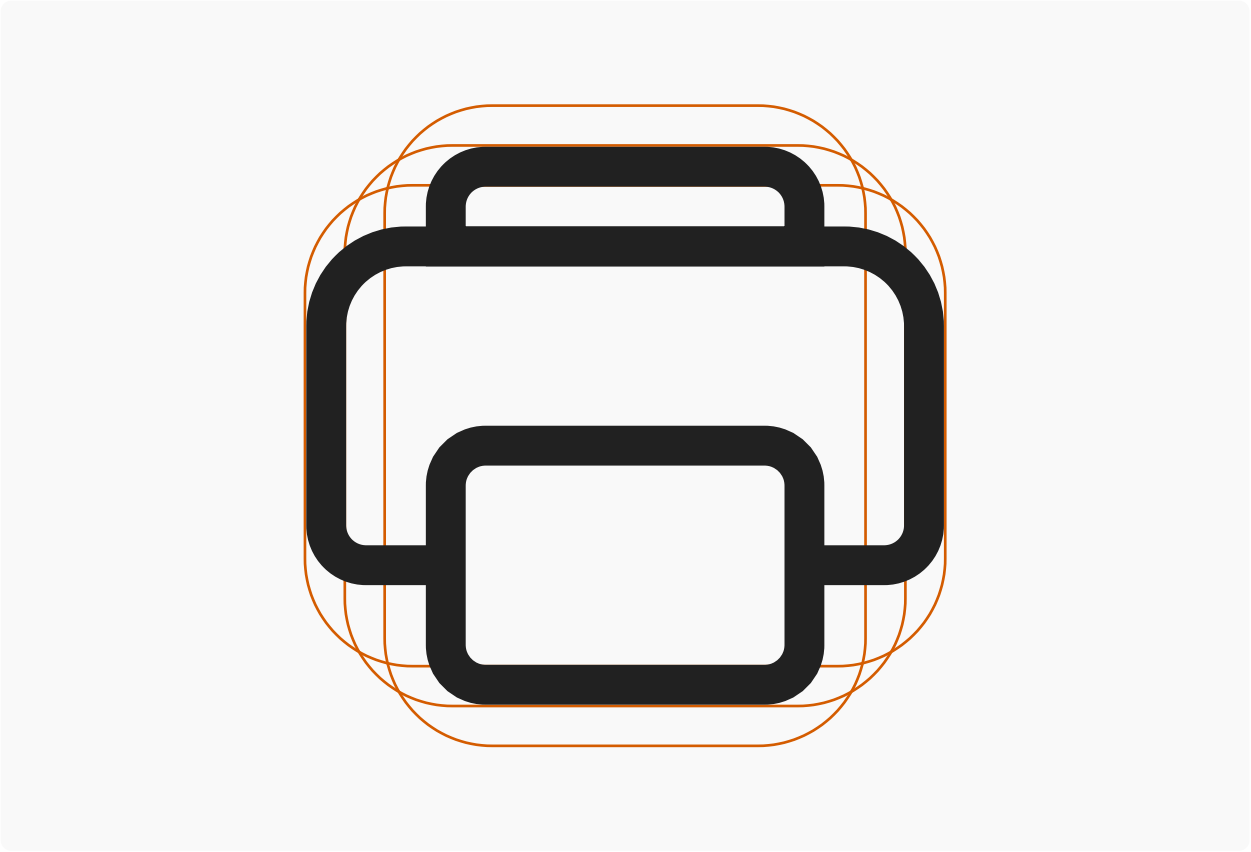
All glyphs in Segoe Fluent Icons are drawn in a monoline style. That means they're created through a single stroke of 1 epx.

Glyphs in Segoe Fluent Icons follow three aesthetic principles:

- **Minimal**: Glyphs contain only the details that are necessary to communicate the concept.
- **Harmonious**: Glyphs are based on simple and geometric forms.
- **Evolved**: Glyphs use modern metaphors that are easily understood.

For more information about using icons in your app UI, see **Icons in Windows apps**.

Icon size



Font metrics for Segoe Fluent Icons match how designers and developers are accustomed to working with SVG and bitmap icons.

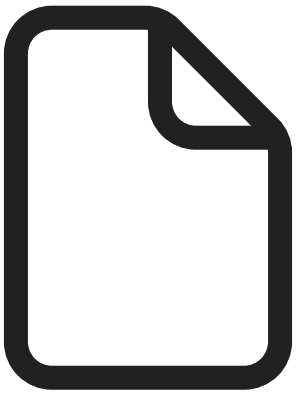
Each font glyph is designed so that the footprint of the icon area is a square em. An icon with a 16-epx font size is the equivalent of a 16x16-epx icon, to make sizing and positioning more predictable.

Modifiers

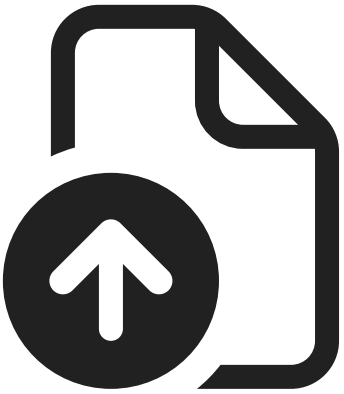
You can visually construct system icon glyphs by combining a base icon with a modifier icon.

Base icons are the main element of a visual metaphor. Base elements should occupy the entire icon footprint.

Modifier icons modify the meaning of the base icon. Modifier elements should be placed in one of the bottom quadrants of the icon footprint.



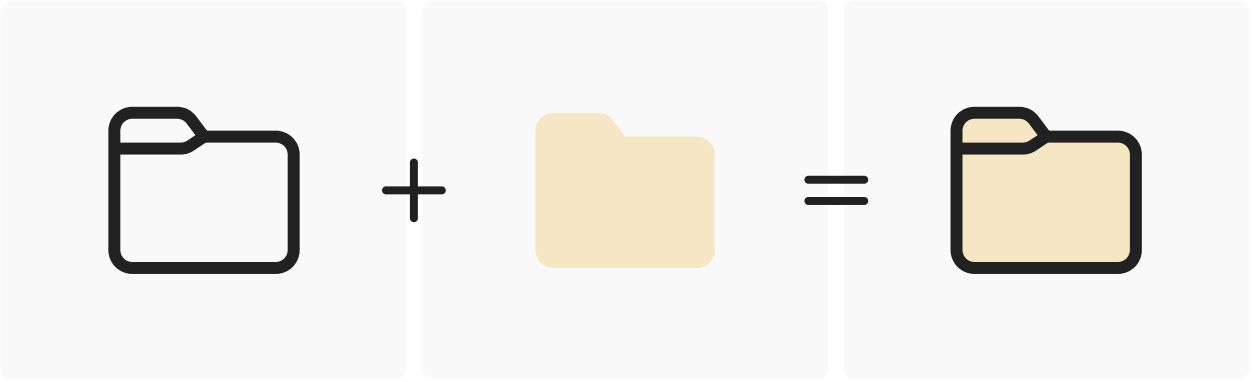
Base icon only
On its own, the paper sheet icon communicates the concept of a *file*.



Base icon + modifier icon
Adding an up arrow to the file icon changes the meaning of the icon to represent an *uploaded file*.

Layering

Icon layering is a technique that you use to overlap two glyphs. We recommend using icon layering to create a different state of the same icon (for example, an active or selected state).



Localization

Understand the cultural connotations of symbols. Although iconography doesn't require localization in most cases, certain icons might be acceptable in one culture but not in another. Validate your iconography choices with the context in which you'll use them.

Examples

Open the WinUI 3 Gallery app and see Iconography principles in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

App icons

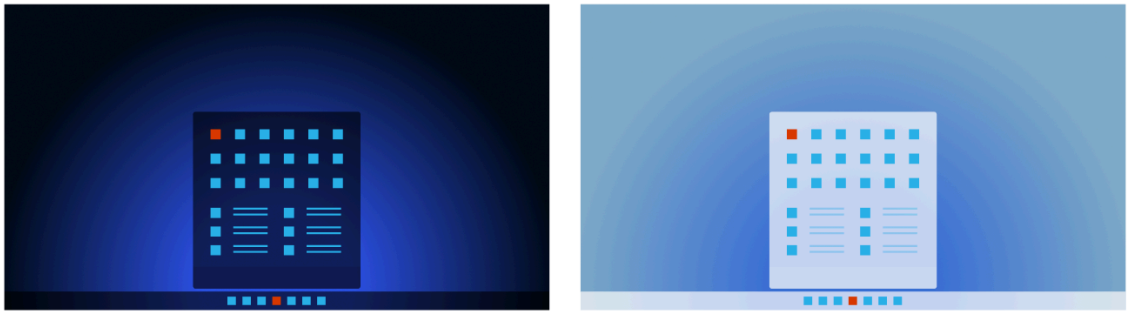
Article • 07/29/2024

App icons are the visual indicators we use to help users find and launch an application on Windows.

It's the first impression of your app and we want to help make sure it's a great one. This article covers the best practices for Windows app icon design and implementation to provide the best experience in the Windows ecosystem.

> **Tip**
>
> This article describes icons that represent your app in Windows and the Windows Store. To learn about icons that you use inside your app UI, see **Icons in Windows apps**.

Where do app icons appear?



App icons appear in a variety of places in Windows:

- Start menu
- Start menu's 'All apps' list
- Taskbar
- Splash screen
- App title bar
- Search results
- Notifications
- "Open with" list
- Task manager
- JumpLists

- Settings
- Share dialog

Principles for great app icons

Keep it simple

Create clean, straightforward, timeless designs — Icons are quick visual cues that represent your app. Simple, easy to understand designs help users recognize your app more quickly.

Keep it universal

Make it accessible, inviting, and easy to understand — Avoid complex or overly abstract forms. An intricate shape may be appropriate in some cultures but not in others. Inclusive icons are better for everyone. We focus on human unifiers – our motivations, relationships, and capabilities. We design to extend human abilities and create a sense of belonging.

Do less, better

When every detail is thoughtfully crafted, delight happens — The best apps offer beautiful design and reliable experiences. Your icon should illustrate your app in a singular element using simple forms.

Design and create your app's icon

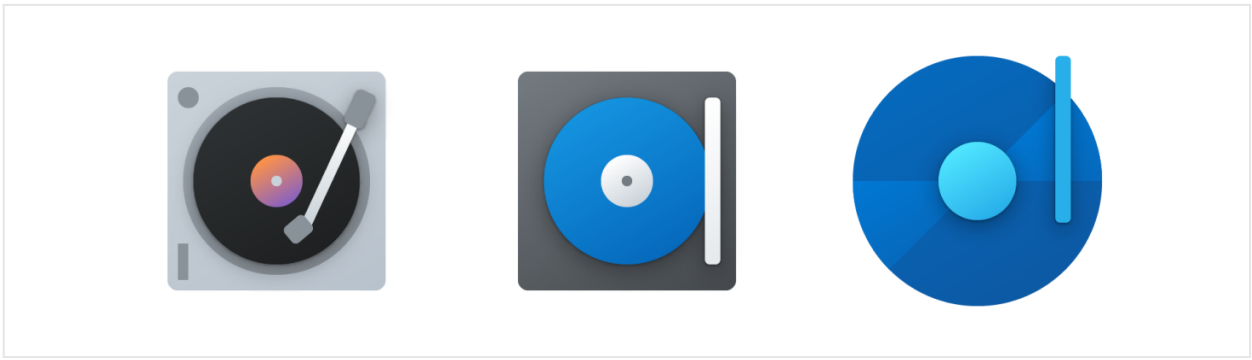
- Design guidelines for Windows app icons — Learn how to use metaphor, shape, color, and shadow to design a beautiful and functional icon for your app.
- Construct the icon for your Windows app — Create icons that look good at any size, on any screen.
- Construction guidelines for Windows 10 icons — If your app runs on Windows 10, your app's icons will be displayed in Live Tiles. Learn more about additional considerations for icons on Windows 10.

Design guidelines for Windows app icons

Article • 03/13/2023

Follow these guidelines to create a great app icon for your app that feels at home on Windows.

Design guidance: Metaphor

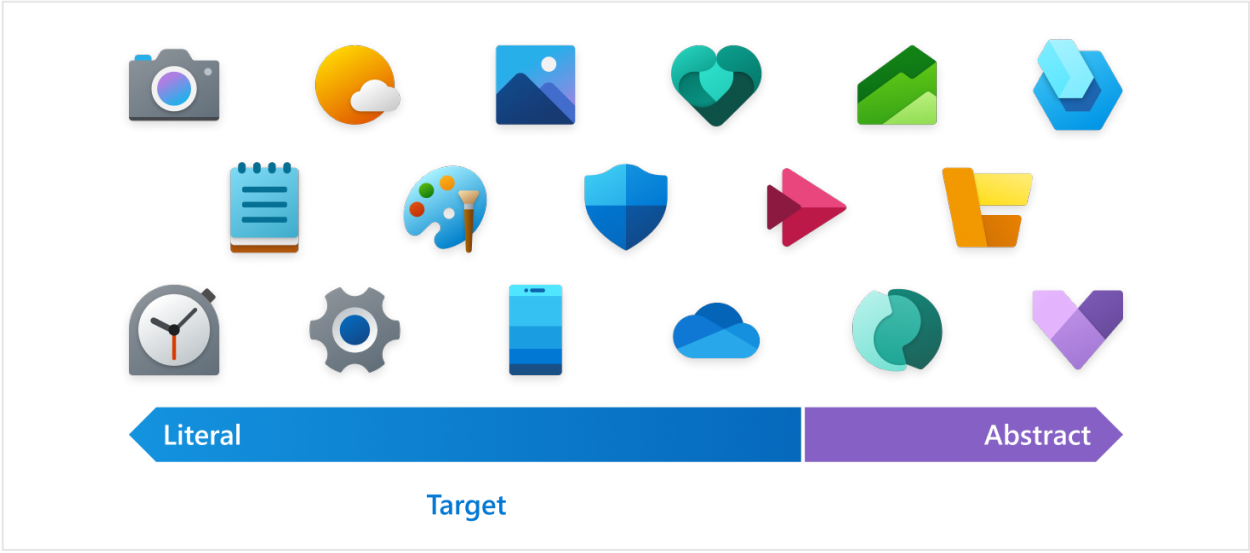


An icon should be a metaphor for its app: a visual representation of the value proposition, functions, and features of the product.

Representation

Your icon should illustrate the concept of your app in a singular element using simple forms.

When creating your icon, use clear metaphors and leverage concepts that are largely understood - such as an envelope for mail or magnifying glass for search. The key concept should be your icon's focal point; don't dilute your icon by adding decorative elements that don’t support the metaphor. To enhance communication clarity, use no more than two metaphors in a single icon. If a single metaphor can be used, that’s even better.



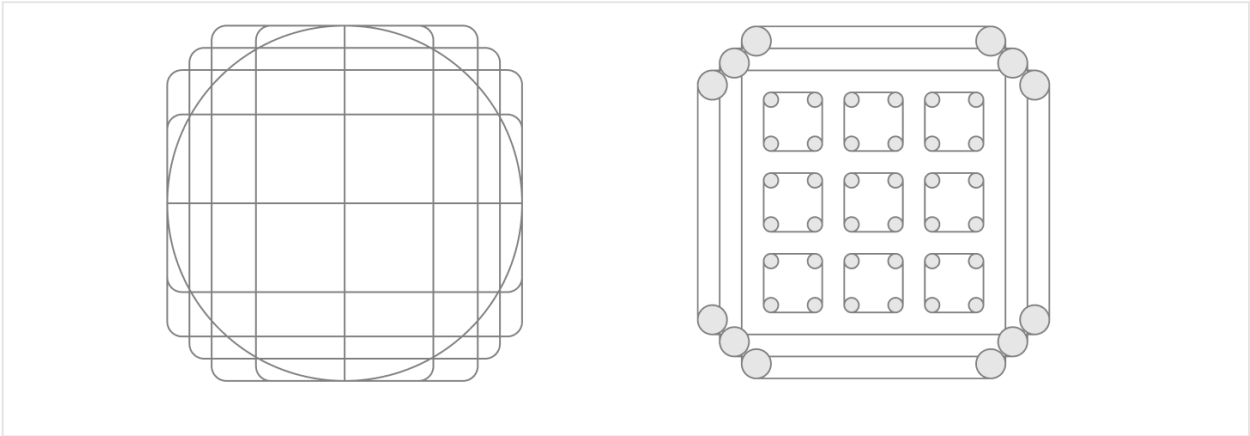
Literal metaphors are best for articulating the purpose and promise in a clear way. A good test for an effective icon is when users can tell what it represents without a label.

Only use an abstract metaphor in instances where it's impossible to find a literal, self-evident metaphor to represent the core functionality of a product.

Icons should not include typography as part of the design. Letters and words on your icon should be avoided and only used when it’s essential. The app’s name will appear in association with the icon throughout the operating system.

Design guidance: Shape

The grid and rounded corners



Microsoft aligns its icons to a 48x48 grid initially to ensure a balanced icon that takes advantage of the space available, while still maintaining a distinctive shape and silhouette. Aligning your icon's distinctive features to the grid will balance well with the other icons around it.

Approachability is a Microsoft personality principle. One way we communicate this trait is by using soft or rounded corners. Shapes used in your app's product icons should be built to align with the icon grid. The corners of these shapes should match the rounded corners in the icon grid. When rounded corners are applied to an exterior curve, use a 2px radius at 48x48. When rounded corners are applied to an interior curve, use a 1px radius instead.

Silhouette

A visually balanced silhouette allows good icon scalability and also avoids extremes of thick and thin shapes. Use the grid to design a silhouette that’s distinctive, yet legible at small sizes. Use as few shapes with as few corners as possible to distinguish your product while still feeling at home on Windows.

Detail

When adding detail, care should be taken to maintain legibility at small sizes. It is recommended to only add additional literal detail to the most prominent layer of an icon.

Design guidance: Color and gradients

Pick colors carefully and avoid relying on color alone to convey meaning. Use shape and metaphor with color to communicate. To avoid complexity when scaling an icon across a range of sizes, treatments to colors should be minimized. Color gradients, overlays of varying opacity, and tints of color should be kept to a minimum.

Gradients should be subtle for the most part. Try to limit your gradient ramps to only one or two steps in both the horizontal and vertical directions.

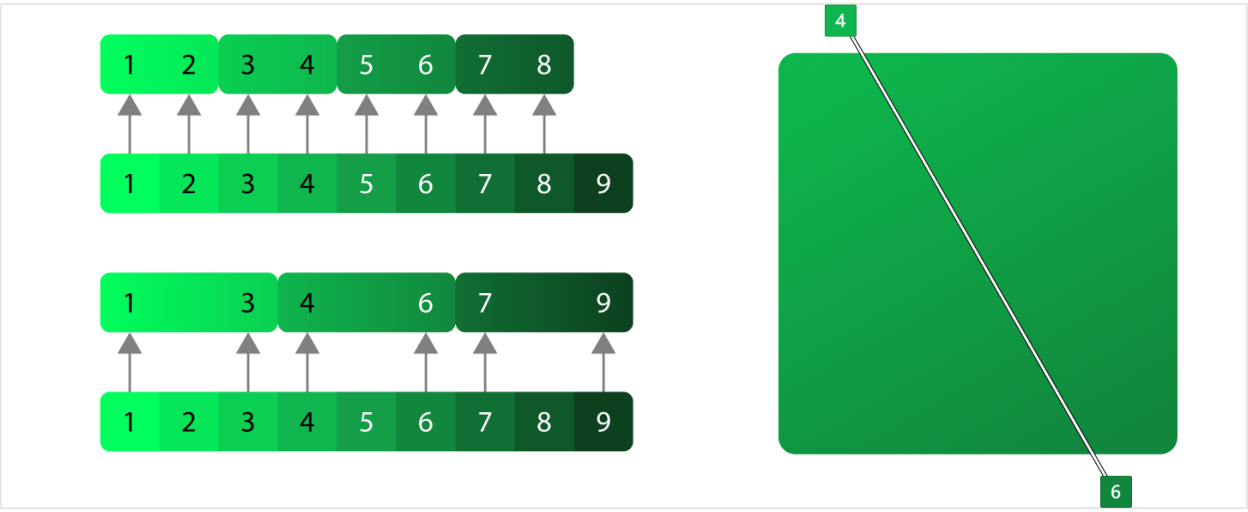
The default angle for gradients is 120 degrees. Start and end points can be adjusted accordingly. The important thing is that it’s a smooth transition. Avoid very tight transitions that would feel like reflections or dimension.

Monochrome palette

Create a monochrome palette using the following steps:

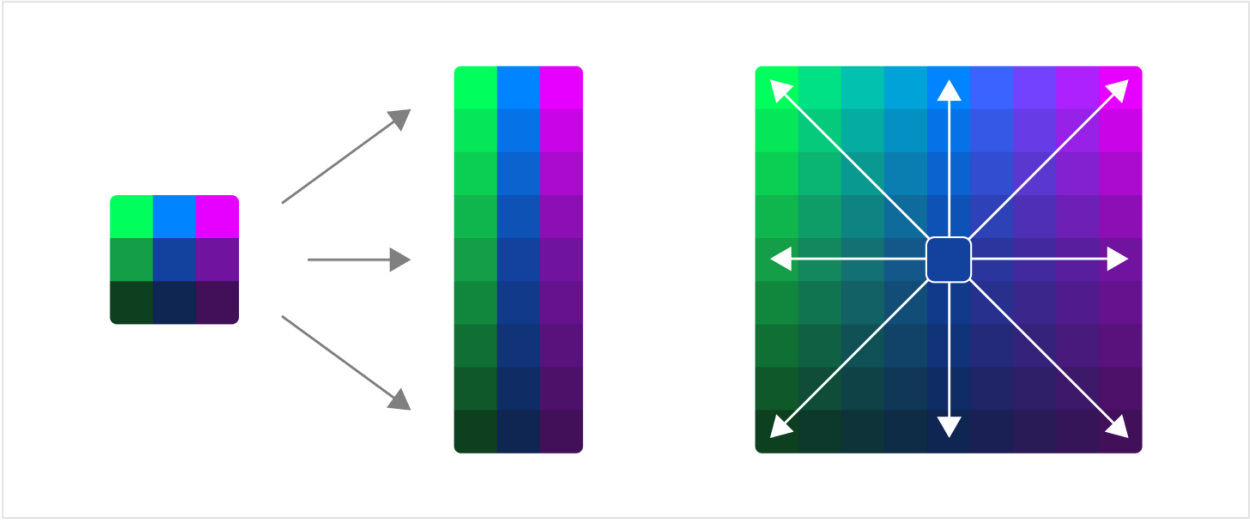
1. Create three colors from the same hue. In most cases you will have to adjust the light color to be brighter and the dark color to be less saturated, but of course you should use your best judgement.
2. Create three steps in between each base color. This will be your primary lane. Most of the icon should be comprised of these colors.
3. For a wider palette, create tints to white and shades to black using the same method as step 2. These tints and shades should be used only when you need a little more contrast.
4. The tints of the dark colors and shades of the light colors are usually useless and drab. They can be removed.

Monochrome gradients



Monochrome gradients are usually used to give a subtle hint toward an ambient light angle coming from the top left. They should not be treated as a direct light source though. The idea is to give the shapes a little movement without being too dramatic.

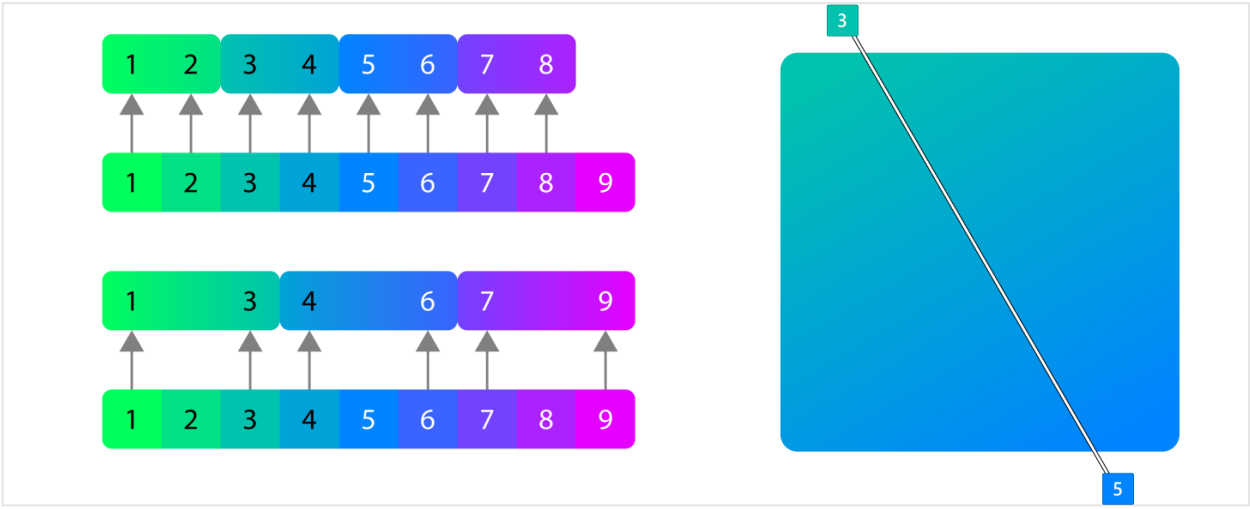
Analogous palette



Creating an analogous palette is exactly like creating a monochrome palette, but with more colors. The key to this type of palette is not to overdo it. Be thoughtful with your color transitions.

1. Create three color sets instead of one.
2. Make vertical ramps out of all three color sets.
3. Instead of creating tints and shades using white and black, use your second and third colors instead.

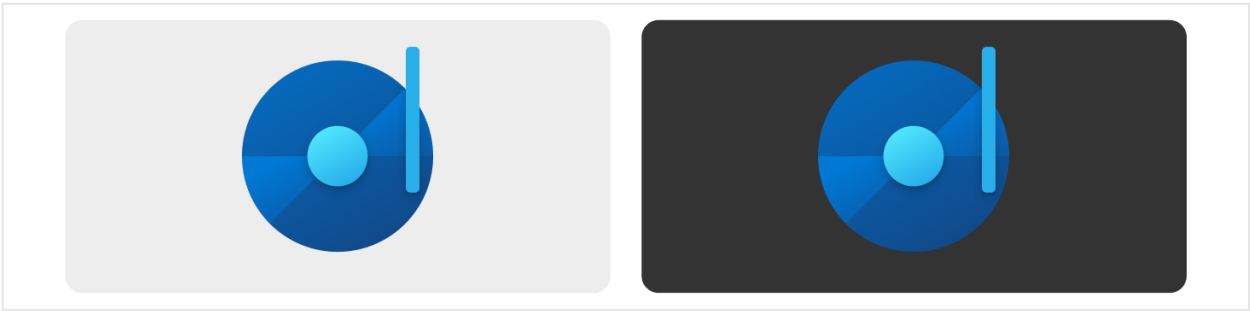
Analogous gradients



Analogous gradients should be at the same angle as the monochrome, but don't always have to be. Typically lighter hues should be on top left to avoid looking overly dramatic but also to be as consistent as possible with the monochrome.

Design guidance: Contrast, shadow, and perspective

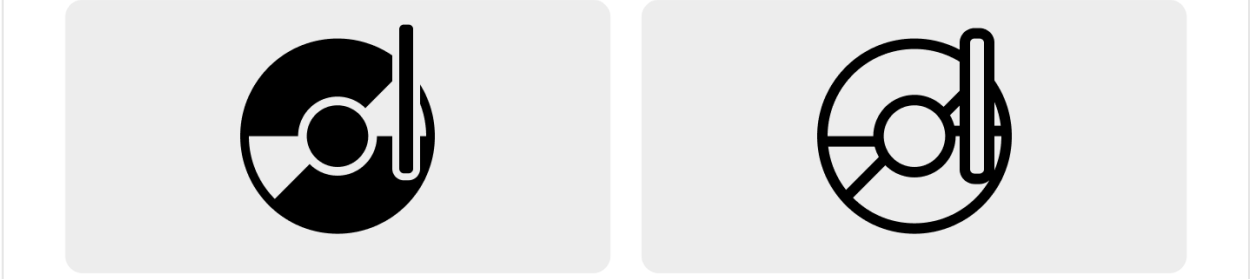
Color contrast



Accessibility is a high priority for Microsoft. App icons are primarily displayed on either light and dark backgrounds but displayed over desktop background images and tints or shades of the system accent color. It is difficult to make an icon 100% accessible on every background, but there are several things you can do to ensure your icon is as accessible as possible.

- Use color values in all 3 ranges, dark, medium, light.
- Make sure at least half of your icon passes a 3.0:1 contrast ratio on light and dark theme.
- Some hue values are more difficult than others. Yellow will never pass an accessible contrast ratio on light theme until it's brown. Reds are more difficult on dark theme.
- Though not required, you have the option to provide separate light and dark theme assets for Taskbar, Start and other theme-sensitive areas of Windows.

High contrast

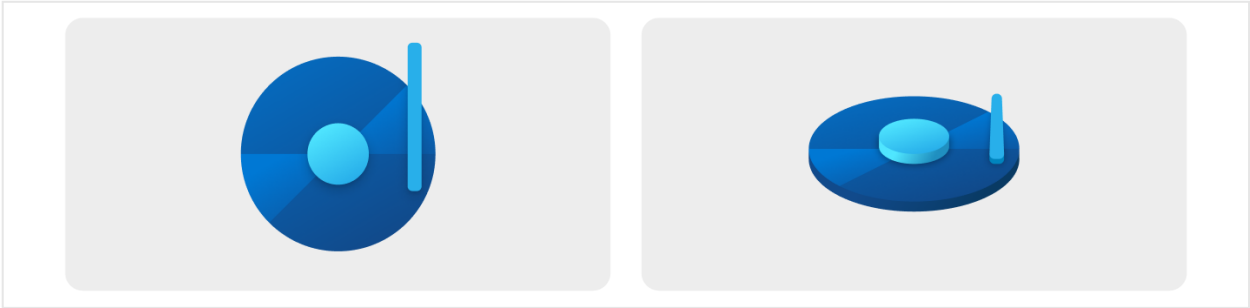


> **Tip**
>
> Windows 11 no longer requires high contrast assets for app icons.

High contrast icons are black and white and should be a direct representation of your app icon. Often the high contrast icon can be created from the color version using a

solid fill and line. Avoid gradients in high contrast icons. Sometimes monoline icons are required for in-app experiences should be designed according to these guidelines.

Layering and shadow



Top/Front facing view.

Isometric view to illustrate z-depth. For illustrative purposes only; not a suggested design option.

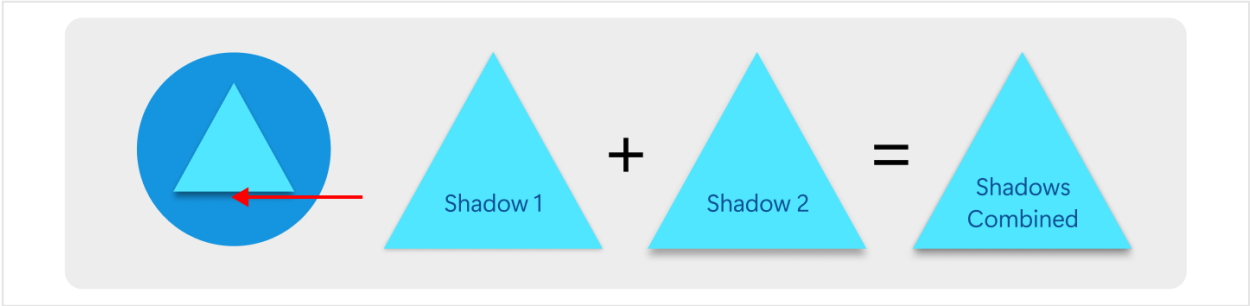
Icons are composed of flat objects sitting on top of the layers below it.

- Use as few layers as possible, and minimize extreme contrasts of scale between shapes.
- Use drop shadows within icons to create definition between object layers and visually connect components to each other within the icon design.
- In general, shadows cast from light onto dark shapes have the best result.
- Inner shadows should only cast a shadow on the graphic symbol, not on to the surrounding background.
- There are two types of inner shadow both of which have two shadows each

Shadow construction

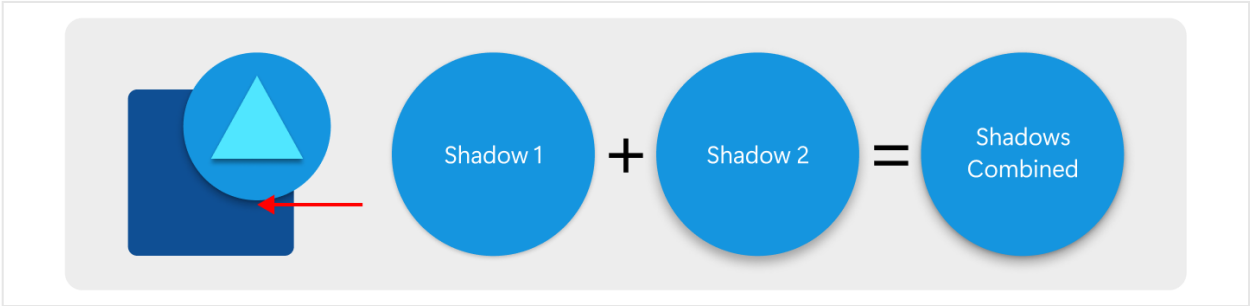
All of these values are to be rendered at 48x48 px and scaled up or down from there. If this is not adhered to, shadows will be inconsistent across the icon system. There are two types of object shadows both of which have two shadows each. Objects within the same metaphor have a shadow with slightly less blur.

Same metaphor



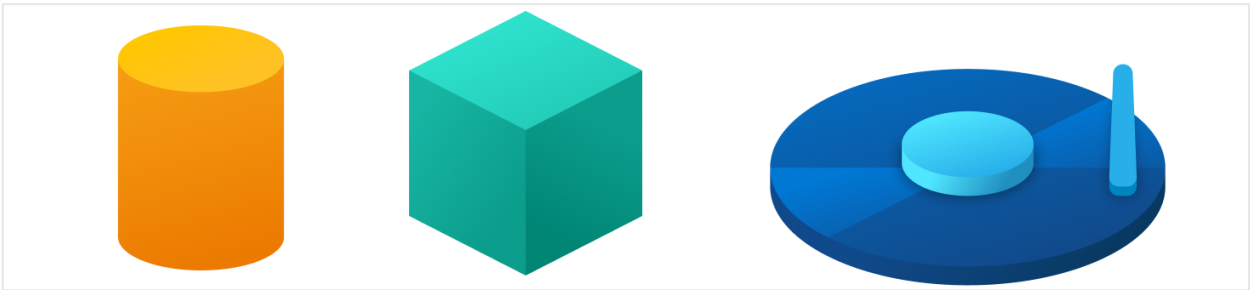
This shadow is used when you have content within a single metaphor that needs some depth. It's not always necessary to do this, but single object metaphors need some depth to feel like part of the system. the blue on shadow 2 is the only difference.

Separate metaphor



This shadow is used when you have two objects that overlap each other but are not necessarily part of the same metaphor. The shadow should be masked into the shape below it.

Perspective



The icons on the left are fairly simple; perspective is not recommended, but may be appropriate here. The icon on the right is too complex for perspective, so using it for this icon is not recommended.

Icons should be drawn with a straight-on perspective to present the metaphor in a simple easy to understand way. Exceptions are cases where the metaphor doesn't read well without viewing another side of it. For example a cylinder viewed straight on is a rectangle so the top could be added to show that it has volume. The other exception is

when an app is related to 3d where it makes sense to show dimension. In both cases the previous guidelines about flat objects still applies. Layers should always be flat and perpendicular to the viewing angle.

Construct your Windows app's icon

Article • 06/02/2022

Once you've designed your app's icon, you need to create the icon files themselves. Because Windows supports multiple themes, display resolutions, and scale factors, you should provide multiple versions of your icon to make sure it looks great on every device, at any size.

Icon sizes (WPF, UWP, WinUI)

Windows will display your app icon at a variety of sizes depending on where your icon is being displayed and the user's display scale settings. The following table lists all the possible sizes that Windows may use to display your icon.

Icon sizes (Win32)

Windows ICO files have been around for a long time. There are standard sizes that are used which is a subset of the full set above.

Icon scaling

When Windows displays your app's icon, it will look for an exact size match first. If there is no exact match it will look for the next size above and scale down. Including more icon sizes with your app means Windows will more often have a pixel-perfect match, and reduce the amount of scaling applied to scaled icons.

Expand table

Windows 11 scale factor	100%	125%	150%	200%	250%	300%	400%
Context menu, title bar, system tray	16px	20px	24px	32px	40px	48px	64px
Taskbar, search results, Start all apps list	24px	30px	36px	48px	60px	72px	96px
Start pins	32px	40px	48px	64px	80px	96px	256px

> **Note**
>
> Apps should have, at the bare minimum: 16x16, 24x24, 32x32, 48x48, and 256x256. This covers the most common icon sizes, and by providing a 256px icon, ensures Windows should only ever scale your icon down, never up.

Transparent backgrounds

Icons look best with a transparent background. If your app's branding requires your icon be plated on a background, that's okay too. However, you'll have to re-implement some theming functionality that transparent icons get for free. For example, you might provide a version of your app's icon plated on a two different backgrounds, one better suited to a light theme and the other to a dark theme.

Complete list of icons and variations

Windows utilizes different icon assets in different UI contexts. The usage has changed a little between Windows 10 & Windows 11.

The lists below define the specific filenames Windows expects to contain each corresponding icon.

App icon

In Windows 10 and 11, the AppList icon is your app's primary icon. It will be used in several places, including the Taskbar, Start pins, the all app list, and the search results list. Windows 11 selects an appropriate icon for the all apps list based on the current scale factor, but Windows 10 uses specific, explicitly defined icons if you provide them.

Separate files for all three theme variations (default, light theme, dark theme) are required, even if the icon is the same. If you do not provide these files, your icon will appear on a system icon plate to ensure a minimum contrast ratio.

App List Target Size (Required)

- AppList.targetsize-16.png
- AppList.targetsize-20.png
- AppList.targetsize-24.png
- AppList.targetsize-30.png
- AppList.targetsize-32.png
- AppList.targetsize-36.png
- AppList.targetsize-40.png
- AppList.targetsize-48.png
- AppList.targetsize-60.png
- AppList.targetsize-64.png
- AppList.targetsize-72.png
- AppList.targetsize-80.png
- AppList.targetsize-96.png
- AppList.targetsize-256.png

Dark theme (Required)

- AppList.targetsize-16_altform-unplated.png
- AppList.targetsize-20_altform-unplated.png
- AppList.targetsize-24_altform-unplated.png
- AppList.targetsize-30_altform-unplated.png
- AppList.targetsize-32_altform-unplated.png
- AppList.targetsize-36_altform-unplated.png
- AppList.targetsize-40_altform-unplated.png
- AppList.targetsize-48_altform-unplated.png
- AppList.targetsize-60_altform-unplated.png
- AppList.targetsize-64_altform-unplated.png
- AppList.targetsize-72_altform-unplated.png
- AppList.targetsize-80_altform-unplated.png
- AppList.targetsize-96_altform-unplated.png
- AppList.targetsize-256_altform-unplated.png

Light theme (Required)

- AppList.targetsize-16_altform-lightunplated.png
- AppList.targetsize-20_altform-lightunplated.png
- AppList.targetsize-24_altform-lightunplated.png
- AppList.targetsize-30_altform-lightunplated.png
- AppList.targetsize-32_altform-lightunplated.png
- AppList.targetsize-36_altform-lightunplated.png

- AppList.targetsize-40_altform-lightunplated.png
- AppList.targetsize-48_altform-lightunplated.png
- AppList.targetsize-60_altform-lightunplated.png
- AppList.targetsize-64_altform-lightunplated.png
- AppList.targetsize-72_altform-lightunplated.png
- AppList.targetsize-80_altform-lightunplated.png
- AppList.targetsize-96_altform-lightunplated.png
- AppList.targetsize-256_altform-lightunplated.png

App List Scale (Windows 10) (Optional)

- AppList.scale-100.png
- AppList.scale-125.png
- AppList.scale-150.png
- AppList.scale-200.png
- AppList.scale-400.png

Light theme (Windows 10) (Optional)

- AppList.scale-100_altform-colorful_theme-light.png
- AppList.scale-125_altform-colorful_theme-light.png
- AppList.scale-150_altform-colorful_theme-light.png
- AppList.scale-200_altform-colorful_theme-light.png
- AppList.scale-400_altform-colorful_theme-light.png

> ⓘ **Note**
>
> If you do not include the targetsize-*-altform-unplated assets above your icon will scale to a smaller size and will get an undesirable backplate behind the icon on Taskbar and Start.

Tiles

Windows 10 supports four tile sizes: small, medium, wide, and large.

Default / dark theme (partially required)

- SmallTile.scale-100.png
- SmallTile.scale-125.png
- SmallTile.scale-150.png
- SmallTile.scale-200.png
- SmallTile.scale-400.png

- MedTile.scale-100.png
- MedTile.scale-125.png
- MedTile.scale-150.png
- MedTile.scale-200.png
- MedTile.scale-400.png

- WideTile.scale-100.png
- WideTile.scale-125.png
- WideTile.scale-150.png
- WideTile.scale-200.png
- WideTile.scale-400.png

- LargeTile.scale-100.png
- LargeTile.scale-125.png
- LargeTile.scale-150.png
- LargeTile.scale-200.png
- LargeTile.scale-400.png

Light theme (optional)

- SmallTile.scale-100_altform-colorful_theme-light.png
- SmallTile.scale-125_altform-colorful_theme-light.png
- SmallTile.scale-150_altform-colorful_theme-light.png
- SmallTile.scale-200_altform-colorful_theme-light.png
- SmallTile.scale-400_altform-colorful_theme-light.png

- MedTile.scale-100_altform-colorful_theme-light.png
- MedTile.scale-125_altform-colorful_theme-light.png
- MedTile.scale-150_altform-colorful_theme-light.png
- MedTile.scale-200_altform-colorful_theme-light.png
- MedTile.scale-400_altform-colorful_theme-light.png

- WideTile.scale-100_altform-colorful_theme-light.png
- WideTile.scale-125_altform-colorful_theme-light.png
- WideTile.scale-150_altform-colorful_theme-light.png
- WideTile.scale-200_altform-colorful_theme-light.png
- WideTile.scale-400_altform-colorful_theme-light.png

- LargeTile.scale-100_altform-colorful_theme-light.png
- LargeTile.scale-125_altform-colorful_theme-light.png
- LargeTile.scale-150_altform-colorful_theme-light.png
- LargeTile.scale-200_altform-colorful_theme-light.png
- LargeTile.scale-400_altform-colorful_theme-light.png

> **Note**
>
> Windows 11 does not use the tile assets, but currently at minimum the Medium tile assets at 100% are required to publish to the Microsoft Store. If your app is Windows 10 & 11 compatible it is suggested that you include as many tile assets as possible.

Splash screen

Splash screens can also be Light and Dark theme aware like the App icon assets.

Default

- SplashScreen.scale-100.png
- SplashScreen.scale-125.png
- SplashScreen.scale-150.png
- SplashScreen.scale-200.png
- SplashScreen.scale-400.png

Dark theme (Optional)

- SplashScreen.scale-100_altform-colorful_theme-dark.png
- SplashScreen.scale-125_altform-colorful_theme-dark.png
- SplashScreen.scale-150_altform-colorful_theme-dark.png
- SplashScreen.scale-200_altform-colorful_theme-dark.png
- SplashScreen.scale-400_altform-colorful_theme-dark.png

Light theme (Optional)

- SplashScreen.scale-100_altform-colorful_theme-light.png
- SplashScreen.scale-125_altform-colorful_theme-light.png
- SplashScreen.scale-150_altform-colorful_theme-light.png
- SplashScreen.scale-200_altform-colorful_theme-light.png
- SplashScreen.scale-400_altform-colorful_theme-light.png

Badge logo

Badge icons are used on the Windows 10 lock screen and for most apps are not required.

Windows 10 (optional)

- BadgeLogo.scale-100.png
- BadgeLogo.scale-125.png
- BadgeLogo.scale-150.png
- BadgeLogo.scale-200.png
- BadgeLogo.scale-400.png

Package logo (Microsoft Store logo)

These assets are required to publish to the Microsoft Store.

Default / Dark theme (required)

- StoreLogo.scale-100.png
- StoreLogo.scale-125.png
- StoreLogo.scale-150.png
- StoreLogo.scale-200.png
- StoreLogo.scale-400.png

Light theme (optional)

- StoreLogo.scale-100_altform-colorful_theme-light.png
- StoreLogo.scale-125_altform-colorful_theme-light.png
- StoreLogo.scale-150_altform-colorful_theme-light.png
- StoreLogo.scale-200_altform-colorful_theme-light.png
- StoreLogo.scale-400_altform-colorful_theme-light.png

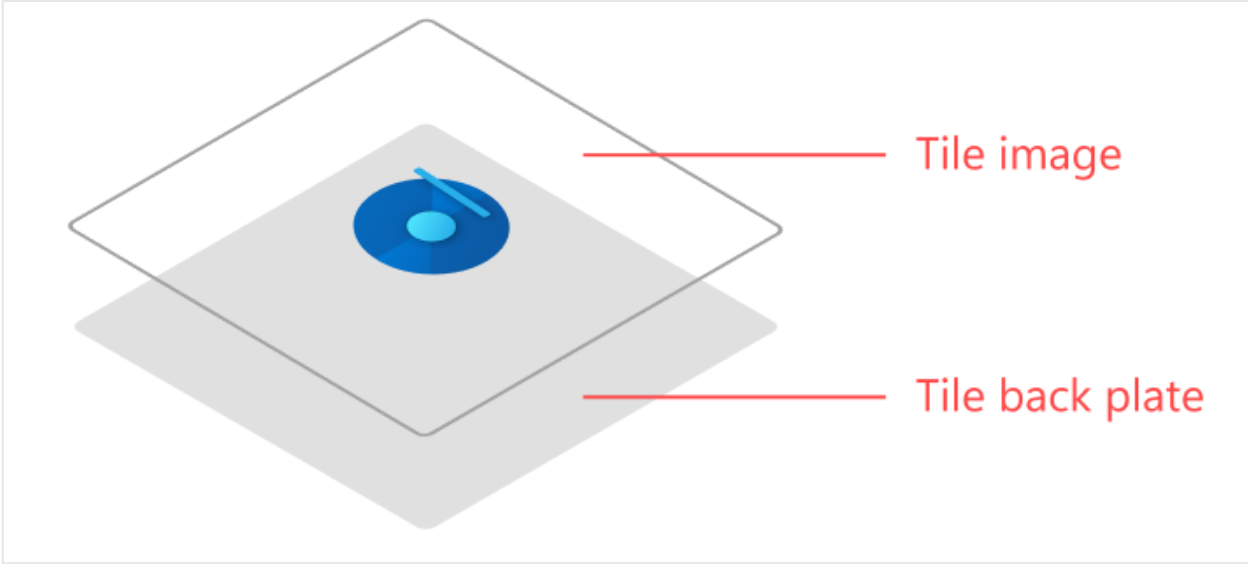
Construction guidelines for Windows 10 icons

Article • 06/02/2022

Apps running on versions of Windows with Live Tile support have additional options for how their app's icon is displayed within its tile. Apps that choose to provide tile images should provide images for all tile sizes at all common scale factors.

Windows 10 October 2020 Update introduced theme-aware Start Menu tiles, which select the tile background color based on the user's theme rather than using the color specified in the VisualElement section of the application manifest. Apps can still choose a color that suits their tile background color for versions of Windows 10 prior to October 2020.

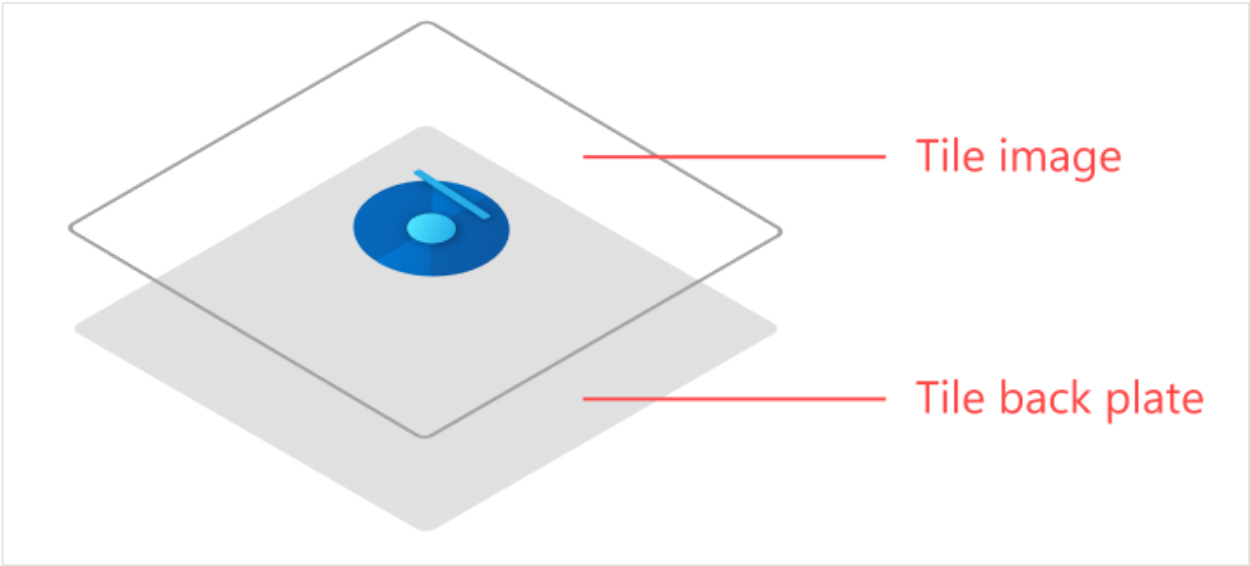
Creating an icon-based tile



The easiest way to look great on Live Tiles is to just display your app's icon against a transparent background. This is the "standard" way to do tiles. To achieve this look, you can either create tile images with transparent backgrounds, or just let Windows display your app's icon on a regular tile.

Creating a full bleed tile

When required, apps can create full-bleed Live Tile images to fully customize their tile. Typically, this functionality is used by games. Non-game apps should generally not use full-bleed tiles, because it will make your tile stand out awkwardly compared to "standard" icon-based tiles. Full bleed tiles can be used to achieve several looks.



Apps using a full bleed tile can make their icon any size they want. To do this, simply make your icon the size you would like it to display when the tile is shown. App icons should never take up the complete tile. Be sure to use at least 16% margins on each side.

Some apps, usually games, might want to display a full-bleed image instead of an icon. In this case, do not use margins - the image should take up all available space.

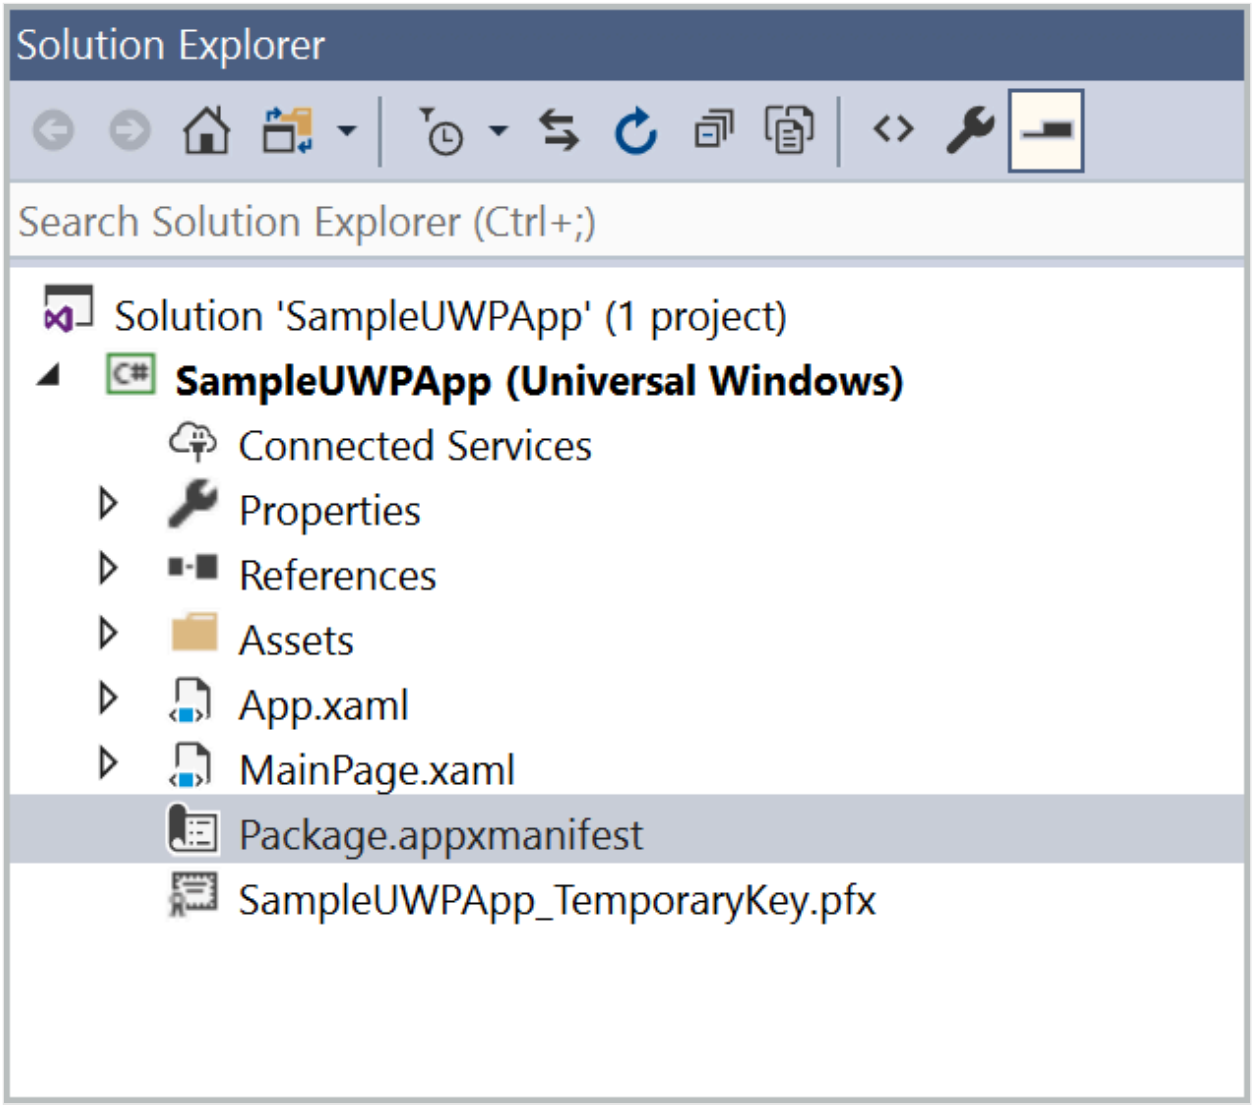
Create icons using Visual Studio's asset generation tool

Article • 05/24/2022

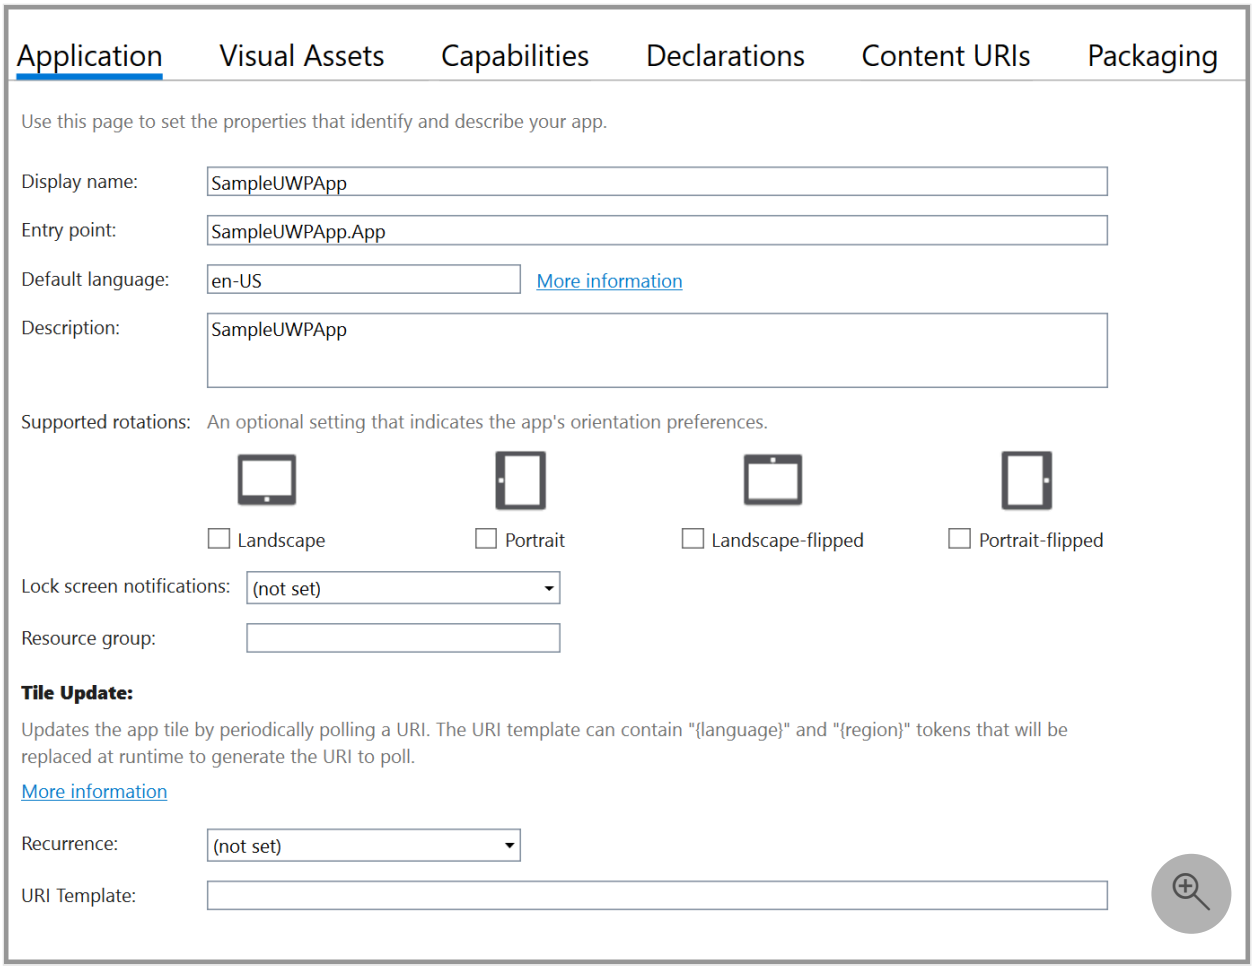
While handcrafting each icon file will create the best, most consistent user experience, teams running short on resources can take advantage of Visual Studio's Manifest Designer. This tool can create an entire set of app icons and tile images from a single image. This is useful to create an initial set of icons, but will not achieve the same result as handcrafting each icon file, as Visual Studio will have to scale your image to create the required image sizes.

Launching the Manifest Designer

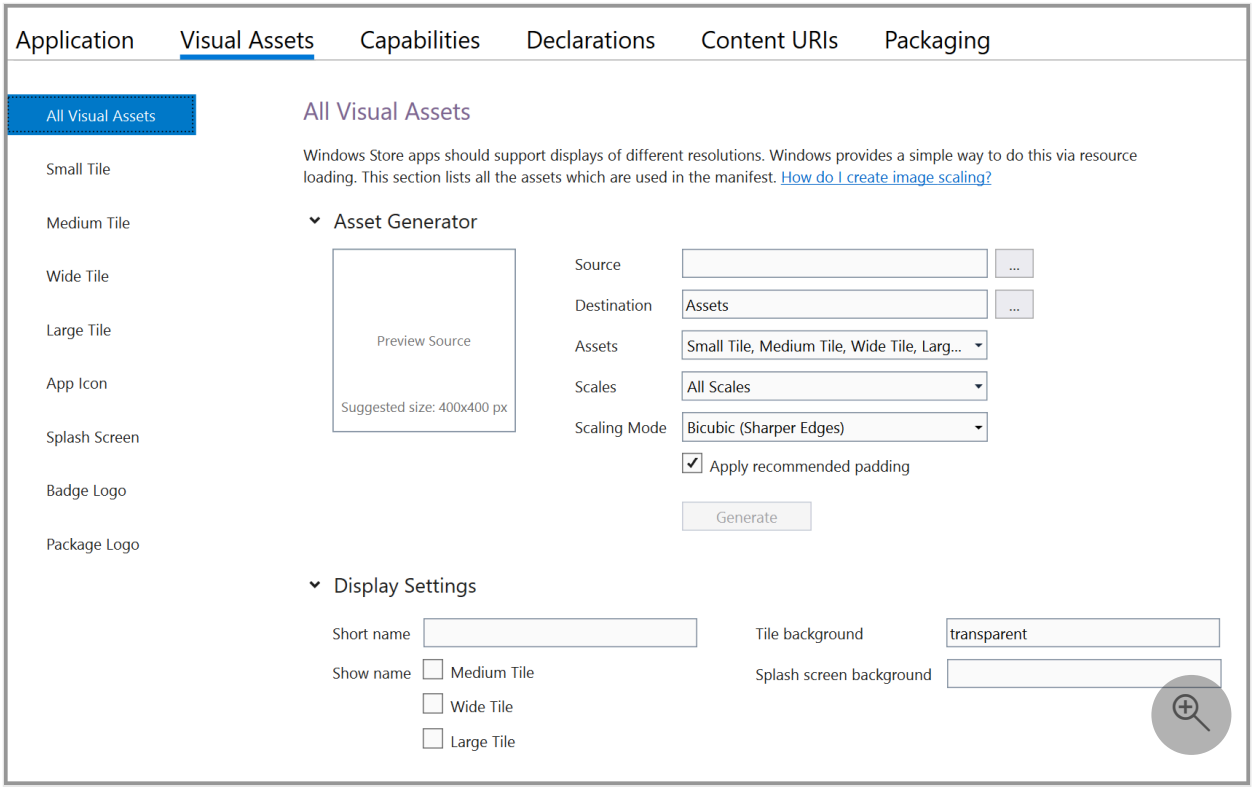
1. Use Visual Studio to open a WinUI or UWP project.
2. In the **Solution Explorer**, double-click the Package.appxmanifest file.



3. Visual Studio displays the Manifest Designer.



4. Click the **Visual Assets** tab.



Generating icons with the Manifest Designer

1. Click the `...` next to the Source field and select the image you want to use. For best results, use a vector-based image, Adobe Illustrator file, or PDF. If you're using a bitmap image, make sure it's at least 400 by 400 pixels so that you get sharp results.

2. In the Display Settings section, configure these options:

    - **Short name**: Specify a short name for your app.
    - **Show name**: Indicate whether you want to display the short name on medium, wide, or large tiles.
    - **Tile background**: Specify the hex value or a color name for the tile background color. For example, #464646. The default value is transparent. **NOTE:** This setting will be ignored on versions of Windows that support theme-aware Live Tiles.
    - **Splash screen background** (Optional): Specify the hex value or color name for the splash screen background.

3. Click **Generate**.

> **Note**
>
> Visual Studio's Manifest Designer doesn't generate a badge logo by default. That's because your badge logo is unique and probably shouldn't match your other app icons. For more info, see Badge notifications for Windows apps.

Segoe MDL2 Assets icons

Article • 07/18/2024

This article provides developer guidelines for using the Segoe MDL2 Assets icons and lists the font glyphs along with their unicode values and descriptive names.

Important APIs:

- FontIcon class

About Segoe MDL2 Assets

> **ⓘ Important**
>
> With the release of Windows 10, the `Segoe MDL2 Assets` font replaced the Windows 8/8.1 `Segoe UI Symbol` icon font.
>
> With the release of Windows 11, the **`Segoe Fluent Icons`** font replaced `Segoe MDL2 Assets` as the recommended symbol icon font. `Segoe UI Symbol` and `Segoe MDL2 Assets` are still available, but we recommend updating your app to use the Segoe Fluent Icons font.

Most of the icons included in the `Segoe MDL2 Assets` font are mapped to the Private Use Area of Unicode (PUA). The PUA allows font developers to assign private Unicode values to glyphs that don't map to existing code points. This is useful when creating a symbol font, but it creates an interoperability problem. If the font is not available, the glyphs won't show up. Use these glyphs only when you can explicitly specify the `Segoe MDL2 Assets` font. If you are working with tiles, you can't use these glyphs because you can't specify the tile font and PUA glyphs are not available via font-fallback.

Unlike with `Segoe UI Symbol`, the icons in the `Segoe MDL2 Assets` font are not intended for use in-line with text. This means that some older "tricks" like the progressive disclosure arrows no longer apply. Likewise, since all of the new icons are sized and positioned the same, they do not have to be made with zero width; we have just made sure they work as a set. Ideally, you can overlay two icons that were designed as a set and they will fall into place. We may do this to allow colorization in the code. For example, U+EA3A and U+EA3B were created for the Start tile Badge status. Because these are already centered the circle fill can be colored for different states.

Layering and mirroring

All glyphs in `Segoe MDL2 Assets` have the same fixed width with a consistent height and left origin point, so layering and colorization effects can be achieved by drawing glyphs directly on top of each other. This example show a black outline drawn on top of the zero-width red heart.

Many of the icons also have mirrored forms available for use in languages that use right-to-left text directionality such as Arabic, Dari, Persian, and Hebrew.

Using the icons

To use a glyph from the `Segoe MDL2 Assets` font, then use a **FontIcon**.

XAML

```
<FontIcon FontFamily="Segoe MDL2 Assets" Glyph="&#xE700;"/>
```

How do I get this font?

- On Windows: There's nothing you need to do, the font comes with Windows.
- On a Mac, you need to download and install the font: Get the Segoe UI and MDL2 icon fonts

Icon list

Please keep in mind that the `Segoe MDL2 Assets` font includes many more icons than we can show here. Many of the icons are intended for specialized purposes and are not typically used anywhere else.

> **Note**
>
> Glyphs with prefixes ranging from **E0-** to **E5-** (e.g. E001, E5B1) are currently marked as legacy and we recommend that they not be used.

The following tables display all Segoe MDL2 Assets icons and their respective unicode values and descriptive names. Select a range from the following list to view glyphs

according to the PUA range they belong to.

- PUA E700-E900
- PUA EA00-EC00
- PUA ED00-EF00
- PUA F000-F200
- PUA F300-F500
- PUA F600-F800

PUA E700-E900

The following table of glyphs displays unicode points prefixed from E7- to E9-.

Segoe Fluent Icons font

Article • 12/09/2024

This article provides developer guidelines for using the Segoe Fluent Icons font and lists each icon along with its Unicode value and descriptive name.

Important APIs:

- FontIcon class

About Segoe Fluent Icons

> **Tip**
>
> With the release of Windows 11, the **`Segoe Fluent Icons`** font replaced `Segoe MDL2 Assets` as the recommended symbol icon font. `Segoe MDL2 Assets` is still available, but we recommend updating your app to use the `Segoe Fluent Icons` font.

Most of the icons included in the `Segoe Fluent Icons` font are mapped to the Private Use Area of Unicode (PUA). The PUA range is a non-standardized range of Unicode that allows font developers to define their own characters. This is useful when creating a symbol font, but it creates an interoperability problem when `Segoe Fluent Icons` is not available.

Icons in the `Segoe Fluent Icons` font are not intended for use in-line with text. This means that some older "tricks" like the progressive disclosure arrows no longer apply. Likewise, since all of the new icons are sized and positioned the same, they do not have to be made with zero width; we have made sure they work as a set.

Layering and mirroring

All glyphs in `Segoe Fluent Icons` have the same fixed width with a consistent height and left origin point, so layering and colorization effects can be achieved by drawing glyphs directly on top of each other. This example show a black outline drawn on top of the zero-width red heart.

XAML

```
<Grid>
    <FontIcon FontFamily="Segoe Fluent Icons" Glyph="&#xEB52;"
              Foreground="#C72335" />
    <FontIcon FontFamily="Segoe Fluent Icons" Glyph="&#xEB51;" />
</Grid>
```

Many of the icons also have mirrored forms available for use in languages that use right-to-left text directionality such as Arabic, Dari, Persian, and Hebrew.

Using the icons

If you are developing an app in XAML, you can use specified glyphs from `Segoe Fluent Icons` with a SymbolIcon and the Symbol enumeration.

XAML

```
<SymbolIcon Symbol="GlobalNavigationButton"/>
```

If you would like to use a glyph from the `Segoe Fluent Icons` font that is not included in the Symbol enum, set it as the Glyph property of a **FontIcon** control.

XAML

```
<FontIcon FontFamily="Segoe Fluent Icons" Glyph="&#xE700;"/>
```

You can also use the static resource `SymbolThemeFontFamily` to access `Segoe Fluent Icons`, instead of specifying the font by name:

XAML

```
<FontIcon FontFamily="{StaticResource SymbolThemeFontFamily}"
Glyph="&#xE700;"/>
```

> **Note**
>
> For optimal appearance, use these specific sizes: 16, 20, 24, 32, 40, 48, and 64. Deviating from these font sizes could lead to less crisp or blurry outcomes.

How do I get this font?

- On Windows 11: There's nothing you need to do, the font comes with Windows.
- On Windows 10: `Segoe Fluent Icons` is not included by default on Windows 10. You can download it here.
- On a Mac or other device: You can download `Segoe Fluent Icons` and other fonts here. You can download the font for use in design and development, but you may not ship it to another platform.

Examples

Open the WinUI 3 Gallery app and see Iconography principles in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

Icon list

Please keep in mind that the `Segoe Fluent Icons` font includes many more icons than we can show here. Many of the icons are intended for specialized purposes and are not typically used anywhere else.

> ⓘ **Note**
>
> Glyphs with prefixes ranging from **E0-** to **E5-** (e.g. E001, E5B1) are currently marked as legacy and are therefore deprecated.

The following tables display all `Segoe Fluent Icons` glyphs and their respective unicode values and descriptive names. Select a range from the following list to view glyphs according to the PUA range they belong to.

- PUA E700-E900
- PUA EA00-EC00
- PUA ED00-EF00
- PUA F000-F200
- PUA F300-F500

Layout

Article • 11/26/2024

These articles help you create a flexible UI that looks great on different screen sizes, window sizes, resolutions, and orientations.

App silhouettes

Learn about common layout patterns.

App title bar

Learn about design recommendations and behaviors of the parts of a standard title bar.

Screen sizes and breakpoints

Learn about screen sizes across the Windows ecosystem and how to design for breakpoints.

Responsive design techniques

Learn about responsive design techniques that optimize your app's layout for breakpoints.

Layouts with XAML

Implement responsive UI in XAML with adaptive or tailored layouts.

Layout panels

Learn about each type of layout panel and how to use them to arrange UI elements.

Alignment, margin, padding

Use alignment, margin, and padding to influence layout behavior.

Spacing

Use sizing to provide a balance between information density and user comfort.

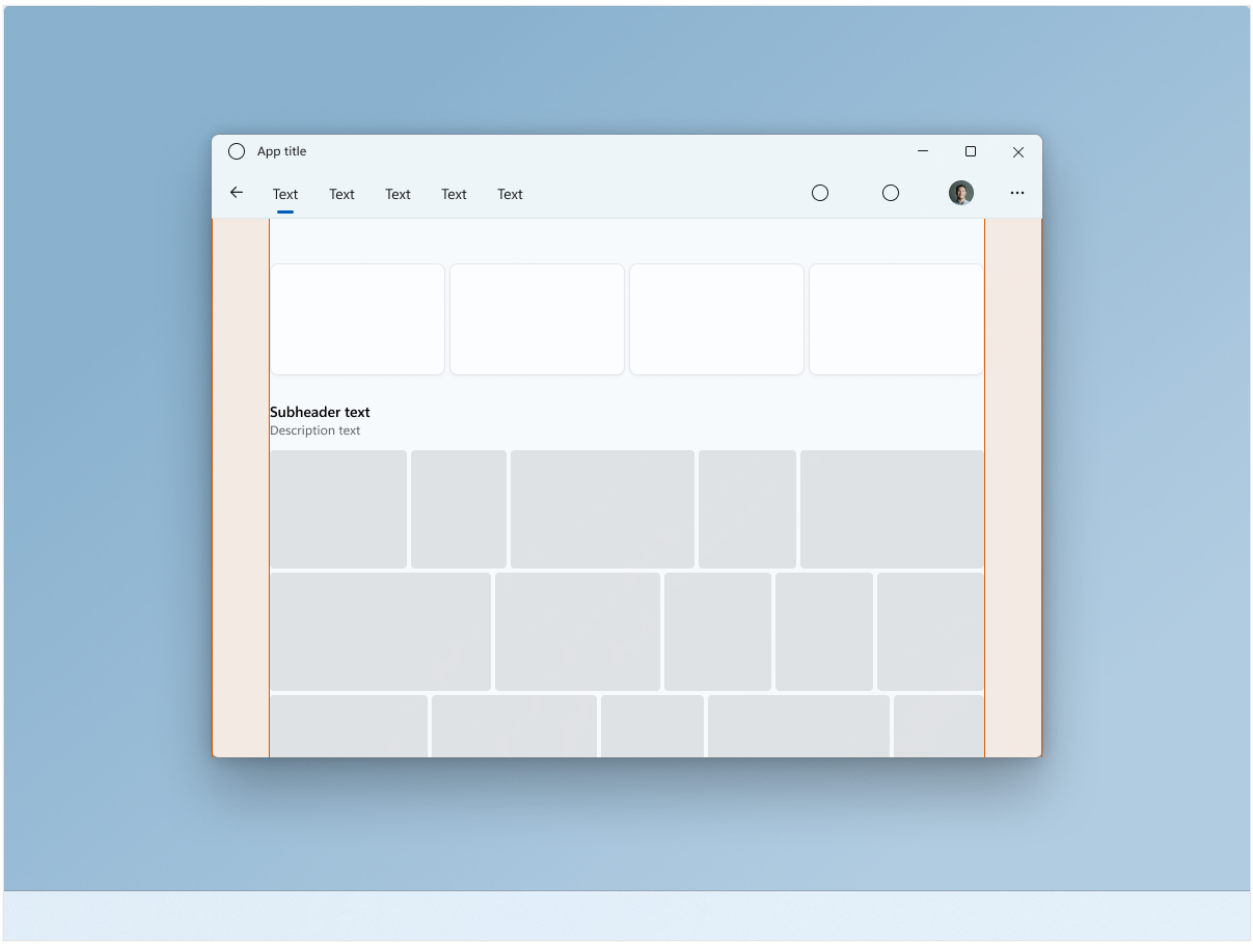
Windows app silhouettes

Article • 10/24/2022

Silhouettes indicate a common pattern of relationships between elements such as app layering, menus, navigation, commanding and content areas. This article focuses on the common silhouettes as used in several Windows in-box apps.

Also refer to Content Basics for common arrangements of content and controls.

Top navigation silhouette



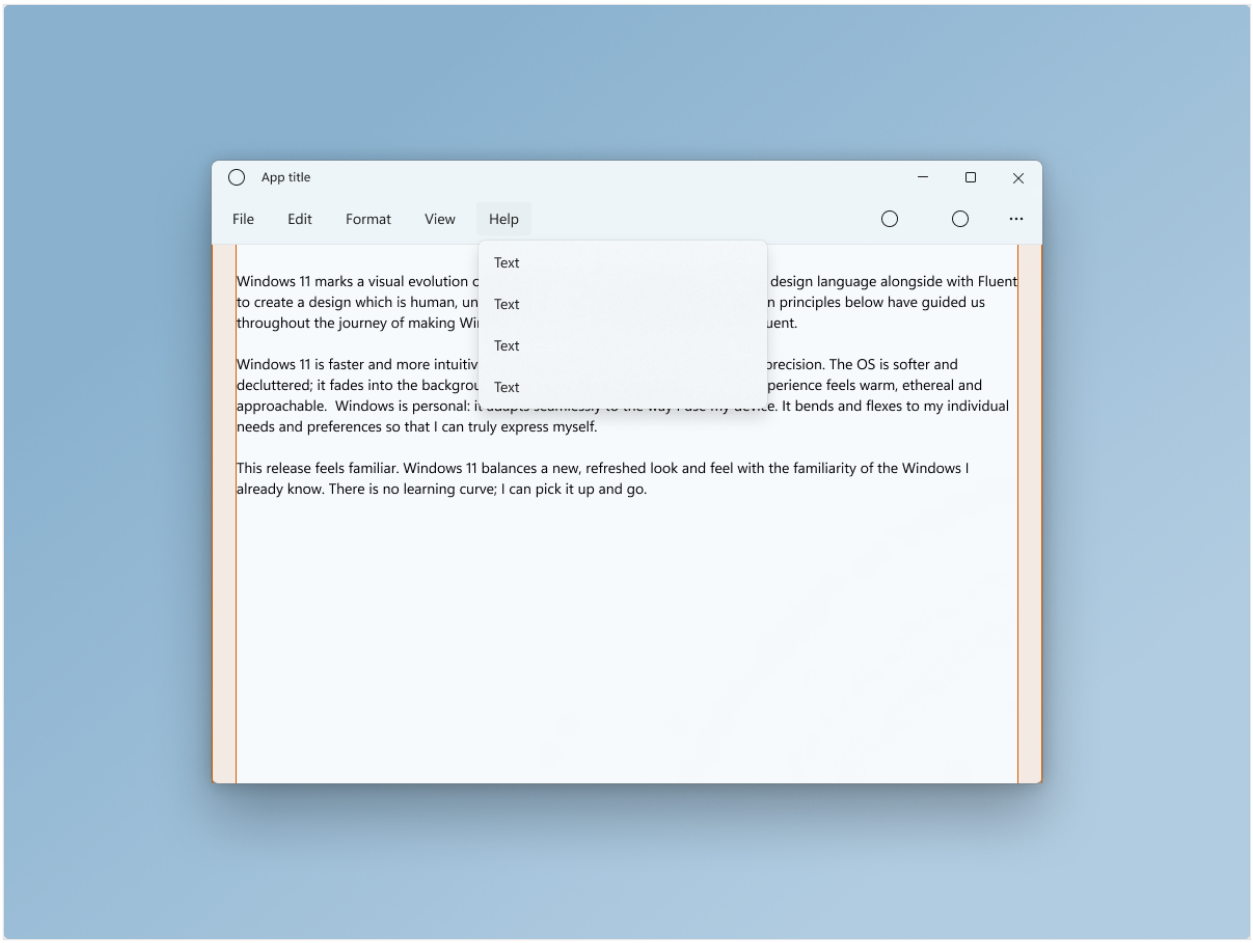
A NavigationView can be used at the top of the app's content layer, building a connection with the content below. Note the location of user identity/person/picture control when using top navigation.

Placing navigation on the same row as commands can be useful when trying to maximize the amount of vertical space for the content below.

Content margins can vary. This example uses 56epx margins, complementing large pieces of media. Use smaller margins for smaller/tighter content needs.

In Windows 11, Photos is a good example of an app that uses a top navigation silhouette.

Menu bar silhouette

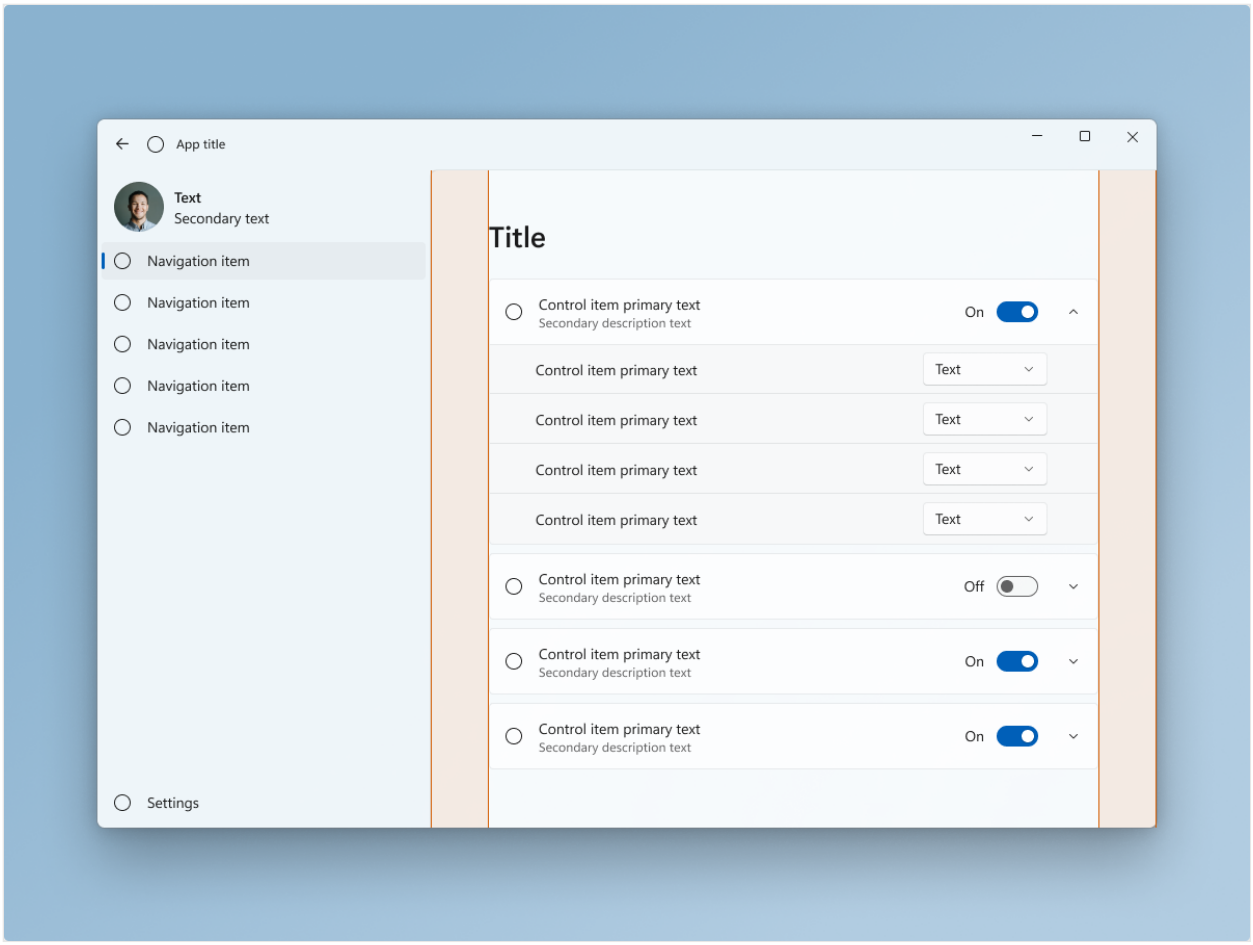


A MenuBar can be used as part of the of the base layer along with a CommandBar. This brings more focus to the content area's primary task, in this case composition and editing.

This example depicts a text editor using 12epx margins to compliment the utility of the app.

In Windows 11, Notepad is a good example of an app that uses a menu bar silhouette.

Left navigation silhouette

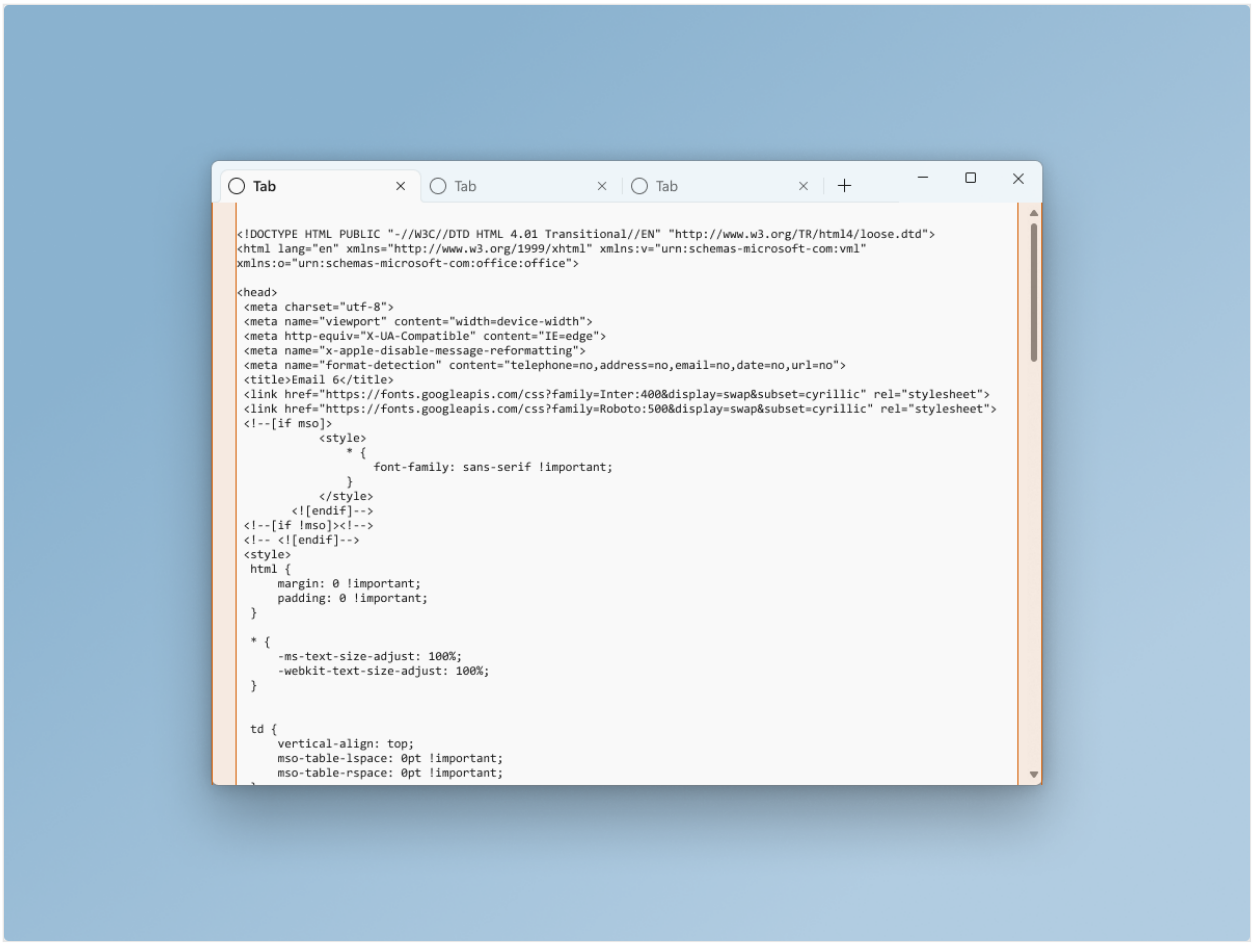


NavigationView controls automatically rests on the app's base layer. This brings more focus to the content area's primary task. Note the location of user identity/person/picture control when using left navigation.

Content margins can vary. This example uses 56epx margins to compliment the cohesion of the content within the expanders. Use smaller margins when content cohesion is less of a concern, because other design elements reinforce cohesion, content is not nested in expanders, or content should not logically be grouped together.

In Windows 11, Settings is a good example of an app that uses a left navigation silhouette.

Tab View Silhouette



A TabView can integrate with the app's base layer, and title barcontrol. This brings more focus to the content area's primary task, in this case code composition and editing.

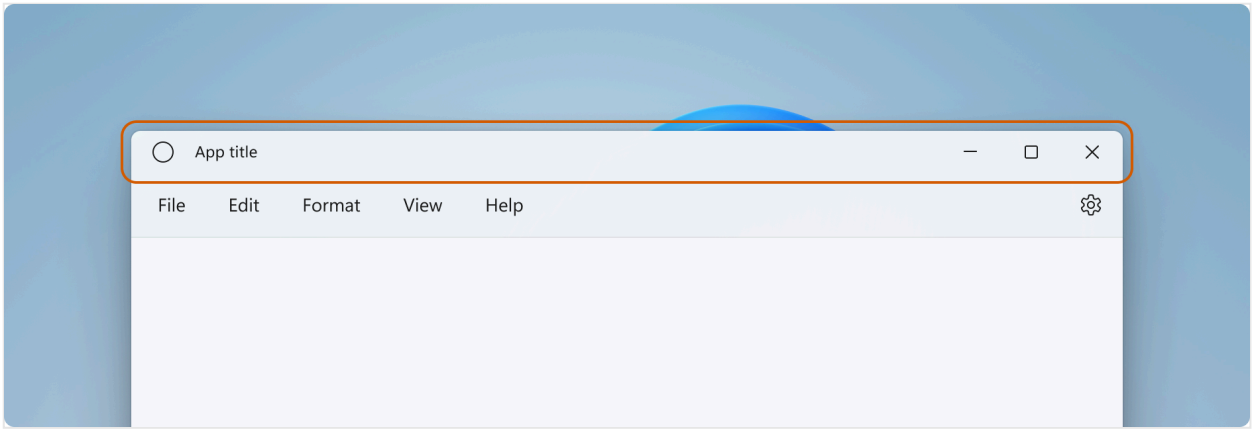
This example depicts a text editor using 12epx margins to compliment the utility of the app.

In Windows 11, Terminal is a good example of an app that uses a tab view silhouette.

Title bar design

Article • 07/31/2024

The title bar sits at the top of an app on the base layer. Its main purpose is to allow users to be able to identify the app via its title, move the app window, and minimize, maximize, or close the app.



Standard design

This section describes the design recommendations and behaviors of the parts of a standard title bar.

Bar

Design

- The standard title bar has a height of 32px.
- The title bar's default background is Mica, however we recommend that title bars blend with the rest of the window if possible.
- Title bars help users differentiate when a window is active and inactive. All title bar elements should be semi-transparent when the window is inactive.
- The title bar colors should adjust when users switch to high contrast themes, or between light and dark modes.
  - For high contrast themes, apps should use the `SystemColors` class for determining proper UI element coloring to facilitate a superior high-contrast experience.

Behavior

- The title bar plays a vital role in repositioning and resizing a window. All empty space in the title bar or space taken up by non-interactive elements like the

window title should be draggable.
- A right-click/press-and-hold on any part of the title bar that does not have an interactive element should show the system window menu.
- A double-click/tap should toggle between maximizing the window and restoring the window.

Icon

Design

- The size of the window icon is 16px by 16px.
- Place the icon 16px from the left-most border in LTR, or right-most border in RTL.
  - If the back button is present, place the window icon 16px to the right of the back button.
- The window icon should be vertically centered in the title bar. For example, When the title bar height is 32px, the top and bottom margins are 8px.

Behavior

- A single-click/tap on the icon should show system window menu.
- A double-click/tap should close the window.

Title

Design

- Place the window title 16px from the window icon or back button.
  - If neither an icon nor back button are present, place the window title 16px from the left-most border in LTR, or right-most border in RTL.
- The window title should use the Segoe UI Variable (if available) or Segoe UI font.
- The window title should use *caption* style text (see XAML type ramp).
- The window title can be truncated, and an ellipsis added if the window width is smaller than the length of the title bar elements. The icon and caption buttons (min, max and close) should always be fully visible.

Behavior

- A right-click/press-and-hold on the icon should show the system window menu.
- A double-click/tap should toggle between maximizing the window and restoring the window.
- The window title and other textual elements in the title bar should respond to text-scaling. This might require that the title bar grows in height.

Caption controls (minimize, maximize, restore, close)

If you create your own caption buttons for your app, follow these guidelines to match the system caption buttons.

Design

- Use these icons for the buttons:
  - Minimize icon: E921 ChromeMinimize
  - Maximize icon: E922 ChromeMaximize
  - Restore icon: E923 ChromeRestore
  - Close icon: E8BB ChromeClose
- The icons for the maximize and restore buttons have rounded corners.
- Caption buttons have full bleed backplates.
- Caption buttons respond to *rest*, *on hover*, *on pressed*, *active*, and *inactive* states.

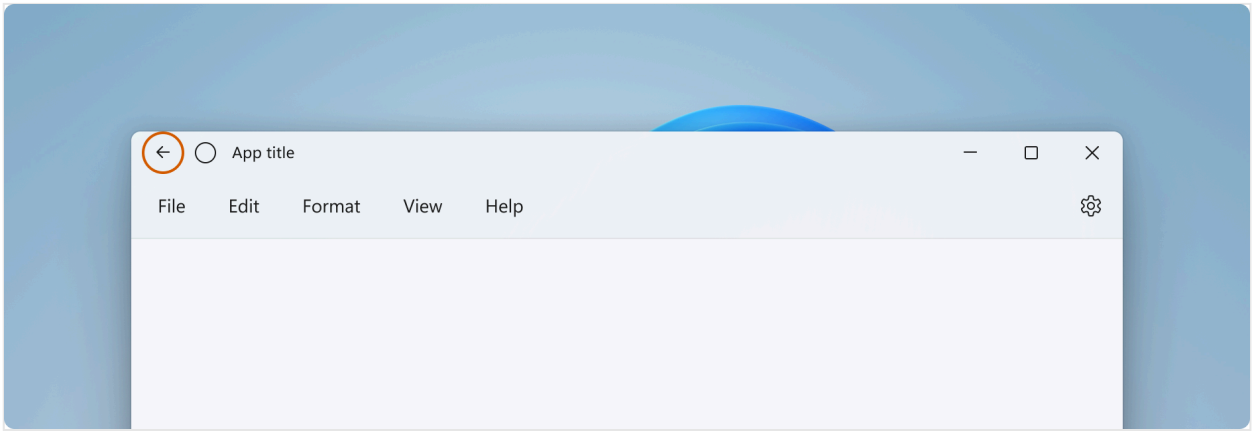
Additional design patterns

Back button

Design

The recommended back button icon is: E830 ChromeBack

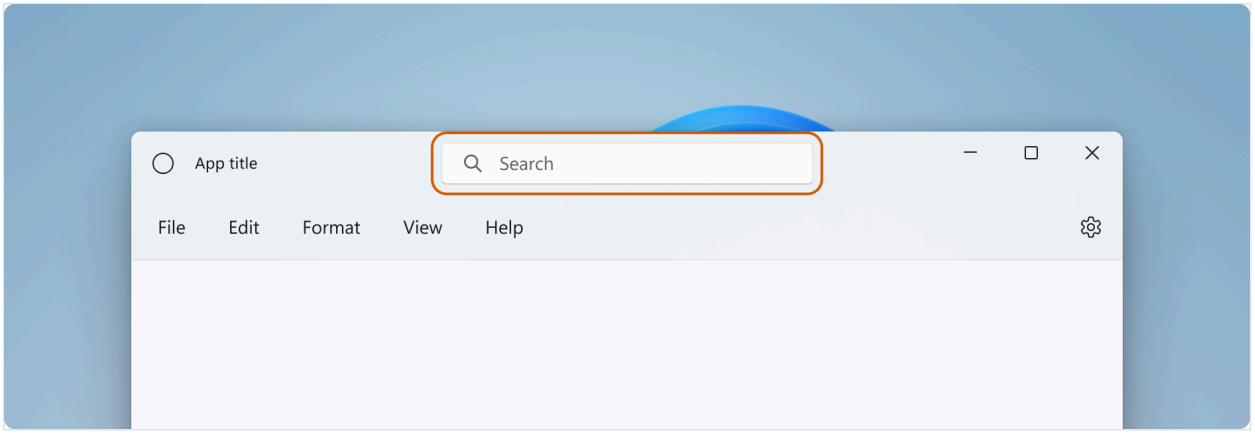
- If a back button is present, it should be placed to the left of the app title or icon/title combination (in LTR).
- The back button responds to *rest*, *on hover*, *on pressed*, *active*, and *inactive* states.
- The back button should be 16px by 16px and vertically centered in the title bar. The button should have a full bleed backplate.
- The back button should be 16px from the left-most border in LTR, or right-most border in RTL, and 16px from the next element to the left or right of it.



Search

Design

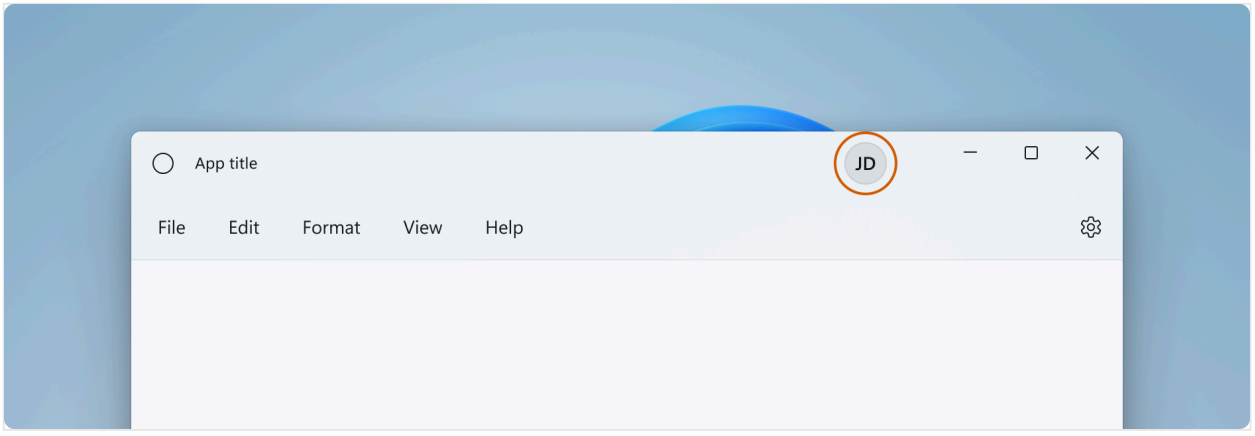
If global search functionality is present, a searchbox should be added to the title bar, centered to the window. Increase the size of the title bar to 48px when you include a searchbox.



The search box needs to be responsive to react to window size changes.

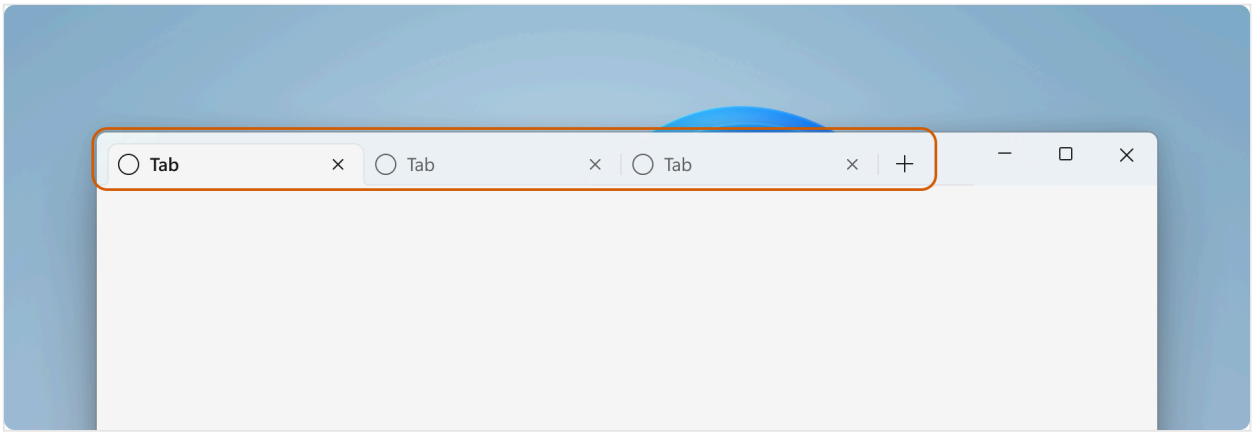
People

If account representation is present, the person-picture control should be placed to the left of the caption controls. Increase the size of the title bar to 48px when you include a person-picture.



Tabs

If you use tabs as the main element of your app, use the title bar space and keep caption controls anchored to the right.



Next steps

See the developer guidance for title bar

Control size and density

Article • 01/22/2025

Use a combination of control size and density to optimize your Windows application and provide a user experience that is most appropriate for your app's functionality and interaction requirements.

By default, XAML apps are rendered with a low-density (or `Standard`) layout. However, beginning with WinUI 2.1, a high-density (or `Compact`) layout option, for information rich UI and similar specialized scenarios, is also supported. This can be specified through a basic style resource (see examples below).

While functionality and behavior has not changed and remains consistent across the two size and density options, the default body font size has been updated to 14px for all controls to support these two density options. This font size works across regions and devices and ensures your application remains balanced and comfortable for users.

Examples

Open the WinUI 3 Gallery app and see Spacing examples

Open the WinUI 3 Gallery app and see Compact Sizing in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

Fluent Standard sizing

Fluent Standard sizing was created to provide a balance between information density and user comfort. Effectively, all items on the screen align to a 40x40 effective pixels (epx) target, which lets UI elements align to a grid and scale appropriately based on system level scaling.

Standard sizing is designed to accommodate both touch and pointer input.

> **Note**
>
> For more info on effective pixels and scaling, see Screen sizes and breakpoints

For more info on system level scaling, see Alignment, margin, padding.

Fluent Compact sizing

Compact sizing enables dense, information-rich groups of controls and can help with the following:

- Browsing large amounts of content.
- Maximizing visible content on a page.
- Navigating and interacting with controls and content

Compact sizing is designed primarily to accommodate pointer input.

Examples of compact sizing

Compact sizing is implemented through a special resource dictionary that can be specified in your application at either the page level or on a specific layout. The resource dictionary is available in the WinUI Nuget package.

The following examples show how the `Compact` style can be applied for the page and an individual Grid control.

Page level

XAML

```
<Page.Resources>
    <ResourceDictionary
        Source="ms-appx:///Microsoft.UI.Xaml/DensityStyles/Compact.xaml"/>
</Page.Resources>
```

Grid level

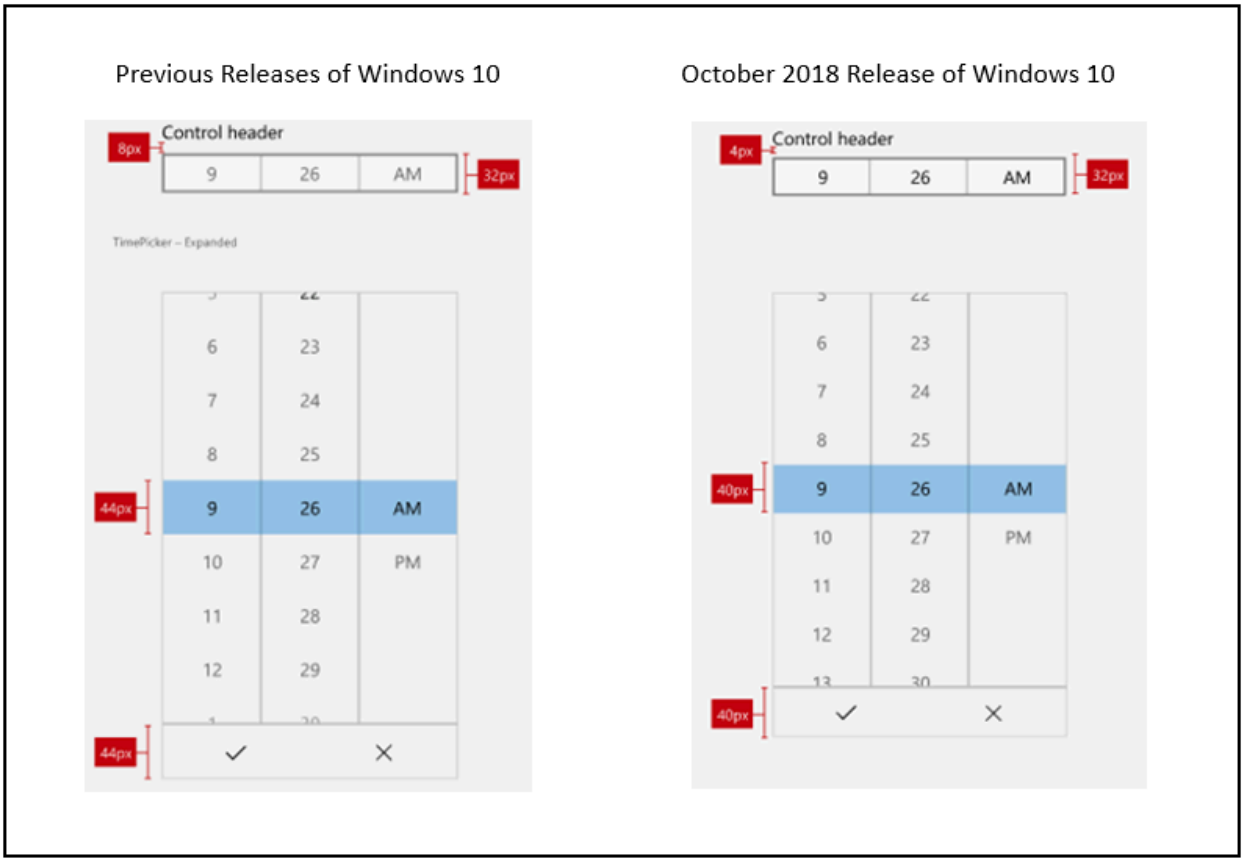
XAML

```
<Grid>
    <Grid.Resources>
        <ResourceDictionary
           Source="ms-
appx:///Microsoft.UI.Xaml/DensityStyles/Compact.xaml"/>
    </Grid.Resources>
</Grid>
```

Sizing in Windows apps

In the Windows 10 October 2018 Update (version 1809 and later), the standard, default size for all Windows XAML controls was decreased to increase usability across all usage scenarios.

The following image shows some of the control layout changes that were introduced with the Windows 10 October 2018 Update. Specifically, the margin between a header and the top of a control was decreased from 8epx to 4epx, and the 44epx grid was changed to a 40epx grid.



This next image shows the changes made to control sizes for the Windows 10 October 2018 Update. Specifically, alignment to the 40epx grid.

Screen sizes and breakpoints

Article • 11/21/2024

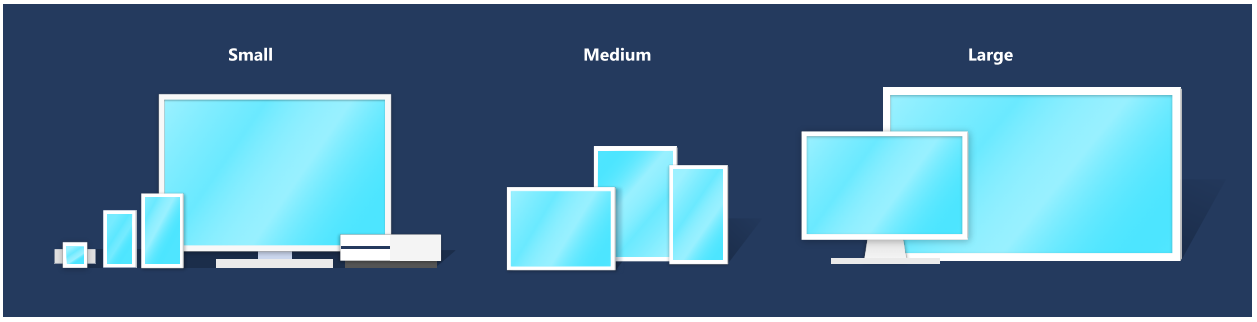
Windows apps can run on any device running Windows, which includes tablets, desktops, TVs, and more. With a huge number of device targets and screen sizes across the Windows ecosystem, rather than optimizing your UI for each device, we recommended designing for a few key width categories (also called "breakpoints"):

- Small (smaller than 640px)
- Medium (641px to 1007px)
- Large (1008px and larger)

> **Tip**
>
> When designing for specific breakpoints, design for the amount of screen space available to your app (the app's window), not the screen size. When the app is running full-screen, the app window is the same size as the screen, but when the app is not full-screen, the window is smaller than the screen.

Breakpoints

This table describes the different size classes and breakpoints.



Expand table

Size class	Breakpoints	Typical screen size	Devices	Window Sizes
Small	up to 640px	20" to 65"	TVs	320x569, 360x640, 480x854
Medium	641 - 1007px	7" to 12"	Tablets	960x540

Size class	Breakpoints	Typical screen size	Devices	Window Sizes
Large	1008px and up	13" and up	PCs, Laptops, Surface Hub	1024x640, 1366x768, 1920x1080

Why are TVs considered "small"?

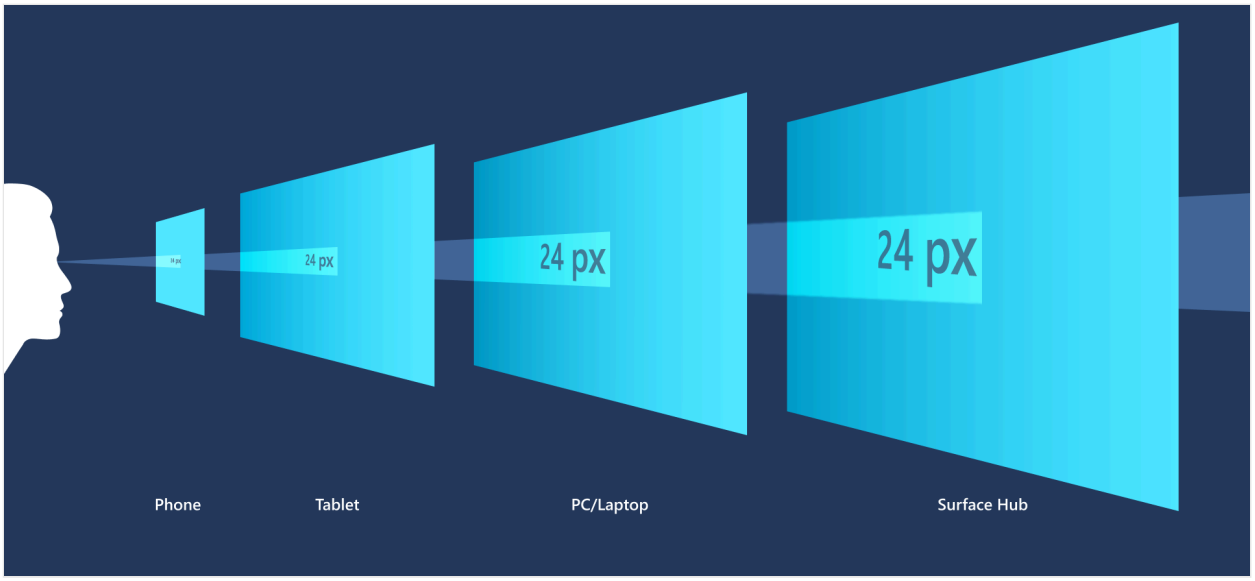
While most TVs are physically quite large (40 to 65 inches is common) and have high resolutions (HD or 4k), designing for a 1080P TV that you view from 10 feet away is different from designing for a 1080p monitor sitting a foot away on your desk. When you account for distance, the TV's 1080 pixels are more like a 540-pixel monitor that's much closer.

XAML's effective pixel system automatically takes viewing distance in account for you. When you specify a size for a control or a breakpoint range, you're actually using "effective" pixels. For example, if you create responsive code for 1080 pixels or more, a 1080 monitor will use that code, but a 1080p TV will not--because although a 1080p TV has 1080 physical pixels, it only has 540 effective pixels. Which makes designing for a TV similar to designing for a small screen.

Effective pixels and scale factor

XAML helps by automatically adjusting UI elements so that they're legible and easy to interact with on all devices and screen sizes.

When your app runs on a device, the system uses an algorithm to normalize the way UI elements display on the screen. This scaling algorithm takes into account viewing distance and screen density (pixels per inch) to optimize for perceived size (rather than physical size). The scaling algorithm ensures that a 24 px font on a large presentation screen 10 feet away is just as legible to the user as a 24 px font on a small portable screen that's a few inches away.

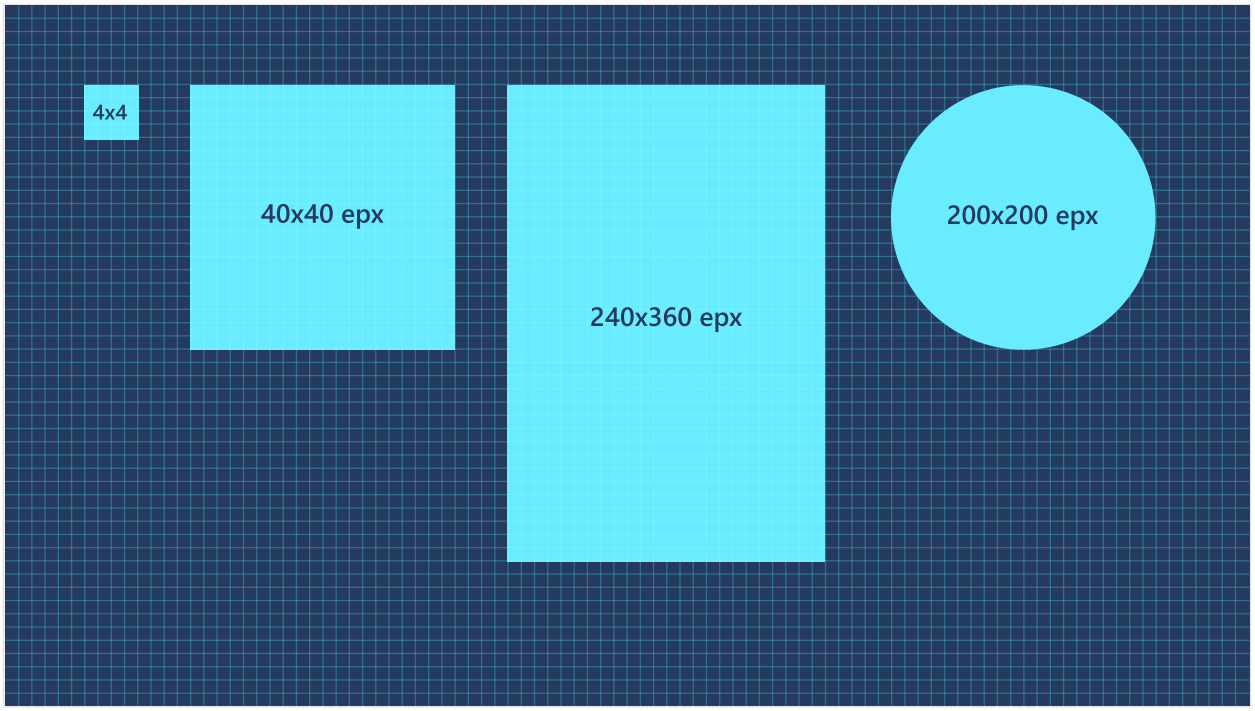


Because of how the scaling system works, when you design your XAML app, you're designing in effective pixels, not actual physical pixels. Effective pixels (epx) are a virtual unit of measurement, and they're used to express layout dimensions and spacing, independent of screen density. (In our guidelines, epx, ep, and px are used interchangeably.)

You can ignore the pixel density and the actual screen resolution when designing. Instead, design for the effective resolution (the resolution in effective pixels) for a size class.

> **Tip**
>
> When creating screen mockups in image editing programs, set the DPI to 72 and set the image dimensions to the effective resolution for the size class you're targeting.

Multiples of Four



The sizes, margins, and positions of UI elements should always be in multiples of 4 epx in your XAML apps.

XAML scales across a range of devices with scaling plateaus of 100%, 125%, 150%, 175%, 200%, 225%, 250%, 300%, 350%, and 400%. The base unit is 4 because it can be scaled to these plateaus as a whole number (for example; 4 x 125% = 5, 4 x 150% = 6). Using multiples of four aligns all UI elements with whole pixels and ensures UI elements have crisp, sharp edges. (Note that text doesn't have this requirement; text can have any size and position.)

Responsive design techniques

Article • 11/05/2024

Responsive design uses just one layout where the content is fluid and can adapt to changing window sizes. Responsive design lets you build a feature one time and expect it to work across all screen sizes. *Adaptive* design is similar, but replaces one layout with another layout.

XAML apps use effective pixels to guarantee that your UI will be legible and usable on all Windows-powered devices. So, why would you ever want to customize your app's UI for a specific device or screen size?

- **To make the most effective use of space and reduce the need to navigate**

  If you design an app to look good on a device that has a small screen, such as a tablet, the app will be usable on a PC with a much bigger display, but there will probably be some wasted space. You can customize the app to display more content when the screen is above a certain size. For example, a shopping app might display one merchandise category at a time on a tablet, but show multiple categories and products simultaneously on a PC or laptop.

  By putting more content on the screen, you reduce the amount of navigation that the user needs to perform.

- **To take advantage of devices' capabilities**

  Certain devices are more likely to have certain device capabilities. For example, laptops are likely to have a location sensor and a camera, while a TV might not have either. Your app can detect which capabilities are available and enable features that use them.

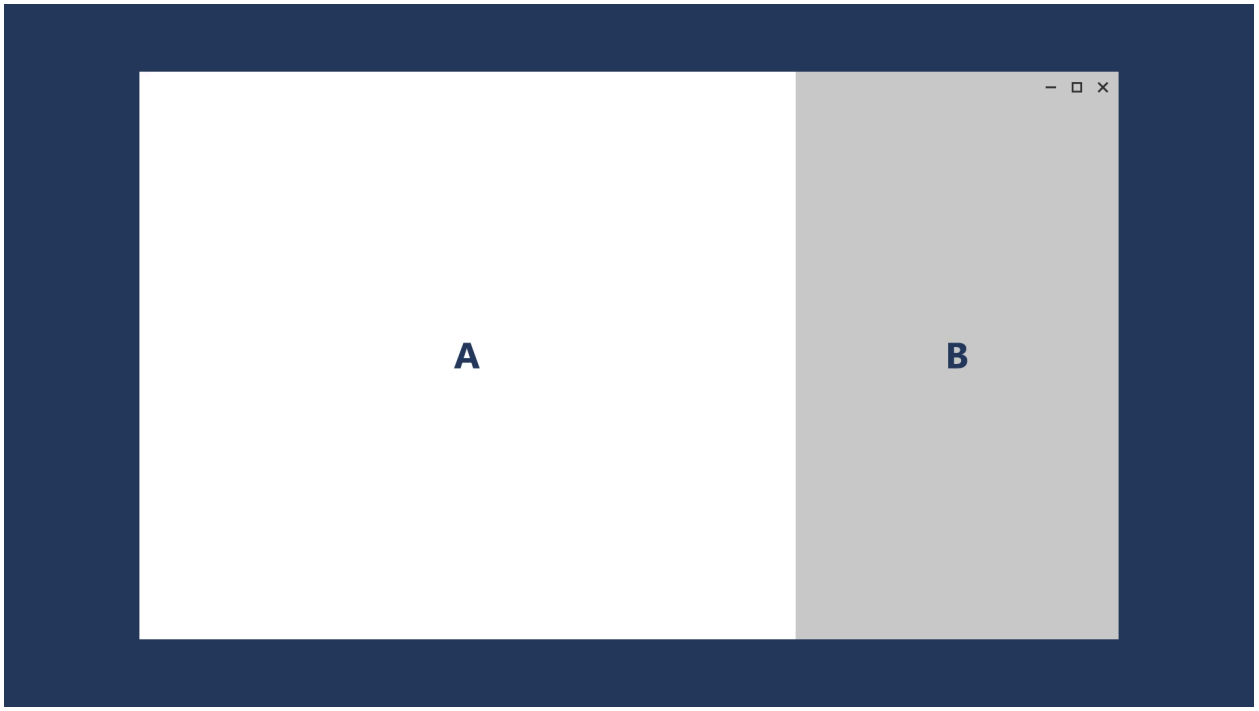
- **To optimize for input**

  The universal control library works with all input types (touch, pen, keyboard, mouse), but you can still optimize for certain input types by re-arranging your UI elements.

When you optimize your app's UI for specific screen widths, we say that you're creating a responsive design. Here are some responsive design techniques you can use to customize your app's UI.

Reposition

You can alter the location and position of UI elements to make the most of the window size. In this example, the smaller window stacks elements vertically. When the app translates to a larger window, elements can take advantage of the wider window width.



In this example design for a photo app, the photo app repositions its content on larger screens.

Resize

You can optimize for the window size by adjusting the margins and size of UI elements. For example, this could augment the reading experience on a larger screen by simply growing the content frame.

Reflow

By changing the flow of UI elements based on device and orientation, your app can offer an optimal display of content. For instance, when going to a larger screen, it might make sense to add columns, use larger containers, or generate list items in a different way.

This example shows how a single column of vertically scrolling content on a smaller screen that can be reflowed on a larger screen to display two columns of text.

Show/hide

You can show or hide UI elements based on screen real estate, or when the device supports additional functionality, specific situations, or preferred screen orientations.

For example, media player controls reduce the button set on smaller screens and expand on larger screens. The media player on a larger window can handle far more on-screen functionality than it can on a smaller window.

Part of the reveal-or-hide technique includes choosing when to display more metadata. With smaller windows, it's best to show a minimal amount of metadata. With larger windows, a significant amount of metadata can be surfaced. Some examples of when to show or hide metadata include:

- In an email app, you can display the user's avatar.
- In a music app, you can display more info about an album or artist.
- In a video app, you can display more info about a film or a show, such as showing cast and crew details.
- In any app, you can break apart columns and reveal more details.
- In any app, you can take something that's vertically stacked and lay it out horizontally. When going from a small window to a larger window, stacked list items can change to reveal rows of list items and columns of metadata.

Re-architect

You can collapse or fork the architecture of your app to better target specific devices. In this example, expanding the window shows the entire list/details pattern.

Adaptive layout

An adaptive layout is similar to responsive layout, but entirely replaces UI based on the format it's presented in. Adaptive design has multiple fixed layout sizes and triggers the page to load a given layout based on the available space.

This technique lets you switch the user interface for a specific breakpoints. In this example, the nav pane and its compact, transient UI works well for a smaller screen, but on a larger screen, tabs might be a better choice.

The NavigationView control supports this technique by letting users set the pane position to either top or left.

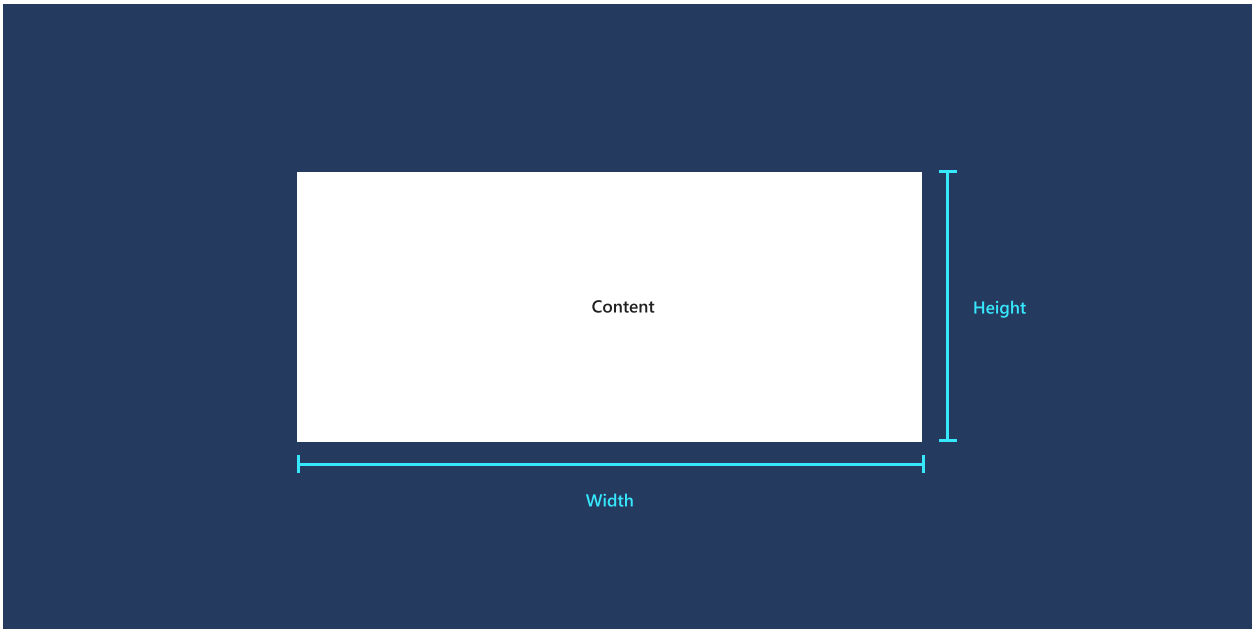
Alignment, margin, padding

Article • 09/26/2024

In XAML apps, most user interface (UI) elements inherit from the **FrameworkElement** class. Every FrameworkElement has dimensions, alignment, margin, and padding properties, which influence layout behavior. The following guidance provides an overview of how to use these layout properties to make sure your app's UI is legible and easy to use in any context.

Dimensions (Height, Width)

Proper sizing ensures all content is clear and legible. Users shouldn't have to scroll or zoom to decipher primary content.

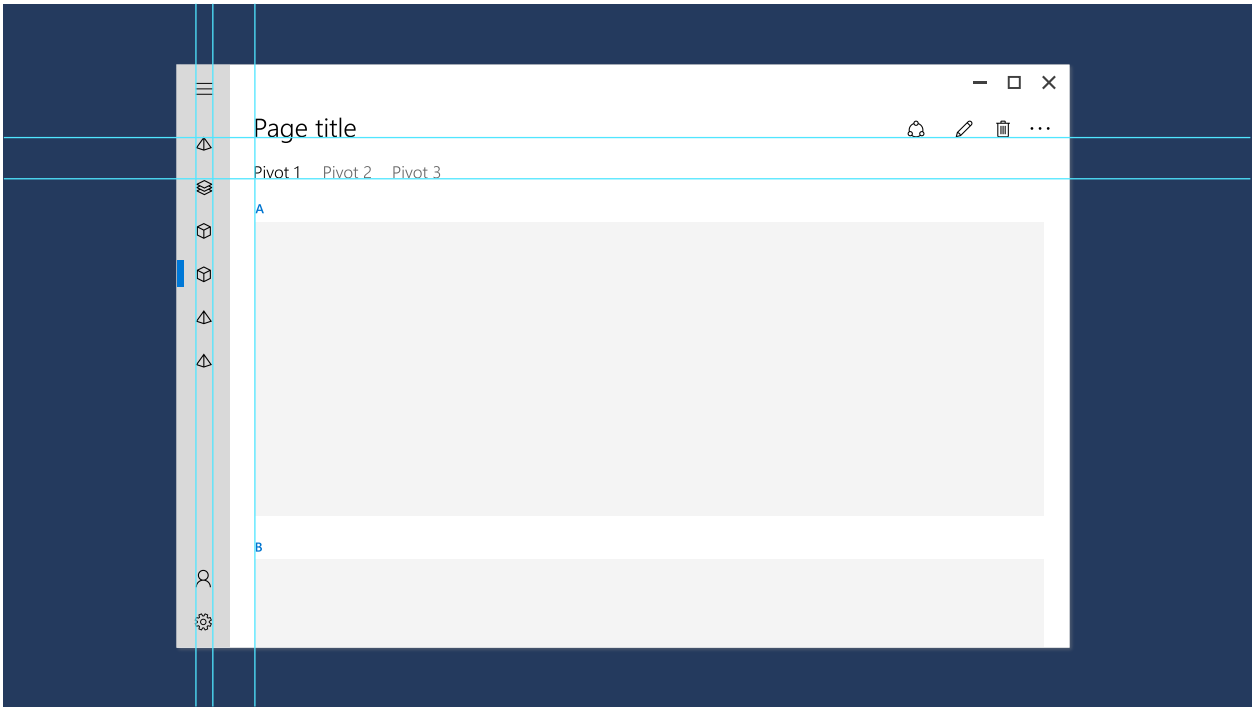


- **Height** and **Width** specify the size of an element. The default values are mathematically `NaN` (Not A Number). You can set fixed values measured in effective pixels, or you can use **Auto** or proportional sizing for fluid behavior.
- **ActualHeight** and **ActualWidth** are read-only properties that provide the size of an element at runtime. If fluid layouts grow or shrink, then the values change in a **SizeChanged** event. Note that a **RenderTransform** will not change the ActualHeight and ActualWidth values.
- **MinWidth**/**MaxWidth** and **MinHeight**/**MaxHeight** specify values that constrain the size of an element while allowing fluid resizing.
- **FontSize** and other text properties control layout size for text elements. While text elements don't have explicitly declared dimensions, they do have calculated

ActualWidth and ActualHeight.

Alignment

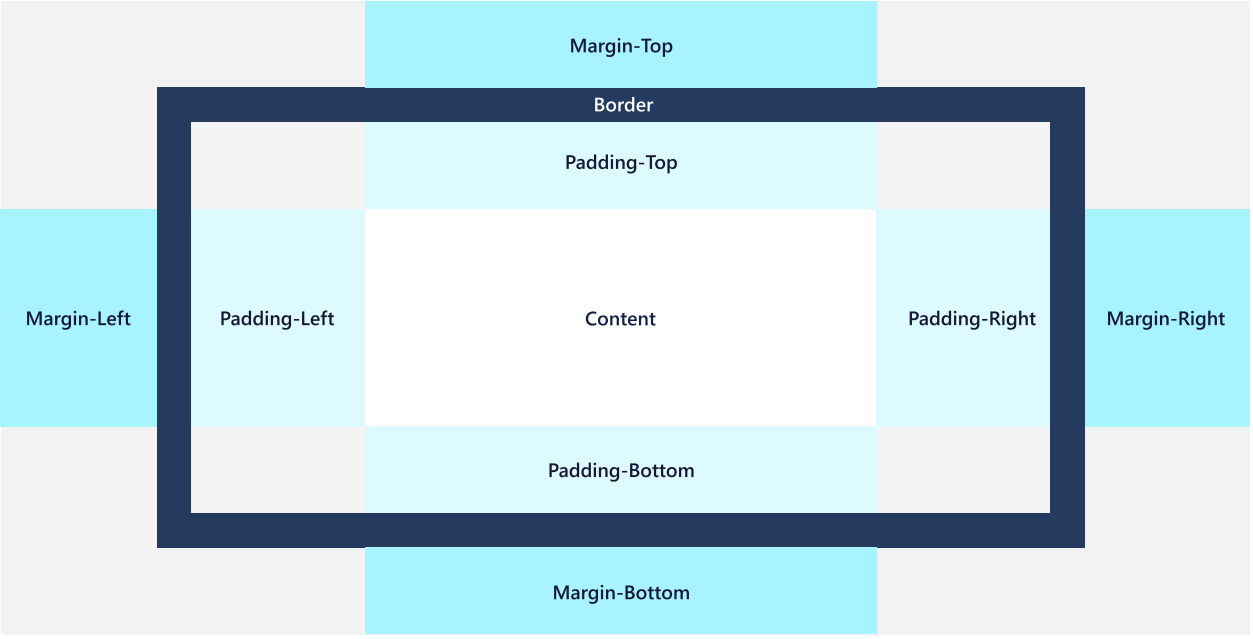
Alignment makes your UI look neat, organized, and balanced and can also be used to establish visual hierarchy and relationships.



- HorizontalAlignment and VerticalAlignment specify how an element should be positioned within its parent container.
  - The values for **HorizontalAlignment** are **Left**, **Center**, **Right**, and **Stretch**.
  - The values for **VerticalAlignment** are **Top**, **Center**, **Bottom**, and **Stretch**.
- **Stretch** is the default for both properties, and elements fill all of the space they're provided in the parent container. Real-number Height and Width cancel a Stretch value, which will instead act as a Center value. Some controls, like Button, override the default Stretch value in their default style.
- HorizontalContentAlignment and VerticalContentAlignment specify how child elements are positioned within a container.
- Alignment can affect clipping within a layout panel. For example, with `HorizontalAlignment="Left"`, the right side of the element gets clipped if the content is larger than the ActualWidth.
- Text elements use the TextAlignment property. Generally, we recommend using left-alignment, the default value. For more information about styling text, see Typography.

Margin and padding

Margin and padding properties keep UI from looking too cluttered or too sparse, and they can also make it easier to use certain inputs like pen and touch. Here's an illustration displaying margins and padding for a container and its content.



Margin

Margin controls the amount of empty space around an element. Margin does not add pixels to ActualHeight and ActualWidth and is not considered part of the element for hit testing and sourcing input events.

- Margin values can be uniform or distinct. With `Margin="20"`, a uniform margin of 20 pixels would be applied to the element on the left, top, right, and bottom sides. With `Margin="0,10,5,25"`, the values are applied to the left, top, right, and bottom (in that order).
- Margins are additive. If two elements both specify a uniform margin of 10 pixels and are adjacent peers in any orientation, the distance between them is 20 pixels.
- Negative margins are permitted. However, using a negative margin can often cause clipping, or overdraws of peers, so it's not a common technique to use negative margins.
- Margin values are constrained last, so be careful with margins because containers can clip or constrain elements. A Margin value could be the cause of an element not appearing to render; with a Margin applied, an element's dimension can be constrained to 0.

Padding

Padding controls the amount of space between the inner border of an element and its child content or elements. A positive Padding value decreases the content area of the element.

Unlike Margin, Padding is not a property of FrameworkElement. There are several classes which each define their own Padding property:

- Control.Padding: inherits to all Control derived classes. Not all controls have content, so for those controls, setting the property does nothing. If the control has a border, the padding applies inside that border.
- Border.Padding: defines space between the rectangle line created by BorderThickness/BorderBrush and the Child element.
- ItemsPresenter.Padding: contributes to appearance of the items in item controls, placing the specified padding around each item.
- TextBlock.Padding and RichTextBlock.Padding: expand the bounding box around the text of the text element. These text elements don't have a **Background**, so it can be visually difficult to see. For that reason, use Margin settings on Block containers instead.

In each of these cases, elements also have a Margin property. If both Margin and Padding are applied, they are additive: the apparent distance between an outer container and any inner content will be margin plus padding.

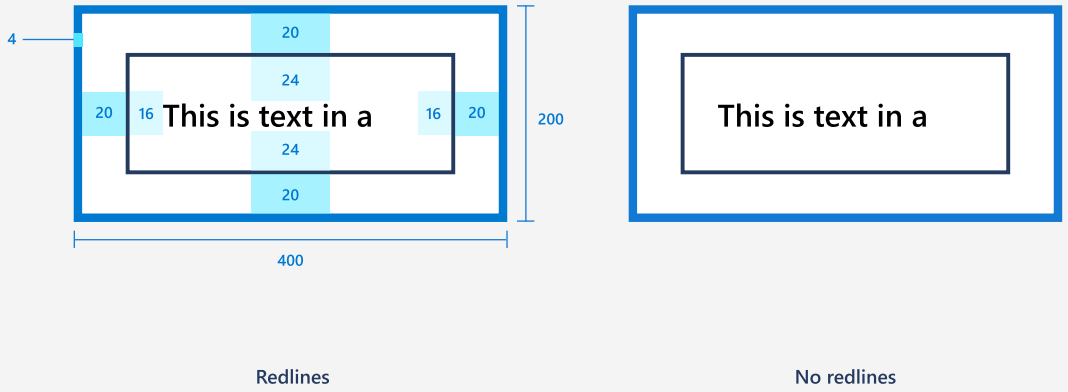
Example

Let's look at the effects of Margin and Padding on real controls. Here's a TextBox inside of a Grid with the default Margin and Padding values of 0.

Here's the same TextBox and Grid with Margin and Padding values on the TextBox as shown in this XAML.

XAML

```
<Grid BorderBrush="Blue" BorderThickness="4" Width="200">
    <TextBox Text="This is text in a TextBox." Margin="20" Padding="16,24"/>
</Grid>
```



Redlines

No redlines

Style resources

You don't have to set each property value individually on a control. It's typically more efficient to group property values into a **Style** resource and apply the Style to a control. This is especially true when you need to apply the same property values to many controls. For more info about using styles, see XAML styles.

General recommendations

- Only apply measurement values to certain key elements and use fluid layout behavior for the other elements. This provides for responsive UI when the window width changes.
- If you do use measurement values, **all dimensions, margins, and padding should be in increments of 4 epx**. When XAML uses effective pixels and scaling to make your app legible on all devices and screen sizes, it scales UI elements by multiples of 4. Using values in increments of 4 results in the best rendering by aligning with whole pixels.

- For small window widths (less than 640 pixels), we recommend 12 epx gutters, and for larger window widths, we recommend 24 epx gutters.

Responsive layouts with XAML

Article • 09/26/2024

The XAML layout system provides automatic sizing of elements, layout panels, and visual states to help you create a responsive UI. With a responsive layout, you can make your app look great on screens with different app window sizes, resolutions, pixel densities, and orientations. You can also use XAML to reposition, resize, reflow, show/hide, replace, or re-architect your app's UI, as discussed in Responsive design techniques. Here, we discuss how to implement responsive layouts with XAML.

Fluid layouts with properties and panels

The foundation of a responsive layout is the appropriate use of XAML layout properties and panels to reposition, resize, and reflow content in a fluid manner.

The XAML layout system supports both static and fluid layouts. In a static layout, you give controls explicit pixel sizes and positions. When the user changes the resolution or orientation of their device, the UI doesn't change. Static layouts can become clipped across different form factors and display sizes. On the other hand, fluid layouts shrink, grow, and reflow to respond to the visual space available on a device.

In practice, you use a combination of static and fluid elements to create your UI. You still use static elements and values in some places, but make sure that the overall UI is responsive to different resolutions, screen sizes, and views.

Here, we discuss how to use XAML properties and layout panels to create a fluid layout.

Layout properties

Layout properties control the size and position of an element. To create a fluid layout, use automatic or proportional sizing for elements, and allow layout panels to position their children as needed.

Here are some common layout properties and how to use them to create fluid layouts.

Height and Width

The **Height** and **Width** properties specify the size of an element. You can use fixed values measured in effective pixels, or you can use auto or proportional sizing.

Auto sizing resizes UI elements to fit their content or parent container. You can also use auto sizing with the rows and columns of a grid. To use auto sizing, set the Height

and/or Width of UI elements to **Auto**.

> **Note**
>
> Whether an element resizes to its content or its container depends on how the parent container handles sizing of its children. For more info, see Layout panels later in this article.

Proportional sizing, also called *star sizing*, distributes available space among the rows and columns of a grid by weighted proportions. In XAML, star values are expressed as * (or *n** for weighted star sizing). For example, to specify that one column is 5 times wider than the second column in a 2-column layout, use "5*" and "*" for the **Width** properties in the **ColumnDefinition** elements.

This example combines fixed, auto, and proportional sizing in a **Grid** with 4 columns.

Expand table

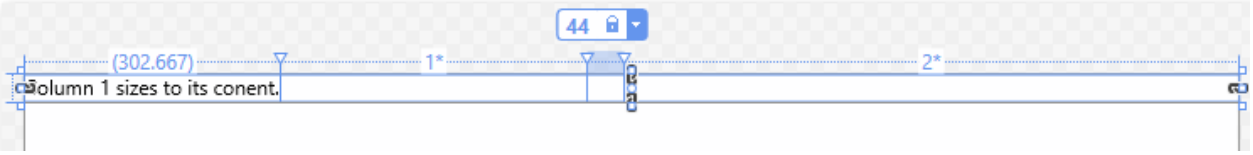
Column	Sizing	Description
Column_1	**Auto**	The column will size to fit its content.
Column_2	*	After the Auto columns are calculated, the column gets part of the remaining width. Column_2 will be one-half as wide as Column_4.
Column_3	**44**	The column will be 44 pixels wide.
Column_4	**2***	After the Auto columns are calculated, the column gets part of the remaining width. Column_4 will be twice as wide as Column_2.

The default column width is "*", so you don't need to explicitly set this value for the second column.

XAML

```
<Grid>
    <Grid.ColumnDefinitions>
        <ColumnDefinition Width="Auto"/>
        <ColumnDefinition/>
        <ColumnDefinition Width="44"/>
        <ColumnDefinition Width="2*"/>
    </Grid.ColumnDefinitions>
    <TextBlock Text="Column 1 sizes to its content." FontSize="24"/>
</Grid>
```

In the Visual Studio XAML designer, the result looks like this.



To get the size of an element at runtime, use the read-only **ActualHeight** and **ActualWidth** properties instead of Height and Width.

Size constraints

When you use auto sizing in your UI, you might still need to place constraints on the size of an element. You can set the **MinWidth**/**MaxWidth** and **MinHeight**/**MaxHeight** properties to specify values that constrain the size of an element while allowing fluid resizing.

In a Grid, MinWidth/MaxWidth can also be used with column definitions, and MinHeight/MaxHeight can be used with row definitions.

Alignment

Use the **HorizontalAlignment** and **VerticalAlignment** properties to specify how an element should be positioned within its parent container.

- The values for **HorizontalAlignment** are **Left**, **Center**, **Right**, and **Stretch**.
- The values for **VerticalAlignment** are **Top**, **Center**, **Bottom**, and **Stretch**.

With the **Stretch** alignment, elements fill all the space they're provided in the parent container. Stretch is the default for both alignment properties. However, some controls, like **Button**, override this value in their default style. Any element that can have child elements can treat the Stretch value for HorizontalAlignment and VerticalAlignment properties uniquely. For example, an element using the default Stretch values placed in a Grid stretches to fill the cell that contains it. The same element placed in a Canvas sizes to its content. For more info about how each panel handles the Stretch value, see the Layout panels article.

For more info, see the Alignment, margin, and padding article, and the **HorizontalAlignment** and **VerticalAlignment** reference pages.

Visibility

You can reveal or hide an element by setting its **Visibility** property to one of the **Visibility** enumeration values: **Visible** or **Collapsed**. When an element is Collapsed, it doesn't take up any space in the UI layout.

You can change an element's Visibility property in code or in a visual state. When the Visibility of an element is changed, all of its child elements are also changed. You can

replace sections of your UI by revealing one panel while collapsing another.

> **Tip**
>
> When you have elements in your UI that are **Collapsed** by default, the objects are still created at startup, even though they aren't visible. You can defer loading these elements until they are shown by using the **x:Load attribute** to delay the creation of the objects. This can improve startup performance. For more info, see **x:Load attribute**.

Style resources

You don't have to set each property value individually on a control. It's typically more efficient to group property values into a **Style** resource and apply the Style to a control. This is especially true when you need to apply the same property values to many controls. For more info about using styles, see Styling controls.

Layout panels

To position visual objects, you must put them in a panel or other container object. The XAML framework provides various panel classes, such as **Canvas**, **Grid**, **RelativePanel** and **StackPanel**, which serve as containers and enable you to position and arrange the UI elements within them.

The main thing to consider when choosing a layout panel is how the panel positions and sizes its child elements. You might also need to consider how overlapping child elements are layered on top of each other.

Here's a comparison of the main features of the panel controls provided in the XAML framework.

Expand table

Panel Control	Description
Canvas	**Canvas** doesn't support fluid UI; you control all aspects of positioning and sizing child elements. You typically use it for special cases like creating graphics or to define small static areas of a larger adaptive UI. You can use code or visual states to reposition elements at runtime. • Elements are positioned absolutely using Canvas.Top and Canvas.Left attached properties. • Layering can be explicitly specified using the Canvas.ZIndex attached property.

Panel Control	Description
	• Stretch values for HorizontalAlignment/VerticalAlignment are ignored. If an element's size is not set explicitly, it sizes to its content. • Child content is not visually clipped if larger than the panel. • Child content is not constrained by the bounds of the panel.
Grid	**Grid** supports fluid resizing of child elements. You can use code or visual states to reposition and reflow elements. • Elements are arranged in rows and columns using Grid.Row and Grid.Column attached properties. • Elements can span multiple rows and columns using Grid.RowSpan and Grid.ColumnSpan attached properties. • Stretch values for HorizontalAlignment/VerticalAlignment are respected. If an element's size is not set explicitly, it stretches to fill the available space in the grid cell. • Child content is visually clipped if larger than the panel. • Content size is constrained by the bounds of the panel, so scrollable content shows scroll bars if needed.
RelativePanel	• Elements are arranged in relation to the edge or center of the panel, and in relation to each other. • Elements are positioned using a variety of attached properties that control panel alignment, sibling alignment, and sibling position. • Stretch values for HorizontalAlignment/VerticalAlignment are ignored unless RelativePanel attached properties for alignment cause stretching (for example, an element is aligned to both the right and left edges of the panel). If an element's size is not set explicitly and it's not stretched, it sizes to its content. • Child content is visually clipped if larger than the panel. • Content size is constrained by the bounds of the panel, so scrollable content shows scroll bars if needed.
StackPanel	• Elements are stacked in a single line either vertically or horizontally. • Stretch values for HorizontalAlignment/VerticalAlignment are respected in the direction opposite the Orientation property. If an element's size is not set explicitly, it stretches to fill the available width (or height if the Orientation is Horizontal). In the direction specified by the Orientation property, an element sizes to its content. • Child content is visually clipped if larger than the panel. • Content size is not constrained by the bounds of the panel in the direction specified by the Orientation property, so scrollable content stretches beyond the panel bounds and doesn't show scrollbars. You must explicitly constrain the height (or width) of the child content to make its scrollbars show.
VariableSizedWrapGrid	• Elements are arranged in rows or columns that automatically wrap to a new row or column when the MaximumRowsOrColumns value is reached.

Panel Control	Description
	• Whether elements are arranged in rows or columns is specified by the Orientation property. • Elements can span multiple rows and columns using VariableSizedWrapGrid.RowSpan and VariableSizedWrapGrid.ColumnSpan attached properties. • Stretch values for HorizontalAlignment and VerticalAlignment are ignored. Elements are sized as specified by the ItemHeight and ItemWidth properties. If these properties are not set, they take their values from the size of the first cell. • Child content is visually clipped if larger than the panel. • Content size is constrained by the bounds of the panel, so scrollable content shows scroll bars if needed.

For detailed information and examples of these panels, see Layout panels.

Layout panels let you organize your UI into logical groups of controls. When you use them with appropriate property settings, you get some support for automatic resizing, repositioning, and reflowing of UI elements. However, most UI layouts need further modification when there are significant changes to the window size. For this, you can use visual states.

Adaptive layouts with visual states and state triggers

Use visual states to make significant alterations to your UI based on window size or other changes.

When your app window grows or shrinks beyond a certain amount, you might want to alter layout properties to reposition, resize, reflow, reveal, or replace sections of your UI. You can define different visual states for your UI, and apply them when the window width or window height crosses a specified threshold.

A **VisualState** defines property values that are applied to an element when it's in a particular state. You group visual states in a **VisualStateManager** that applies the appropriate VisualState when the specified conditions are met. An **AdaptiveTrigger** provides an easy way to set the threshold (also called 'breakpoint') where a state is applied in XAML. Or, you can call the **VisualStateManager.GoToState** method in your code to apply the visual state. Examples of both ways are shown in the next sections.

Set visual states in code

To apply a visual state from code, you call the VisualStateManager.GoToState method. For example, to apply a state when the app window is a particular size, handle the SizeChanged event and call **GoToState** to apply the appropriate state.

Here, a VisualStateGroup contains two VisualState definitions. The first, `DefaultState`, is empty. When it's applied, the values defined in the XAML page are applied. The second, `WideState`, changes the DisplayMode property of the SplitView to **Inline** and opens the pane. This state is applied in the SizeChanged event handler if the window width is greater than 640 effective pixels.

> **Note**
>
> Windows doesn't provide a way for your app to detect the specific device your app is running on. It can tell you the device family (desktop, etc) the app is running on, the effective resolution, and the amount of screen space available to the app (the size of the app's window). We recommend defining visual states for screen sizes and break points.

XAML

```
<Page ...
    SizeChanged="CurrentWindow_SizeChanged">
    <Grid>
        <VisualStateManager.VisualStateGroups>
            <VisualStateGroup>
                <VisualState x:Name="DefaultState">
                        <Storyboard>
                        </Storyboard>
                    </VisualState>

                <VisualState x:Name="WideState">
                    <Storyboard>
                        <ObjectAnimationUsingKeyFrames

Storyboard.TargetProperty="SplitView.DisplayMode"
                            Storyboard.TargetName="mySplitView">
                            <DiscreteObjectKeyFrame KeyTime="0">
                                <DiscreteObjectKeyFrame.Value>

<SplitViewDisplayMode>Inline</SplitViewDisplayMode>
                                </DiscreteObjectKeyFrame.Value>
                            </DiscreteObjectKeyFrame>
                        </ObjectAnimationUsingKeyFrames>
                        <ObjectAnimationUsingKeyFrames
                            Storyboard.TargetProperty="SplitView.IsPaneOpen"
                            Storyboard.TargetName="mySplitView">
                            <DiscreteObjectKeyFrame KeyTime="0"
Value="True"/>
```

```
                        </ObjectAnimationUsingKeyFrames>
                    </Storyboard>
                </VisualState>
            </VisualStateGroup>
        </VisualStateManager.VisualStateGroups>

        <SplitView x:Name="mySplitView" DisplayMode="CompactInline"
                   IsPaneOpen="False" CompactPaneLength="20">
            <!-- SplitView content -->

            <SplitView.Pane>
                <!-- Pane content -->
            </SplitView.Pane>
        </SplitView>
    </Grid>
</Page>
```

C#

```
private void CurrentWindow_SizeChanged(object sender,
Windows.UI.Core.WindowSizeChangedEventArgs e)
{
    if (e.Size.Width > 640)
        VisualStateManager.GoToState(this, "WideState", false);
    else
        VisualStateManager.GoToState(this, "DefaultState", false);
}
```

Set visual states in XAML markup

Prior to Windows 10, VisualState definitions required **Storyboard** objects for property changes, and you had to call **GoToState** in code to apply the state. This is shown in the previous example. You will still see many examples that use this syntax, or you might have existing code that uses it.

Starting in Windows 10, you can use the simplified **Setter** syntax shown here, and you can use a **StateTrigger** in your XAML markup to apply the state. You use state triggers to create simple rules that automatically trigger visual state changes in response to an app event.

This example does the same thing as the previous example, but uses the simplified **Setter** syntax instead of a Storyboard to define property changes. And instead of calling GoToState, it uses the built in **AdaptiveTrigger** state trigger to apply the state. When you use state triggers, you don't need to define an empty `DefaultState`. The default settings are reapplied automatically when the conditions of the state trigger are no longer met.

XAML

```
<Page ...>
    <Grid>
        <VisualStateManager.VisualStateGroups>
            <VisualStateGroup>
                <VisualState>
                    <VisualState.StateTriggers>
                        <!-- VisualState to be triggered when the
                             window width is >=640 effective pixels. -->
                        <AdaptiveTrigger MinWindowWidth="640" />
                    </VisualState.StateTriggers>

                    <VisualState.Setters>
                        <Setter Target="mySplitView.DisplayMode"
Value="Inline"/>
                        <Setter Target="mySplitView.IsPaneOpen"
Value="True"/>
                    </VisualState.Setters>
                </VisualState>
            </VisualStateGroup>
        </VisualStateManager.VisualStateGroups>

        <SplitView x:Name="mySplitView" DisplayMode="CompactInline"
                   IsPaneOpen="False" CompactPaneLength="20">
            <!-- SplitView content -->

            <SplitView.Pane>
                <!-- Pane content -->
            </SplitView.Pane>
        </SplitView>
    </Grid>
</Page>
```

ⓘ Important

In the previous example, the VisualStateManager.VisualStateGroups attached property is set on the **Grid** element. When you use StateTriggers, always ensure that VisualStateGroups is attached to the first child of the root in order for the triggers to take effect automatically. (Here, **Grid** is the first child of the root **Page** element.)

Attached property syntax

In a VisualState, you typically set a value for a control property, or for one of the attached properties of the panel that contains the control. When you set an attached property, use parentheses around the attached property name.

This example shows how to set the RelativePanel.AlignHorizontalCenterWithPanel attached property on a TextBox named `myTextBox`. The first XAML uses ObjectAnimationUsingKeyFrames syntax and the second uses **Setter** syntax.

XAML

```
<!-- Set an attached property using ObjectAnimationUsingKeyFrames. -->
<ObjectAnimationUsingKeyFrames
    Storyboard.TargetProperty="
(RelativePanel.AlignHorizontalCenterWithPanel)"
    Storyboard.TargetName="myTextBox">
    <DiscreteObjectKeyFrame KeyTime="0" Value="True"/>
</ObjectAnimationUsingKeyFrames>

<!-- Set an attached property using Setter. -->
<Setter Target="myTextBox.(RelativePanel.AlignHorizontalCenterWithPanel)"
Value="True"/>
```

Custom state triggers

You can extend the **StateTrigger** class to create custom triggers for a wide range of scenarios. For example, you can create a StateTrigger to trigger different states based on input type, then increase the margins around a control when the input type is touch. Or create a StateTrigger to apply different states based on the device family the app is run on. For examples of how to build custom triggers and use them to create optimized UI experiences from within a single XAML view, see the State triggers sample.

Visual states and styles

You can use Style resources in visual states to apply a set of property changes to multiple controls. For more info about using styles, see Styling controls.

In this simplified XAML from the State triggers sample, a Style resource is applied to a Button to adjust the size and margins for mouse or touch input. For the complete code and the definition of the custom state trigger, see the State triggers sample.

XAML

```
<Page ... >
    <Page.Resources>
        <!-- Styles to be used for mouse vs. touch/pen hit targets -->
        <Style x:Key="MouseStyle" TargetType="Rectangle">
            <Setter Property="Margin" Value="5" />
            <Setter Property="Height" Value="20" />
            <Setter Property="Width" Value="20" />
        </Style>
```

```
        <Style x:Key="TouchPenStyle" TargetType="Rectangle">
            <Setter Property="Margin" Value="15" />
            <Setter Property="Height" Value="40" />
            <Setter Property="Width" Value="40" />
        </Style>
    </Page.Resources>

    <RelativePanel>
        <!-- ... -->
        <Button Content="Color Palette Button" x:Name="MenuButton">
            <Button.Flyout>
                <Flyout Placement="Bottom">
                    <RelativePanel>
                        <Rectangle Name="BlueRect" Fill="Blue"/>
                        <Rectangle Name="GreenRect" Fill="Green"
RelativePanel.RightOf="BlueRect" />
                        <!-- ... -->
                    </RelativePanel>
                </Flyout>
            </Button.Flyout>
        </Button>
        <!-- ... -->
    </RelativePanel>
    <VisualStateManager.VisualStateGroups>
        <VisualStateGroup x:Name="InputTypeStates">
            <!-- Second set of VisualStates for building responsive UI
optimized for input type.
                 Take a look at InputTypeTrigger.cs class in CustomTriggers
folder to see how this is implemented. -->
            <VisualState>
                <VisualState.StateTriggers>
                    <!-- This trigger indicates that this VisualState is to
be applied when MenuButton is invoked using a mouse. -->
                    <triggers:InputTypeTrigger TargetElement="{x:Bind
MenuButton}" PointerType="Mouse" />
                </VisualState.StateTriggers>
                <VisualState.Setters>
                    <Setter Target="BlueRect.Style" Value="{StaticResource
MouseStyle}" />
                    <Setter Target="GreenRect.Style" Value="{StaticResource
MouseStyle}" />
                    <!-- ... -->
                </VisualState.Setters>
            </VisualState>
            <VisualState>
                <VisualState.StateTriggers>
                    <!-- Multiple trigger statements can be declared in the
following way to imply OR usage.
                         For example, the following statements indicate that
this VisualState is to be applied when MenuButton is invoked using Touch OR
Pen.-->
                    <triggers:InputTypeTrigger TargetElement="{x:Bind
MenuButton}" PointerType="Touch" />
                    <triggers:InputTypeTrigger TargetElement="{x:Bind
MenuButton}" PointerType="Pen" />
```

```
                </VisualState.StateTriggers>
                <VisualState.Setters>
                    <Setter Target="BlueRect.Style" Value="{StaticResource
TouchPenStyle}" />
                    <Setter Target="GreenRect.Style" Value="{StaticResource
TouchPenStyle}" />
                    <!-- ... -->
                </VisualState.Setters>
            </VisualState>
        </VisualStateGroup>
    </VisualStateManager.VisualStateGroups>
</Page>
```

Layout panels

Article • 05/24/2022

Layout panels are containers that allow you to arrange and group UI elements in your app. The built-in XAML layout panels include **RelativePanel**, **StackPanel**, **Grid**, **VariableSizedWrapGrid**, and **Canvas**. Here, we describe each panel and show how to use it to layout XAML UI elements.

There are several things to consider when choosing a layout panel:

- How the panel positions its child elements.
- How the panel sizes its child elements.
- How overlapping child elements are layered on top of each other (z-order).
- The number and complexity of nested panel elements needed to create your desired layout.

Examples

Expand table

WinUI 2 Gallery
 If you have the **WinUI 2 Gallery** app installed, see the RelativePanel, StackPanel, Grid, VariableSizedWrapGrid, and Canvas in action. • Get the WinUI 2 Gallery app (Microsoft Store) • Get the source code (GitHub)

Panel properties

Before we discuss individual panels, let's go over some common properties that all panels have.

Panel attached properties

Most XAML layout panels use attached properties to let their child elements inform the parent panel about how they should be positioned in the UI. Attached properties use the syntax *AttachedPropertyProvider.PropertyName*. If you have panels that are nested inside other panels, attached properties on UI elements that specify layout characteristics to a parent are interpreted by the most immediate parent panel only.

Here is an example of how you can set the **Canvas.Left** attached property on a Button control in XAML. This informs the parent Canvas that the Button should be positioned 50 effective pixels from the left edge of the Canvas.

XAML

```
<Canvas>
  <Button Canvas.Left="50">Hello</Button>
</Canvas>
```

For more info about attached properties, see Attached properties overview.

Panel borders

The RelativePanel, StackPanel, and Grid panels define border properties that let you draw a border around the panel without wrapping them in an additional Border element. The border properties are **BorderBrush**, **BorderThickness**, **CornerRadius**, and **Padding**.

Here's an example of how to set border properties on a Grid.

XAML

```
<Grid BorderBrush="Blue" BorderThickness="12" CornerRadius="12"
Padding="12">
    <TextBlock Text="Hello World!"/>
</Grid>
```

Using the built-in border properties reduces the XAML element count, which can improve the UI performance of your app. For more info about layout panels and UI performance, see Optimize your XAML layout.

RelativePanel

RelativePanel lets you layout UI elements by specifying where they go in relation to other elements and in relation to the panel. By default, an element is positioned in the upper left corner of the panel. You can use RelativePanel with VisualStateManager and AdaptiveTrigger to rearrange your UI for different window sizes.

This table shows the attached properties you can use to align an element in relation to the panel or other elements.

Expand table

Panel alignment	Sibling alignment	Sibling position
AlignTopWithPanel	AlignTopWith	Above
AlignBottomWithPanel	AlignBottomWith	Below
AlignLeftWithPanel	AlignLeftWith	LeftOf
AlignRightWithPanel	AlignRightWith	RightOf
AlignHorizontalCenterWithPanel	AlignHorizontalCenterWith	
AlignVerticalCenterWithPanel	AlignVerticalCenterWith	

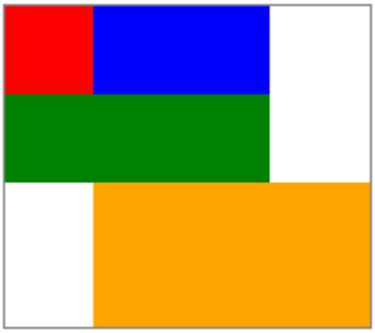
This XAML shows how to arrange elements in a RelativePanel.

XAML

```
<RelativePanel BorderBrush="Gray" BorderThickness="1">
    <Rectangle x:Name="RedRect" Fill="Red" Height="44" Width="44"/>
    <Rectangle x:Name="BlueRect" Fill="Blue"
               Height="44" Width="88"
               RelativePanel.RightOf="RedRect" />

    <Rectangle x:Name="GreenRect" Fill="Green"
               Height="44"
               RelativePanel.Below="RedRect"
               RelativePanel.AlignLeftWith="RedRect"
               RelativePanel.AlignRightWith="BlueRect"/>
    <Rectangle Fill="Orange"
               RelativePanel.Below="GreenRect"
               RelativePanel.AlignLeftWith="BlueRect"
               RelativePanel.AlignRightWithPanel="True"
               RelativePanel.AlignBottomWithPanel="True"/>
</RelativePanel>
```

The result looks like this.



Here are a few things to note about the sizing of the rectangles:

- The red rectangle is given an explicit size of 44x44. It's placed in the upper left corner of the panel, which is the default position.
- The green rectangle is given an explicit height of 44. Its left side is aligned with the red rectangle, and its right side is aligned with the blue rectangle, which determines its width.
- The orange rectangle isn't given an explicit size. Its left side is aligned with the blue rectangle. Its right and bottom edges are aligned with the edge of the panel. Its size is determined by these alignments and it will resize as the panel resizes.

StackPanel

StackPanel arranges its child elements into a single line that can be oriented horizontally or vertically. StackPanel is typically used to arrange a small subsection of the UI on a page.

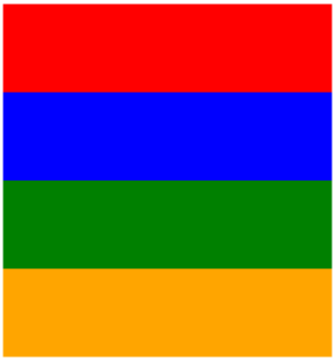
You can use the **Orientation** property to specify the direction of the child elements. The default orientation is **Vertical**.

The following XAML shows how to create a vertical StackPanel of items.

XAML

```
<StackPanel>
    <Rectangle Fill="Red" Height="44"/>
    <Rectangle Fill="Blue" Height="44"/>
    <Rectangle Fill="Green" Height="44"/>
    <Rectangle Fill="Orange" Height="44"/>
</StackPanel>
```

The result looks like this.



In a StackPanel, if a child element's size is not set explicitly, it stretches to fill the available width (or height if the Orientation is **Horizontal**). In this example, the width of the rectangles is not set. The rectangles expand to fill the entire width of the StackPanel.

Grid

The **Grid** panel supports fluid layouts and allows you to arrange controls in multi-row and multi-column layouts. You specify a Grid's rows and columns by using the **RowDefinitions** and **ColumnDefinitions** properties.

To position objects in specific cells of the Grid, use the **Grid.Column** and **Grid.Row** attached properties.

To make content span across multiple rows and columns, use the **Grid.RowSpan** and **Grid.ColumnSpan** attached properties.

This XAML example shows how to create a Grid with two rows and two columns.

XAML

```
<Grid>
    <Grid.RowDefinitions>
        <RowDefinition/>
        <RowDefinition Height="44"/>
    </Grid.RowDefinitions>
    <Grid.ColumnDefinitions>
        <ColumnDefinition Width="Auto"/>
        <ColumnDefinition/>
    </Grid.ColumnDefinitions>
    <Rectangle Fill="Red" Width="44"/>
    <Rectangle Fill="Blue" Grid.Row="1"/>
    <Rectangle Fill="Green" Grid.Column="1"/>
    <Rectangle Fill="Orange" Grid.Row="1" Grid.Column="1"/>
</Grid>
```

The result looks like this.

In this example, the sizing works like this:

- The second row has an explicit height of 44 effective pixels. By default, the height of the first row fills whatever space is left over.
- The width of the first column is set to **Auto**, so it's as wide as needed for its children. In this case, it's 44 effective pixels wide to accommodate the width of the red rectangle.
- There are no other size constraints on the rectangles, so each one stretches to fill the grid cell it's in.

You can distribute space within a column or a row by using **Auto** or star sizing. You use auto sizing to let UI elements resize to fit their content or parent container. You can also use auto sizing with the rows and columns of a grid. To use auto sizing, set the Height and/or Width of UI elements to **Auto**.

You use proportional sizing, also called *star sizing*, to distribute available space among the rows and columns of a grid by weighted proportions. In XAML, star values are expressed as * (or *n** for weighted star sizing). For example, to specify that one column is 5 times wider than the second column in a 2-column layout, use "5*" and "*" for the **Width** properties in the **ColumnDefinition** elements.

This example combines fixed, auto, and proportional sizing in a **Grid** with 4 columns.

Expand table

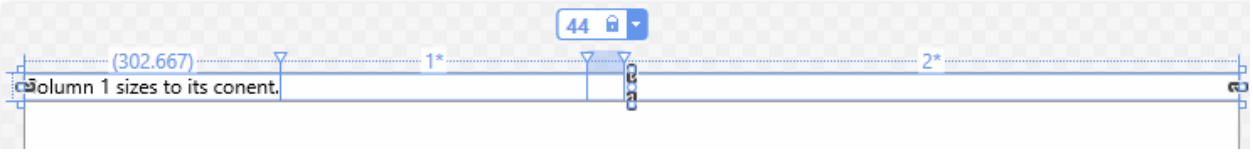
Column	Sizing	Description
Column_1	**Auto**	The column will size to fit its content.
Column_2	*	After the Auto columns are calculated, the column gets part of the remaining width. Column_2 will be one-half as wide as Column_4.
Column_3	**44**	The column will be 44 pixels wide.
Column_4	**2***	After the Auto columns are calculated, the column gets part of the remaining width. Column_4 will be twice as wide as Column_2.

The default column width is "*", so you don't need to explicitly set this value for the second column.

XAML

```
<Grid>
    <Grid.ColumnDefinitions>
        <ColumnDefinition Width="Auto"/>
        <ColumnDefinition/>
        <ColumnDefinition Width="44"/>
        <ColumnDefinition Width="2*"/>
    </Grid.ColumnDefinitions>
    <TextBlock Text="Column 1 sizes to its content." FontSize="24"/>
</Grid>
```

In the Visual Studio XAML designer, the result looks like this.



VariableSizedWrapGrid

VariableSizedWrapGrid is a Grid-style layout panel where rows or columns automatically wrap to a new row or column when the MaximumRowsOrColumns value is reached.

The Orientation property specifies whether the grid adds its items in rows or columns before wrapping. The default orientation is **Vertical**, which means the grid adds items from top to bottom until a column is full, then wraps to a new column. When the value is **Horizontal**, the grid adds items from left to right, then wraps to a new row.

Cell dimensions are specified by the ItemHeight and ItemWidth. Each cell is the same size. If ItemHeight or ItemWidth is not specified, then the first cell sizes to fit its content, and every other cell is the size of the first cell.

You can use the VariableSizedWrapGrid.ColumnSpan and VariableSizedWrapGrid.RowSpan attached properties to specify how many adjacent cells a child element should fill.

Here's how to use a VariableSizedWrapGrid in XAML.

XAML

```
<VariableSizedWrapGrid MaximumRowsOrColumns="3" ItemHeight="44"
ItemWidth="44">
    <Rectangle Fill="Red"/>
    <Rectangle Fill="Blue"
               VariableSizedWrapGrid.RowSpan="2"/>
    <Rectangle Fill="Green"
               VariableSizedWrapGrid.ColumnSpan="2"/>
    <Rectangle Fill="Orange"
               VariableSizedWrapGrid.RowSpan="2"
               VariableSizedWrapGrid.ColumnSpan="2"/>
</VariableSizedWrapGrid>
```

The result looks like this.

In this example, the maximum number of rows in each column is 3. The first column contains only 2 items (the red and blue rectangles) because the blue rectangle spans 2 rows. The green rectangle then wraps to the top of the next column.

Canvas

The **Canvas** panel positions its child elements using fixed coordinate points and does not support fluid layouts. You specify the points on individual child elements by setting the **Canvas.Left** and **Canvas.Top** attached properties on each element. The parent Canvas reads these attached property values from its children during the Arrange pass of layout.

Objects in a Canvas can overlap, where one object is drawn on top of another object. By default, the Canvas renders child objects in the order in which they're declared, so the last child is rendered on top (each element has a default z-index of 0). This is the same as other built-in panels. However, Canvas also supports the **Canvas.ZIndex** attached property that you can set on each of the child elements. You can set this property in code to change the draw order of elements during run time. The element with the highest Canvas.ZIndex value draws last and therefore draws over any other elements that share the same space or overlap in any way. Note that alpha value (transparency) is respected, so even if elements overlap, the contents shown in overlap areas might be blended if the top one has a non-maximum alpha value.

The Canvas does not do any sizing of its children. Each element must specify its size.

Here's an example of a Canvas in XAML.

XAML

```
<Canvas Width="120" Height="120">
    <Rectangle Fill="Red" Height="44" Width="44"/>
    <Rectangle Fill="Blue" Height="44" Width="44" Canvas.Left="20"
Canvas.Top="20"/>
    <Rectangle Fill="Green" Height="44" Width="44" Canvas.Left="40"
Canvas.Top="40"/>
    <Rectangle Fill="Orange" Height="44" Width="44" Canvas.Left="60"
Canvas.Top="60"/>
</Canvas>
```

The result looks like this.

Use the Canvas panel with discretion. While it's convenient to be able to precisely control positions of elements in UI for some scenarios, a fixed positioned layout panel causes that area of your UI to be less adaptive to overall app window size changes. App window resize might come from device orientation changes, split app windows, changing monitors, and a number of other user scenarios.

Panels for ItemsControl

There are several special-purpose panels that can be used only as an **ItemsPanel** to display items in an **ItemsControl**. These are **ItemsStackPanel**, **ItemsWrapGrid**, **VirtualizingStackPanel**, and **WrapGrid**. You can't use these panels for general UI layout.

Materials in Windows

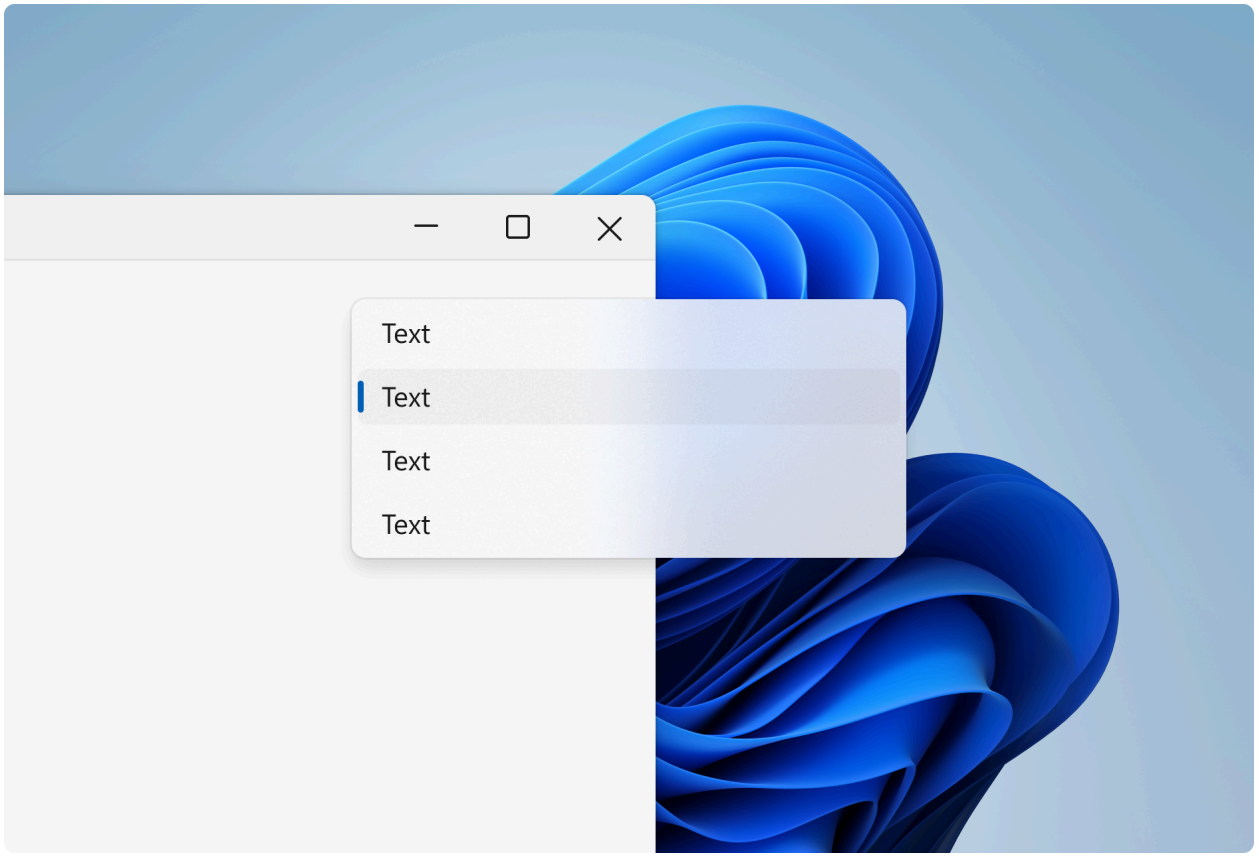
Article • 11/05/2024

Materials are visual effects applied to UX surfaces that resemble real life artifacts. Windows uses two primary types of materials: occluding and transparent. Occluding materials, like *acrylic* and *mica*, are used as base layers beneath interactive UI controls. Transparent materials such as *smoke* are used to highlight immersive surfaces.

Mica, Acrylic, and Smoke each have a specific purpose in how they are used throughout Windows.

> **Tip**
>
> This article describes how the Fluent Design language is applied to Windows apps. For more information, see Fluent Design - Material.

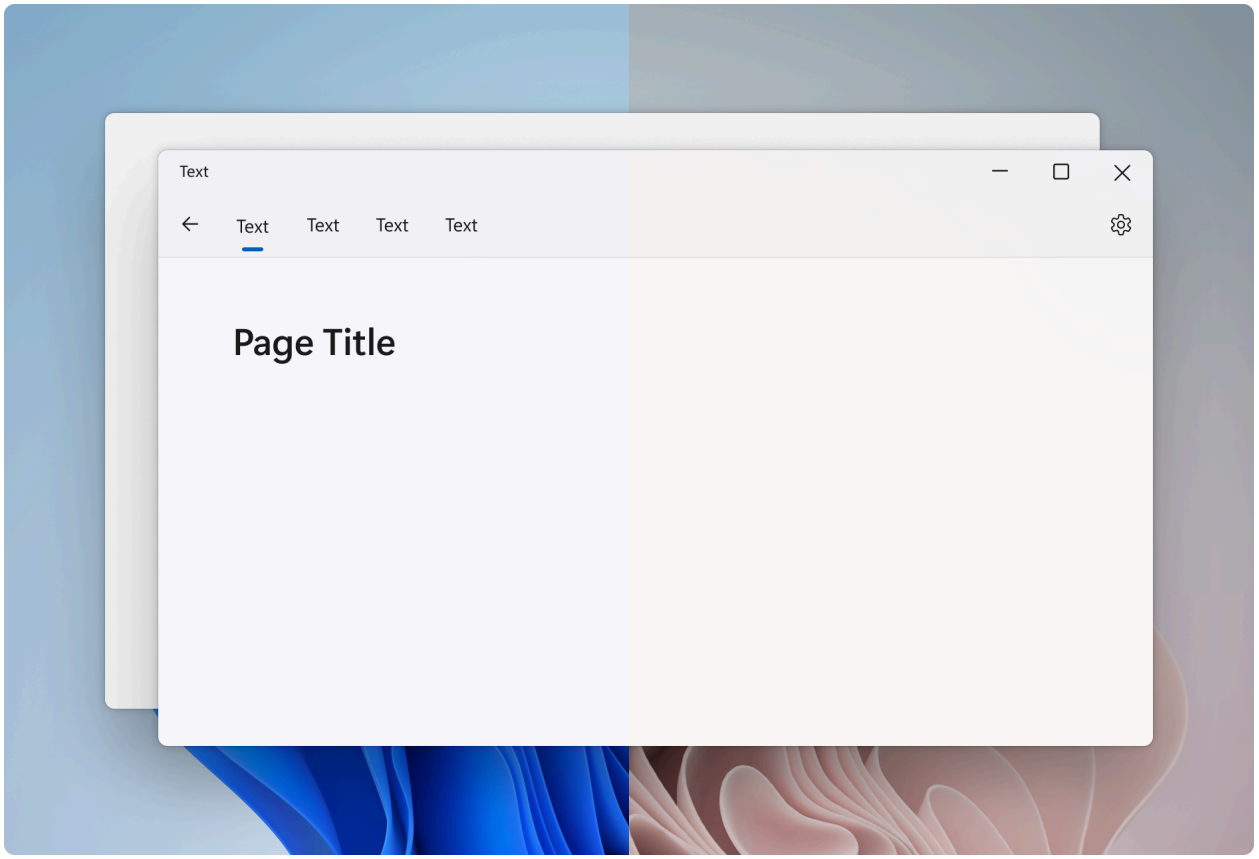
Acrylic



Acrylic is a semi-transparent material that replicates the effect of frosted glass. In Windows 11, acrylic has been updated to be brighter and more translucent, allowing for a stronger contextual relationship with the visuals behind it. Acrylic is used only for transient, light-dismiss surfaces such as flyouts and context menus.

Acrylic is mode aware; it supports both light and dark mode.

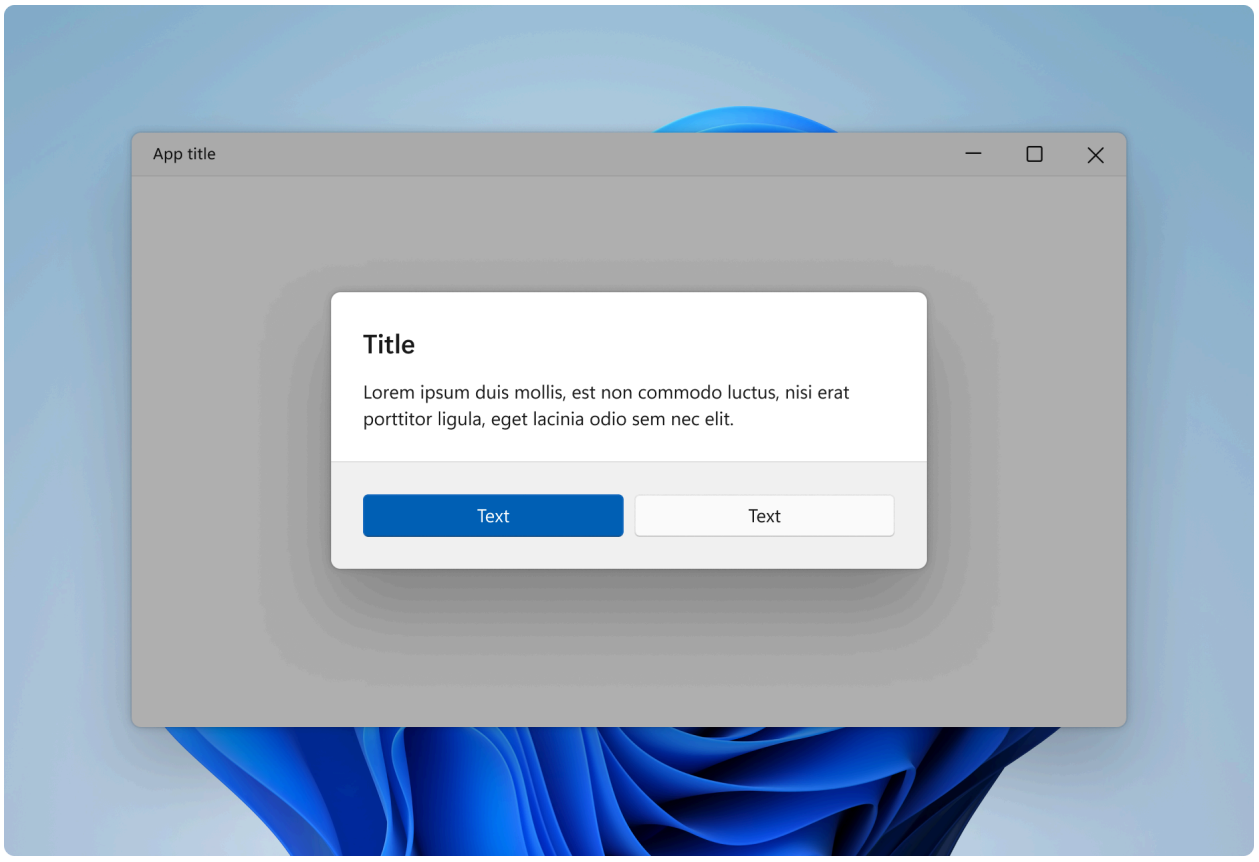
Mica



Mica is a new opaque material introduced in Windows 11. Mica surfaces are subtly tinted with the user's desktop background color.

Mica is mode aware; it supports both light and dark modes. Mica also indicates window focus with active and inactive states as a built in feature.

Smoke



Smoke emphasizes an important UI surface by dimming the surfaces beneath so that they recede into the background. Smoke is used to signal blocking interaction below a modal UI such as a dialog.

Smoke is not mode aware; it is always translucent black in both light and dark mode.

Acrylic material

Article • 07/16/2024

Acrylic is a type of Brush that creates a translucent texture. You can apply acrylic to app surfaces to add depth and help establish a visual hierarchy.

> **Important APIs**: AcrylicBrush class, Background property, Window.SystemBackdrop property, DesktopAcrylicBackdrop class

Acrylic in light theme

Acrylic in dark theme

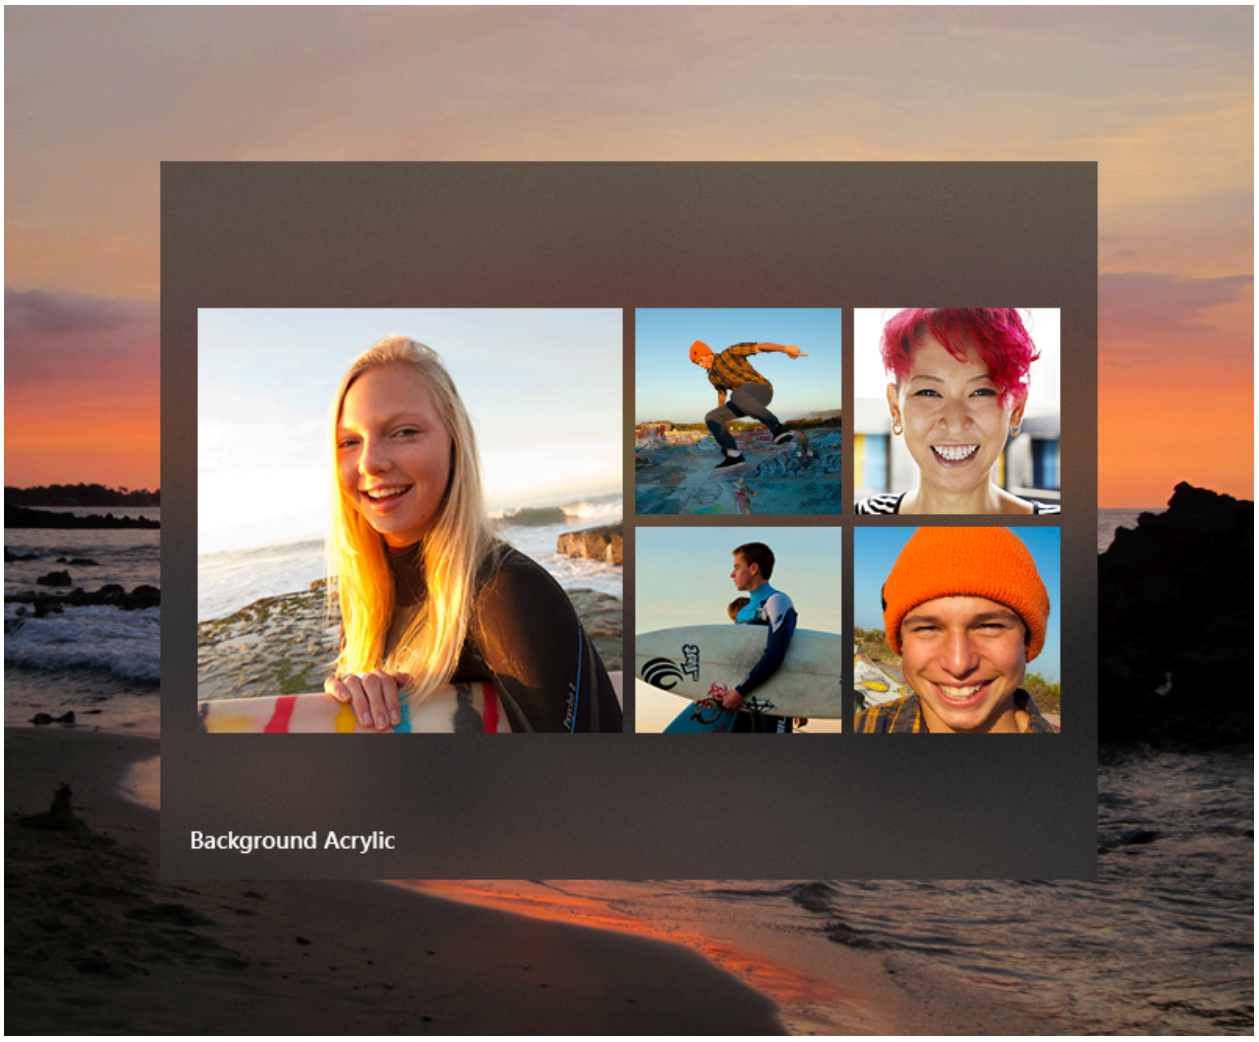
Acrylic and the Fluent Design System

The Fluent Design System helps you create modern, bold UI that incorporates light, depth, motion, material, and scale. Acrylic is a Fluent Design System component that adds physical texture (material) and depth to your app. To learn more, see Fluent Design - Material.

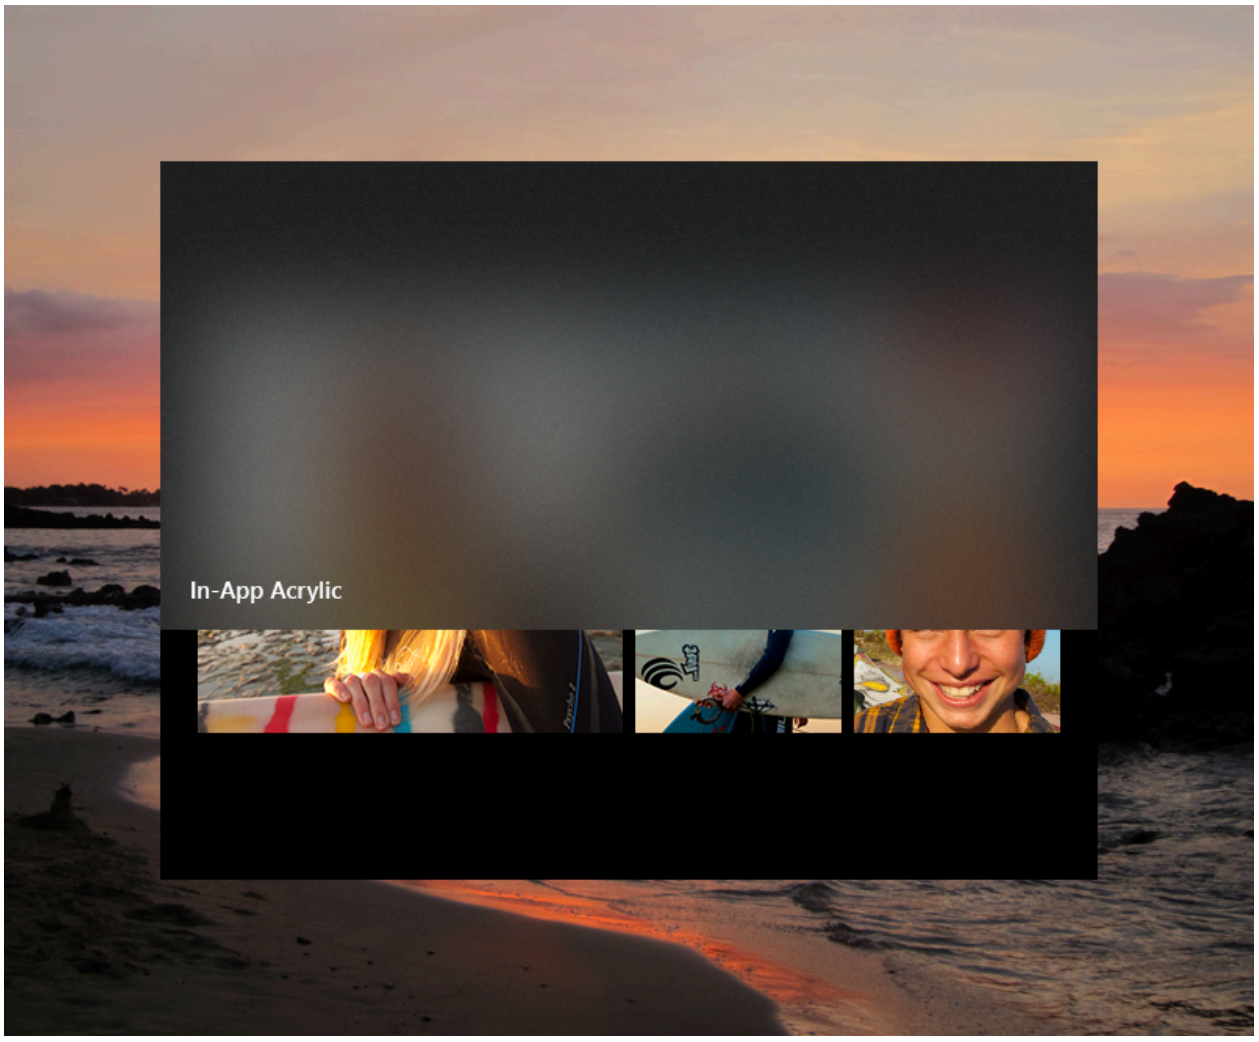
Acrylic blend types

Acrylic's most noticeable characteristic is its transparency. There are two acrylic blend types that change what's visible through the material:

- **Background acrylic** reveals the desktop wallpaper and other windows that are behind the currently active app, adding depth between application windows while celebrating the user's personalization preferences.
- **In-app acrylic** adds a sense of depth within the app frame, providing both focus and hierarchy.



Background Acrylic



Avoid layering multiple acrylic surfaces: multiple layers of background acrylic can create distracting optical illusions.

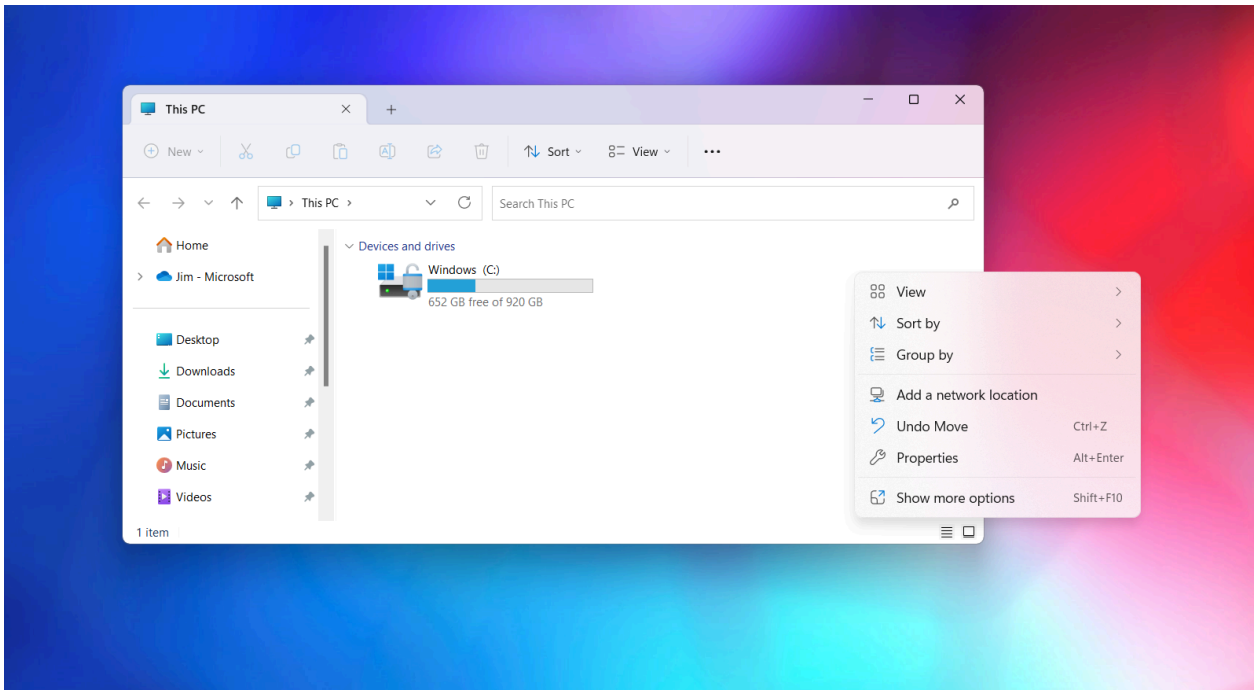
When to use acrylic

Consider the following usage patterns to decide how best to incorporate acrylic into your app.

Transient surfaces

- Use **background acrylic** for transient UI elements.

For apps with context menus, flyouts, non-modal popups, or light-dismiss panes, we recommend that you use background acrylic, especially if these surfaces draw outside the frame of the main app window. Using acrylic in transient scenarios helps maintain a visual relationship with the content that triggered the transient UI.



Many XAML controls draw acrylic by default. MenuFlyout, AutoSuggestBox, ComboBox, and similar controls with light-dismiss popups all use acrylic while open.

Supporting UI and vertical panes

- Use **in-app acrylic** for supporting UI, such as on surfaces that may overlap content when scrolled or interacted with.

If you are using in-app acrylic on navigation surfaces, consider extending content beneath the acrylic pane to improve the flow in your app. Using NavigationView will do this for you automatically. However, to avoid creating a striping effect, try not to place multiple pieces of acrylic edge-to-edge - this can create an unwanted seam between the two blurred surfaces. Acrylic is a tool to bring visual harmony to your designs, but when used incorrectly can result in visual noise.

For vertical panes or surfaces that help section off content of your app, we recommend you use an opaque background instead of acrylic. If your vertical panes open on top of content, like in NavigationView's **Compact** or **Minimal** modes, we suggest you use in-app acrylic to help maintain the page's context when the user has this pane open.

> **Note**
>
> Rendering acrylic surfaces is GPU-intensive, which can increase device power consumption and shorten battery life. Acrylic effects are automatically disabled when a device enters Battery Saver mode. Users can disable acrylic effects for all apps by turning off *Transparency effects* in Settings > Personalization > Colors.

Usability and adaptability

Acrylic automatically adapts its appearance for a wide variety of devices and contexts.

In High Contrast mode, users continue to see the familiar background color of their choosing in place of acrylic. In addition, both background acrylic and in-app acrylic appear as a solid color:

- When the user turns off *Transparency effects* in Settings > Personalization > Colors.
- When Battery Saver mode is activated.
- When the app runs on low-end hardware.

In addition, only background acrylic will replace its translucency and texture with a solid color:

- When an app window on desktop deactivates.
- When the app is running on Xbox, HoloLens, or in tablet mode.

Legibility considerations

It's important to ensure that any text your app presents to users meets contrast ratios (see Accessible text requirements). We've optimized the acrylic resources such that text meets contrast ratios on top of acrylic. We don't recommend placing accent-colored text on your acrylic surfaces because these combinations are likely to not pass minimum contrast ratio requirements at the default 14px font size. Try to avoid placing hyperlinks over acrylic elements. Also, if you choose to customize the acrylic tint color or opacity level, keep the impact on legibility in mind.

Apply acrylic in your app

> **ⓘ Important**
>
> How you apply background acrylic differs between WinUI 3 and WinUI 2/UWP.
>
> **WinUI 2/UWP**: The AcrylicBrush class has a BackgroundSource property that specifies whether you want background or in-app acrylic. You use an AcrylicBrush to apply both types of acrylic. See the AcrylicBrush classes for specific information and examples: Microsoft.UI.Xaml.Media.AcrylicBrush (WinUI 2), Windows.UI.Xaml.Media.AcrylicBrush (UWP).

WinUI 3: The AcrylicBrush class only supports in-app acrylic. You use the DesktopAcrylicBackdrop class to apply background acrylic.

Background acrylic

To apply background acrylic in a WinUI 3 app, set the element's `SystemBackdrop` property to an instance of DesktopAcrylicBackdrop. For more info, see Apply Mica or Acrylic materials in desktop apps for Windows 11.

These elements have a `SystemBackdrop` property:

- CommandBarFlyoutCommandBar.SystemBackdrop
- ContentIsland.SystemBackdrop
- DesktopWindowXamlSource.SystemBackdrop
- FlyoutBase.SystemBackdrop
- MenuFlyoutPresenter.SystemBackdrop
- Popup.SystemBackdrop
- Window.SystemBackdrop

In-app acrylic

You can apply in-app acrylic to your app's surfaces using a XAML AcrylicBrush or predefined `AcrylicBrush` theme resources.

WinUI includes a collection of brush theme resources that respect the app's theme and fall back to solid colors as needed. To paint a specific surface, apply one of the theme resources to element backgrounds just as you would apply any other brush resource.

XAML

```
<Grid Background="{ThemeResource AcrylicInAppFillColorDefaultBrush}">
```

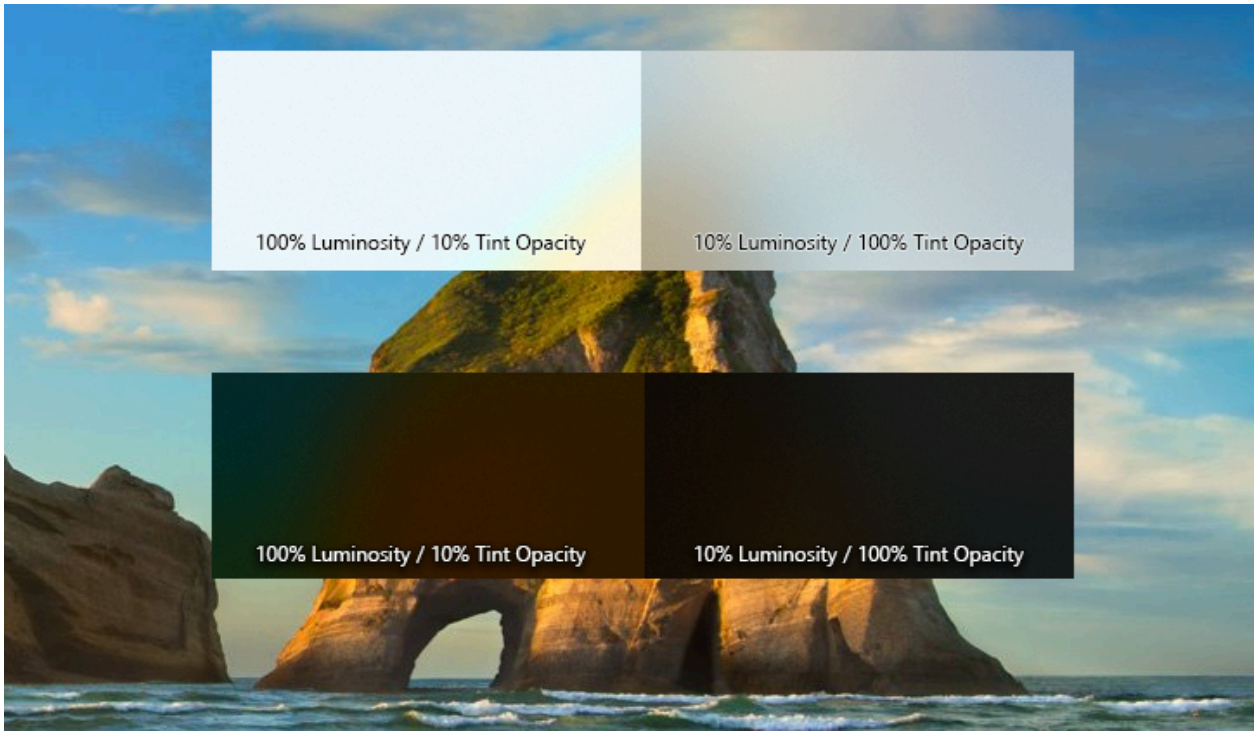
> **Note**
>
> You can view these resources in the AcrylicBrush theme resources file, in the microsoft-ui-xaml GitHub repo.
>
> For WinUI 2, resources that include *Background* in their names represent background acrylic, while *InApp* refers to in-app acrylic.

WinUI 3 includes the *Background* resources for compatibility, but they behave the same as *InApp* resources.

Custom acrylic brush

You may choose to add a color tint to your app's acrylic to show branding or provide visual balance with other elements on the page. To show color rather than grayscale, you'll need to define your own acrylic brushes using the following properties.

- **TintColor**: the color/tint overlay layer.
- **TintOpacity**: the opacity of the tint layer.
- **TintLuminosityOpacity**: controls the amount of saturation that is allowed through the acrylic surface from the background.
- **BackgroundSource**: (WinUI 2/UWP only) the flag to specify whether you want background or in-app acrylic.
- **FallbackColor**: the solid color that replaces acrylic in Battery Saver. For background acrylic, fallback color also replaces acrylic when your app isn't in the active desktop window.



To add an acrylic brush, define the three resources for dark, light, and high contrast themes. In high contrast, we recommend that you use a SolidColorBrush with the same `x:Key` as the dark/light AcrylicBrush.

> ⓘ **Note**

If you don't specify a `TintLuminosityOpacity` value, the system will automatically adjust its value based on your TintColor and TintOpacity.

XAML

```
<ResourceDictionary.ThemeDictionaries>
    <ResourceDictionary x:Key="Default">
        <AcrylicBrush x:Key="MyAcrylicBrush"
            BackgroundSource="HostBackdrop"
            TintColor="#FFFF0000"
            TintOpacity="0.8"
            TintLuminosityOpacity="0.5"
            FallbackColor="#FF7F0000"/>
    </ResourceDictionary>

    <ResourceDictionary x:Key="HighContrast">
        <SolidColorBrush x:Key="MyAcrylicBrush"
            Color="{ThemeResource SystemColorWindowColor}"/>
    </ResourceDictionary>

    <ResourceDictionary x:Key="Light">
        <AcrylicBrush x:Key="MyAcrylicBrush"
            BackgroundSource="HostBackdrop"
            TintColor="#FFFF0000"
            TintOpacity="0.8"
            TintLuminosityOpacity="0.5"
            FallbackColor="#FFFF7F7F"/>
    </ResourceDictionary>
</ResourceDictionary.ThemeDictionaries>
```

The following sample shows how to declare an AcrylicBrush in code.

C#

```
AcrylicBrush myBrush = new AcrylicBrush();
myBrush.TintColor = Color.FromArgb(255, 202, 24, 37);
myBrush.FallbackColor = Color.FromArgb(255, 202, 24, 37);
myBrush.TintOpacity = 0.6;

grid.Fill = myBrush;
```

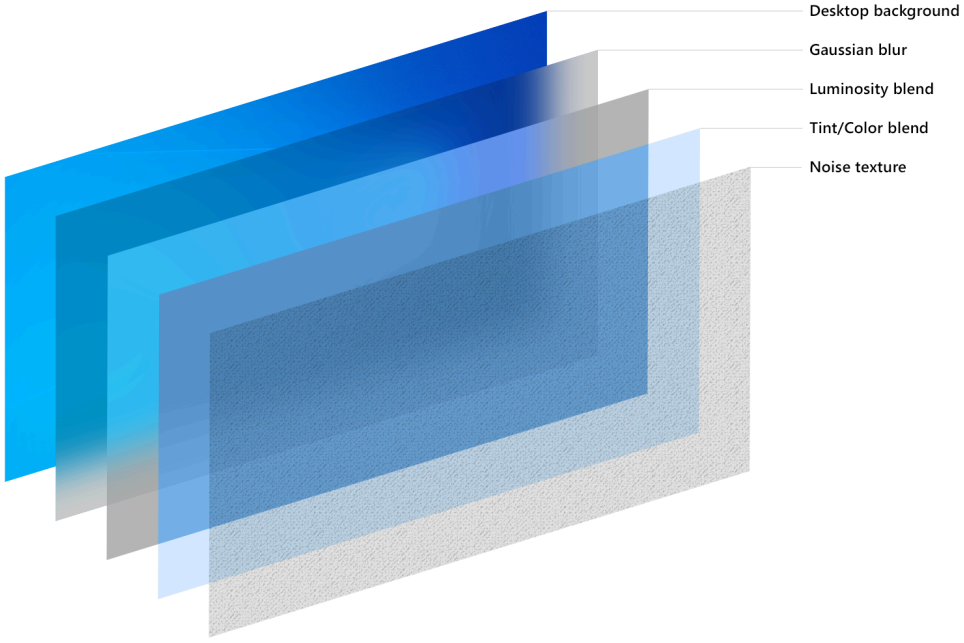
Do's and don'ts

- **Do** use acrylic on transient surfaces.
- **Do** extend acrylic to at least one edge of your app to provide a seamless experience by subtly blending with the app's surroundings.
- **Don't** put desktop acrylic on large background surfaces of your app.

- **Don't** place multiple acrylic panes next to each other because this results in an undesirable visible seam.
- **Don't** place accent-colored text over acrylic surfaces.

How we designed acrylic

We fine-tuned acrylic's key components to arrive at its unique appearance and properties. We started with translucency, blur, and noise to add visual depth and dimension to flat surfaces. We added an exclusion blend mode layer to ensure contrast and legibility of UI placed on an acrylic background. Finally, we added color tint for personalization opportunities. In concert these layers add up to a fresh, usable material.



The acrylic recipe: background, blur, exclusion blend, color/tint overlay, noise

Examples

Open the WinUI 3 Gallery app and see background Acrylic in action

Open the WinUI 3 Gallery app and see the in-app AcrylicBrush in action

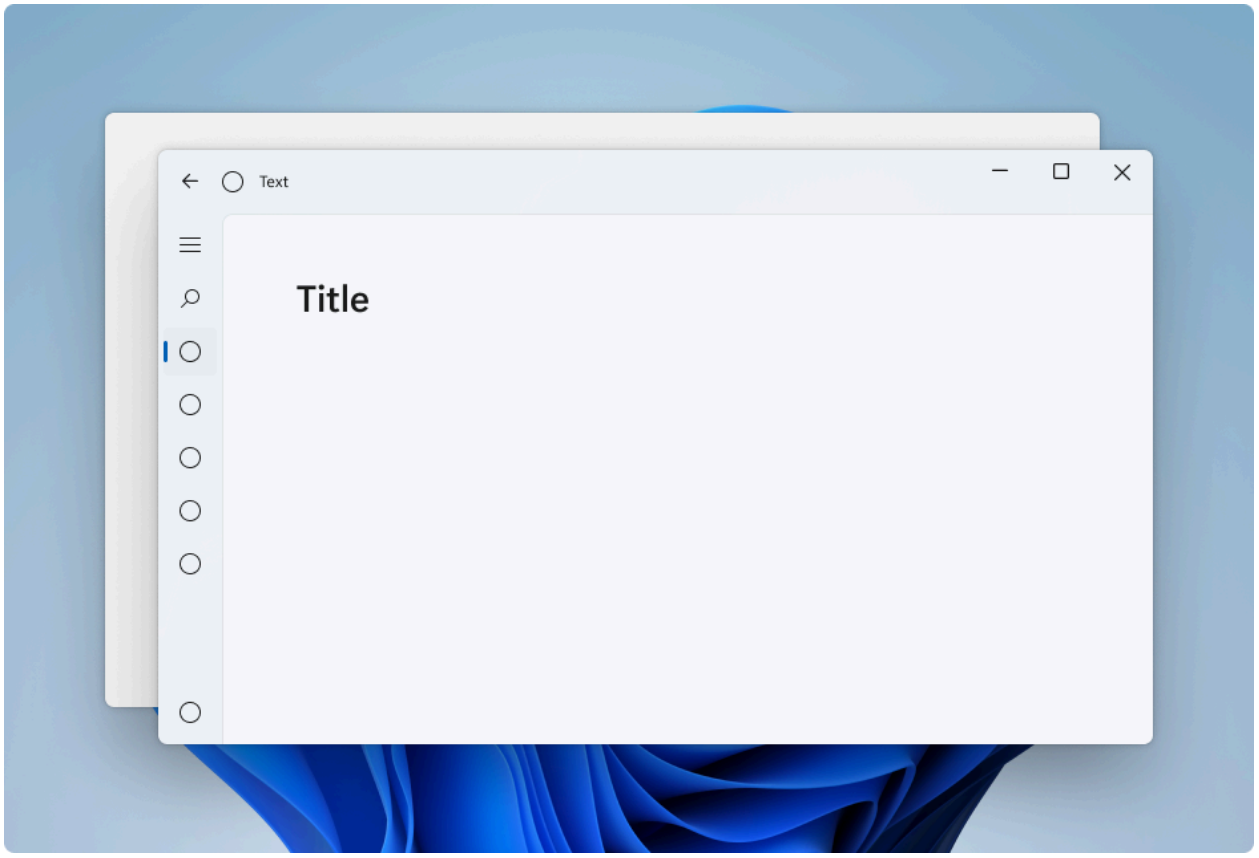
Fluent Design overview

Mica material

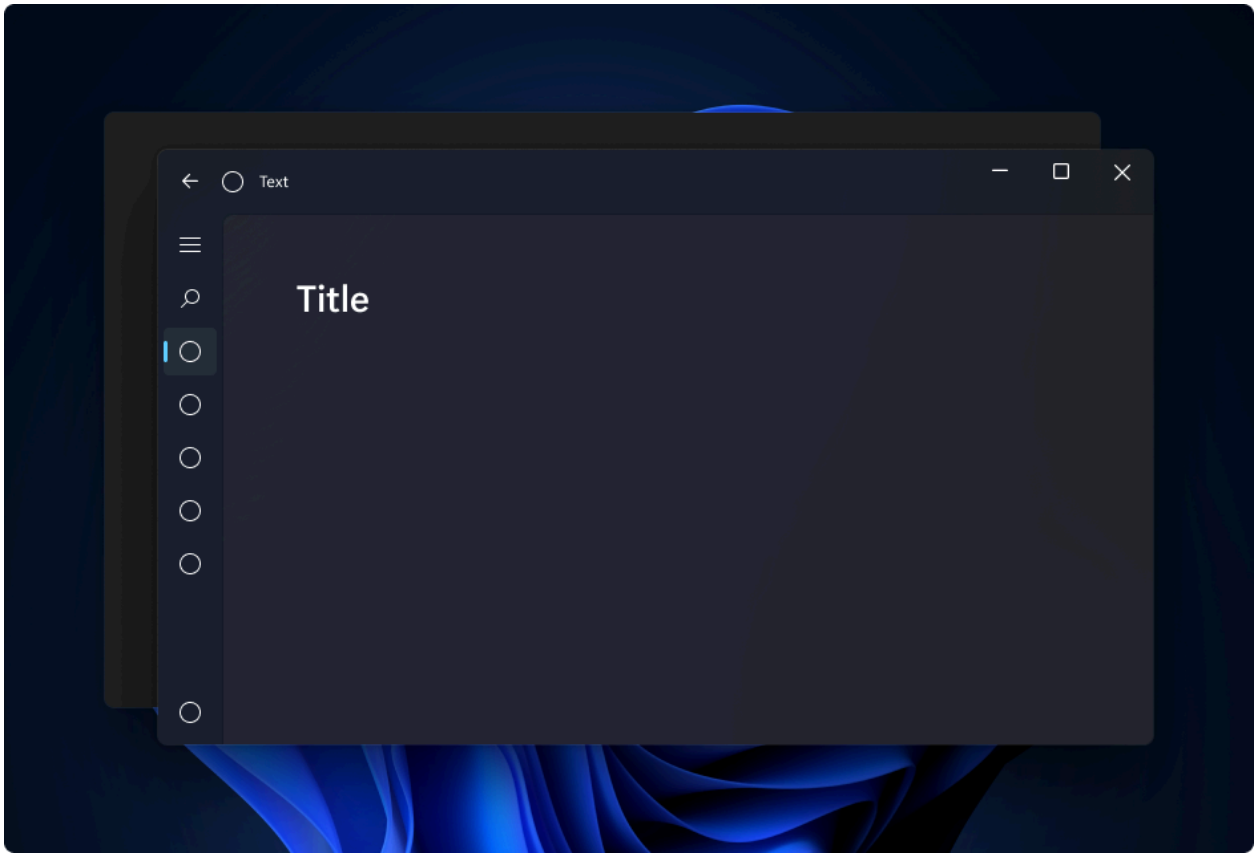
Article • 11/21/2024

Mica is an opaque, dynamic material that incorporates theme and desktop wallpaper to paint the background of long-lived windows such as apps and settings. You can apply Mica to your application backdrop to delight users and create visual hierarchy, aiding productivity, by increasing clarity about which window is in focus. Mica is specifically designed for app performance as it only samples the desktop wallpaper once to create its visualization. Mica is available for UWP apps that use WinUI 2 and apps that use Windows App SDK 1.1 or later, while running on Windows 11 version 22000 or later.

Mica in light theme



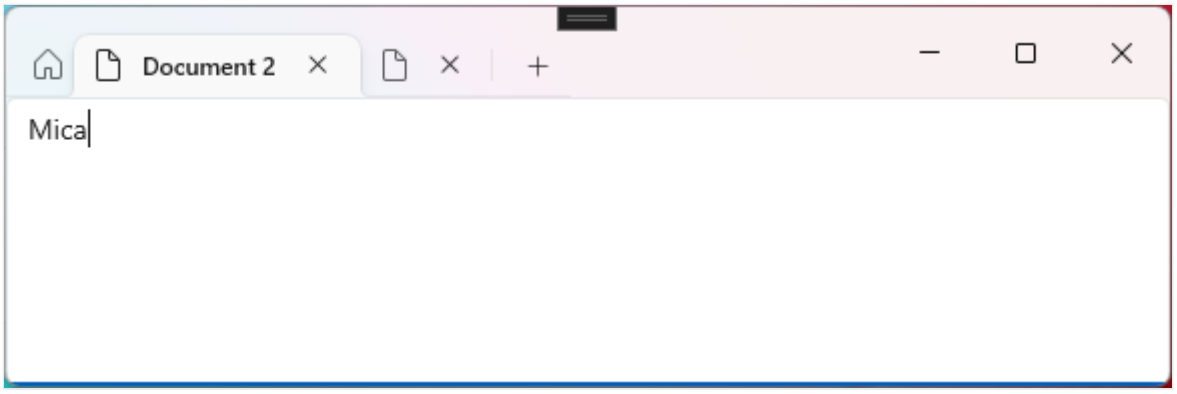
Mica in dark theme

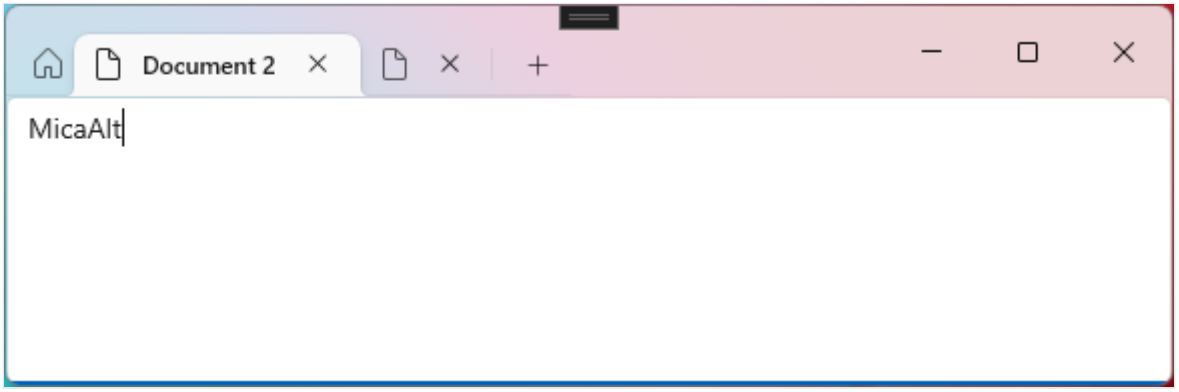


Mica Alt is a variant of Mica, with stronger tinting of the user's desktop background color. You can apply Mica Alt to your app's backdrop to provide a deeper visual hierarchy than Mica, especially when creating an app with a tabbed title bar. Mica Alt is

available for apps that use Windows App SDK 1.1 or later, while running on Windows 11 version 22000 or later.

These images show the difference between Mica and Mica Alt in a title bar with tabs. The first image uses Mica and the second image uses Mica Alt.





When to use Mica or Mica Alt

Mica and Mica Alt are materials that appear on the backdrop of your application — behind all other content. Each material is opaque and incorporates the user's theme and desktop wallpaper to create its highly personalized appearance. As the user moves the window across the screen, the Mica material dynamically adapts to create a rich visualization using the wallpaper underneath the application. In addition, the material helps users focus on the current task by falling back to a neutral color when the app is inactive.

We recommend that you apply Mica or Mica Alt as the base layer of your app, and prioritize visibility in the title bar area. For more specific layering guidance see Layering and Elevation and the App layering with Mica section of this article.

Usability and adaptability

The Mica materials automatically adapt their appearance for a wide variety of devices and contexts. They are designed for performance as they capture the background

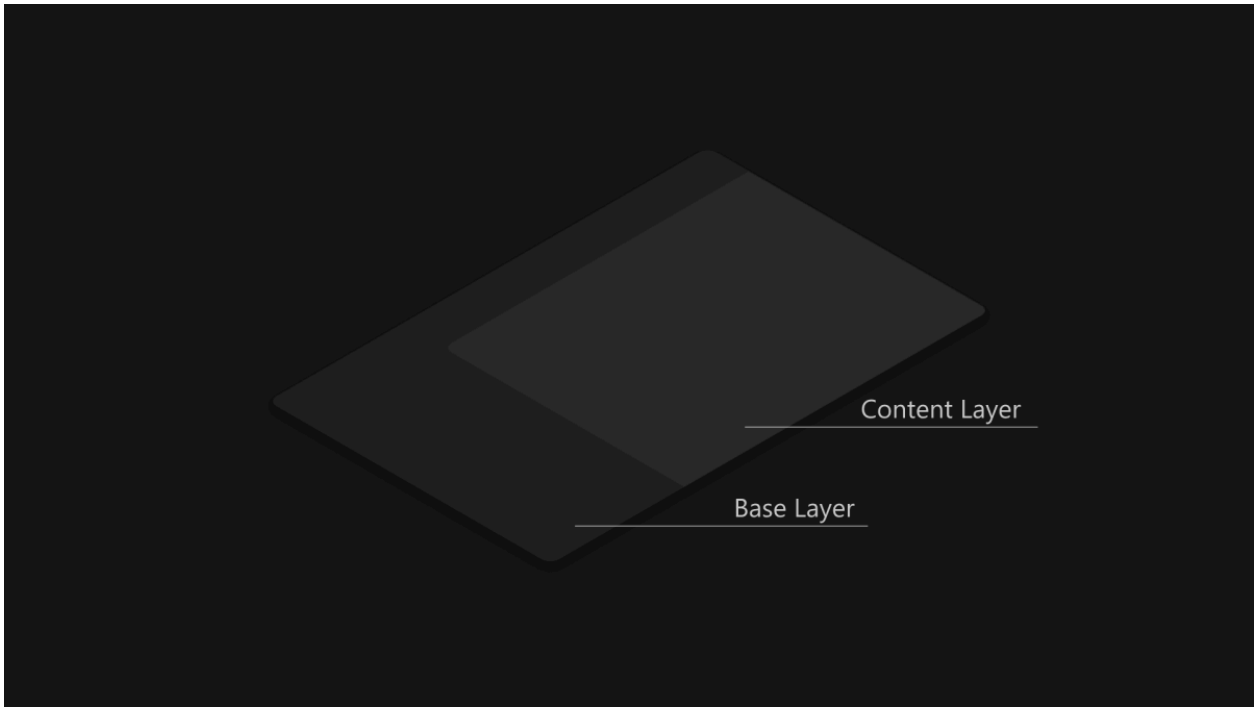
wallpaper only once to create their visualizations.

In High Contrast mode, users continue to see the familiar background color of their choosing in place of Mica or Mica Alt. In addition, the Mica materials will appear as a solid fallback color (`SolidBackgroundFillColorBase` for Mica, `SolidBackgroundFillColorBaseAlt` for Mica Alt) when:

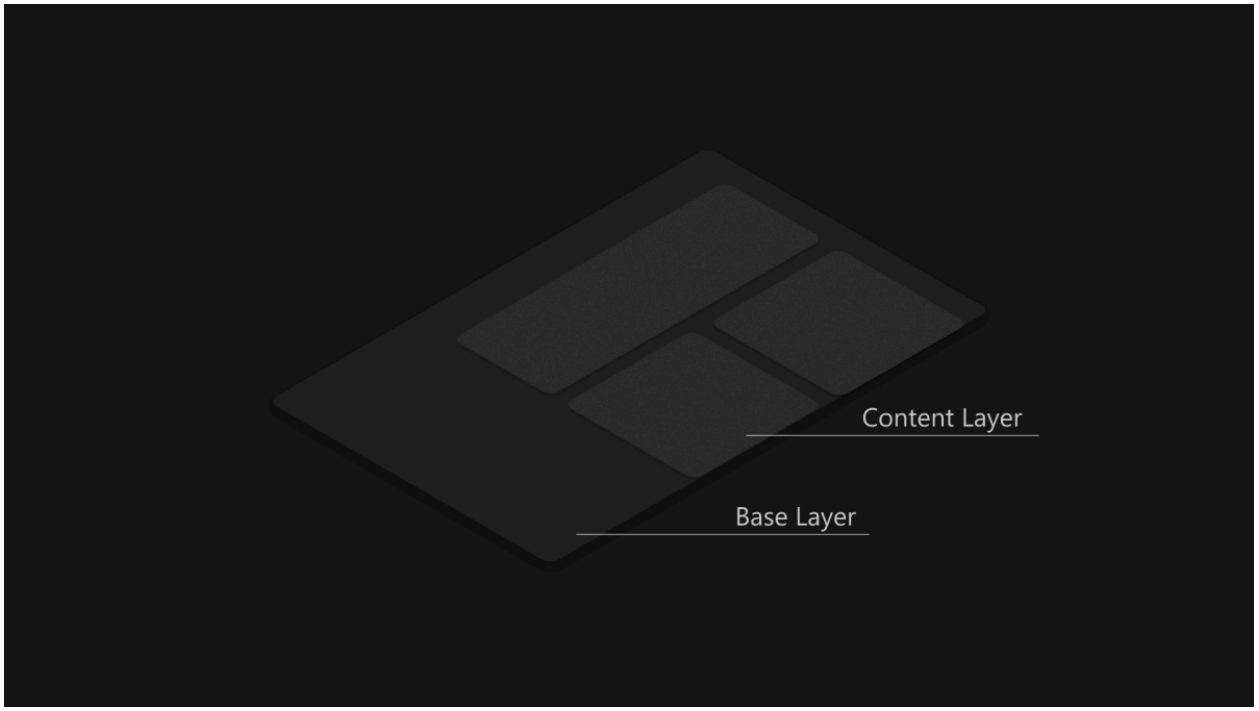
- The user turns off transparency in Settings > Personalization > Color.
- Battery Saver mode is activated.
- The app runs on low-end hardware.
- An app window on desktop deactivates.
- The Windows app is running on Xbox or HoloLens.
- The Windows version is below 22000.

App layering with Mica

Standard pattern content layer



Card pattern content layer



Mica is ideal as a foundation layer in your app's hierarchy due to its inactive and active states and subtle personalization. To follow the two-layer Layering and Elevation system, we encourage you to apply Mica as the base layer of your app and add an additional content layer that sits on top of the base layer. The content layer should pick up the material behind it, Mica, using the `LayerFillColorDefaultBrush`, a low-opacity solid color, as its background. Our recommended content layer patterns are:

- **Standard pattern**: A contiguous background for large areas that need a distinct hierarchical differentiation from the base layer. The `LayerFillColorDefaultBrush` should be applied to the container backgrounds of your WinUI app surfaces (e.g. Grids, StackPanels, Frames, etc.).
- **Card pattern**: Segmented cards for apps that are designed with multiple sectioned and discontinuous UI components. For the definition of the card UI using the `LayerFillColorDefaultBrush`, see Layering and Elevation guidance.

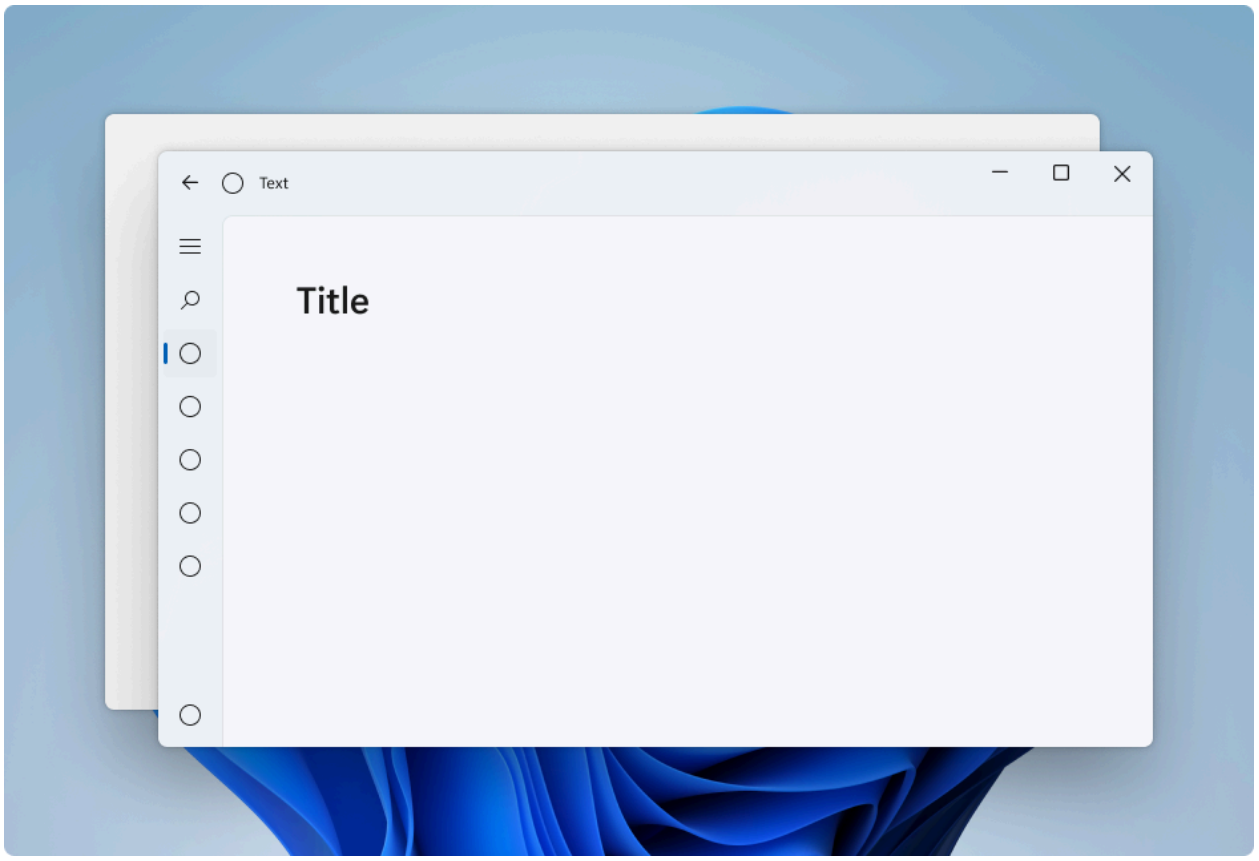
To give your app's window a seamless look, Mica should be visible in the title bar if you choose to apply the material to your app. You can show Mica in the title bar by extending your app into the non-client area and creating a transparent custom title bar. For more info, see Title bar.

The following examples showcase common implementations of the layering strategy with NavigationView where Mica is visible in the title bar area.

- Standard pattern in Left NavigationView.
- Standard pattern in Top NavigationView.
- Card pattern in Left NavigationView.

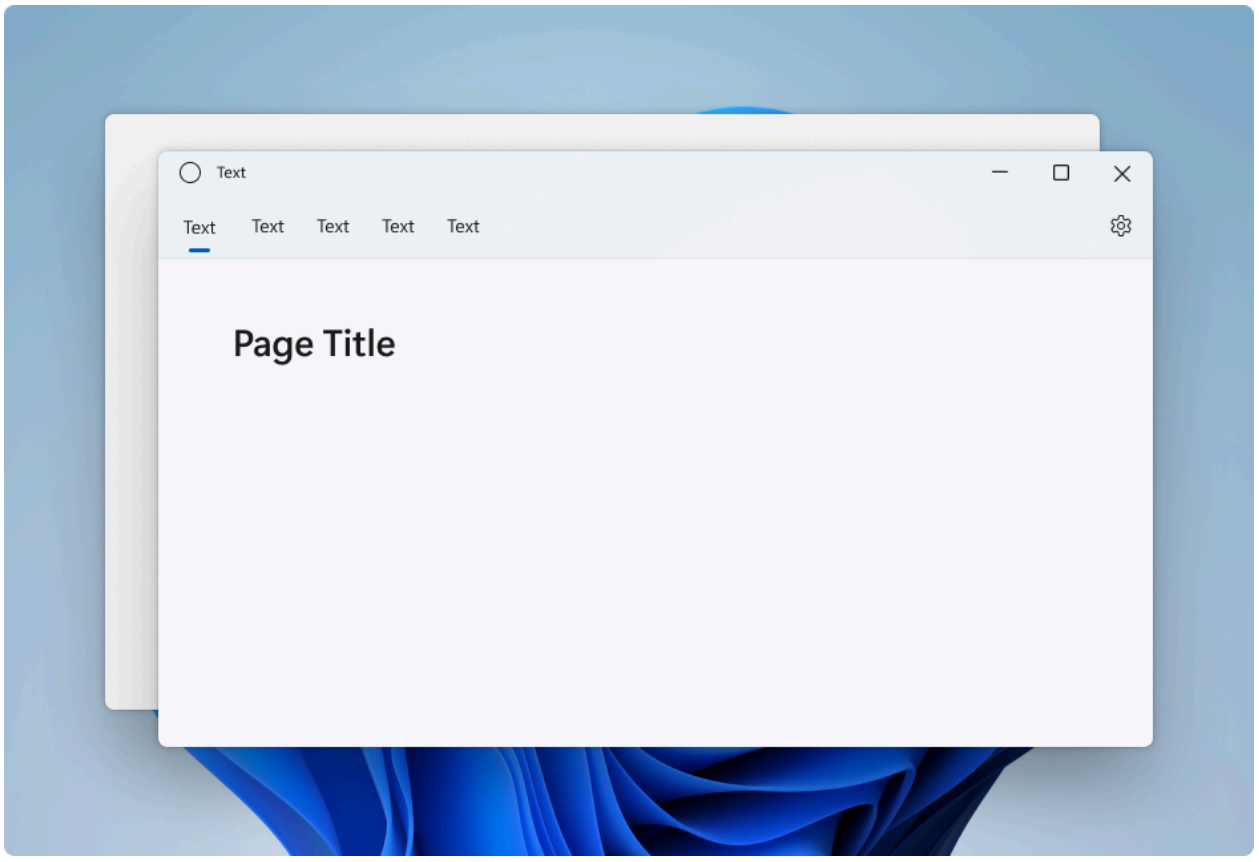
Standard pattern in Left NavigationView

By default, NavigationView in Left mode includes the content layer in its content area. This example extends Mica into the title bar area and creates a custom title bar.



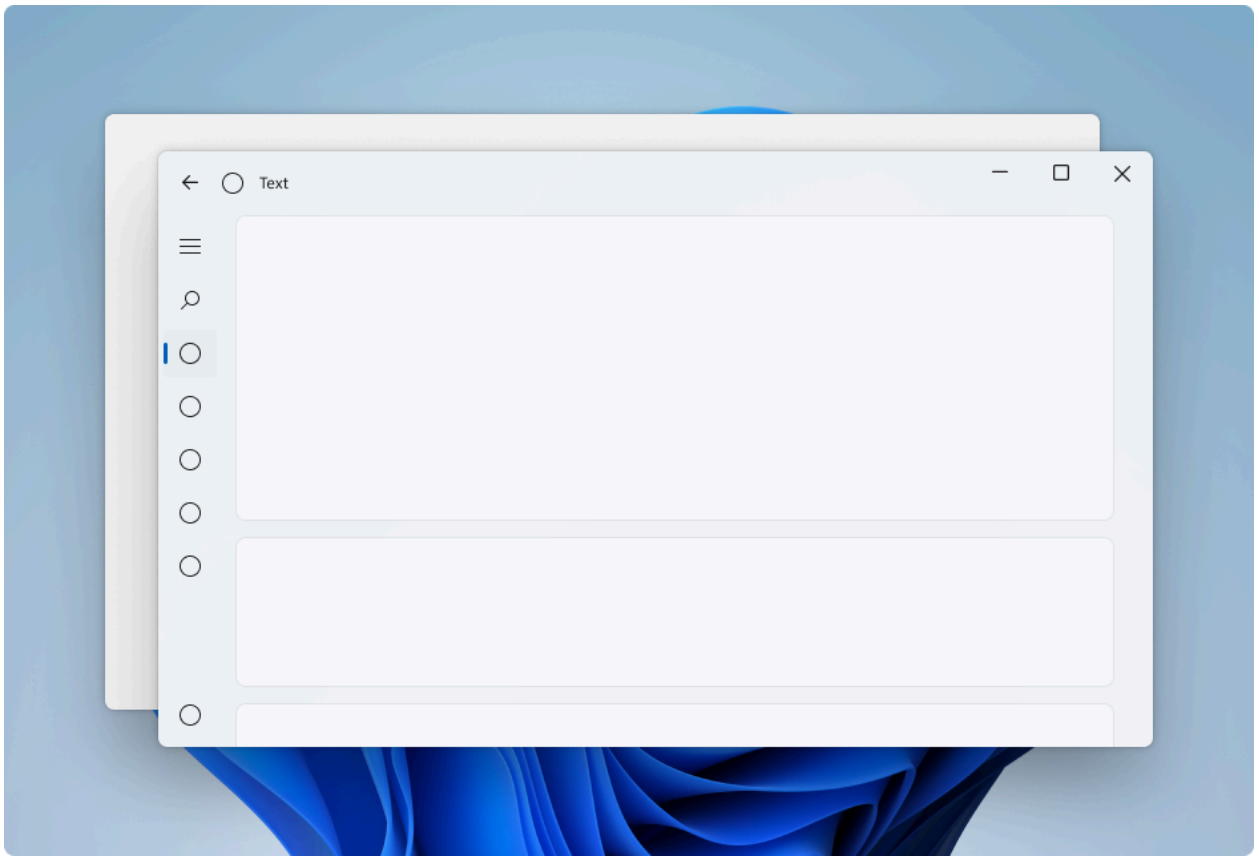
Standard pattern in Top NavigationView

By default, NavigationView in Top mode includes the content layer in its content area. This example extends Mica into the title bar area and creates a custom title bar.



Card pattern in Left NavigationView

To follow the card pattern using a NavigationView you will need to remove the default content layer by overriding the background and border theme resources. Then, you can create the cards in the content area of the control. This example creates several cards, extends Mica into the title bar area, and creates a custom title bar. For more information on card UI, see Layering and Elevation guidance.



App layering with Mica Alt

Mica Alt is an alternative to Mica as a foundation layer in your app's hierarchy with the same features like inactive and active states and subtle personalization. We encourage you to apply Mica Alt as the base layer of your app when you need contrast between title bar elements and the commanding areas of your app (e.g. navigation, menus).

A common scenario for using Mica Alt is when you are creating an application with a tabbed title bar. To follow the Layering and Elevation guidance we encourage you to apply Mica Alt as the base layer of your app, add a commanding layer that sits on top of the base layer, and finally add an additional content layer that sits on top of the commanding layer. The commanding layer should pick up the material behind it, Mica Alt, using the `LayerOnMicaBaseAltFillColorDefaultBrush`, a low-opacity solid color, as its background. The content layer should pick up the layers below it, using the `LayerFillColorDefaultBrush`, another low-opacity solid color. The layer system is as follows:

- **Mica Alt**: The base layer.
- **Commanding layer**: Requires distinct hierarchical differentiation from the base layer. The `LayerOnMicaBaseAltFillColorDefaultBrush` should be applied to the commanding areas of your WinUI app surfaces (e.g. MenuBar, navigation structure, etc.)

- **Content layer**: A contiguous background for large areas that need a distinct hierarchical differentiation from the commanding layer. The `LayerFillColorDefaultBrush` should be applied to the container backgrounds of your WinUI app surfaces (e.g. Grids, StackPanels, Frames, etc.).

To give your app's window a seamless look, Mica Alt should be visible in the title bar if you choose to apply the material to your app. You can show Mica Alt in the title bar by extending your app into the non-client area and creating a transparent custom title bar.

Recommendations

- **Do** set the background to *transparent* for all layers where you want to see Mica so the Mica shows through.
- **Don't** apply backdrop material more than once in an application.
- **Don't** apply backdrop material to a UI element. The backdrop material will not appear on the element itself. It will only appear if all layers between the UI element and the window are set to transparent.

Examples

Open the WinUI 3 Gallery app and see Mica in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

How to use Mica

You can use Mica in UWP apps that use WinUI 2, or in apps that use Windows App SDK 1.1 or later. You can use Mica Alt in apps that use Windows App SDK 1.1 or later.

Use Mica with the Windows App SDK

To use Mica in a WinUI 3 XAML app, see Apply Mica or Acrylic materials in desktop apps for Windows 11.

To use Mica in a Win32 app, see Apply Mica in Win32 desktop apps for Windows 11.

Use Mica with WinUI 2 for UWP

To use Mica in a UWP app with WinUI 2, see Apply Mica with WinUI 2 for UWP.

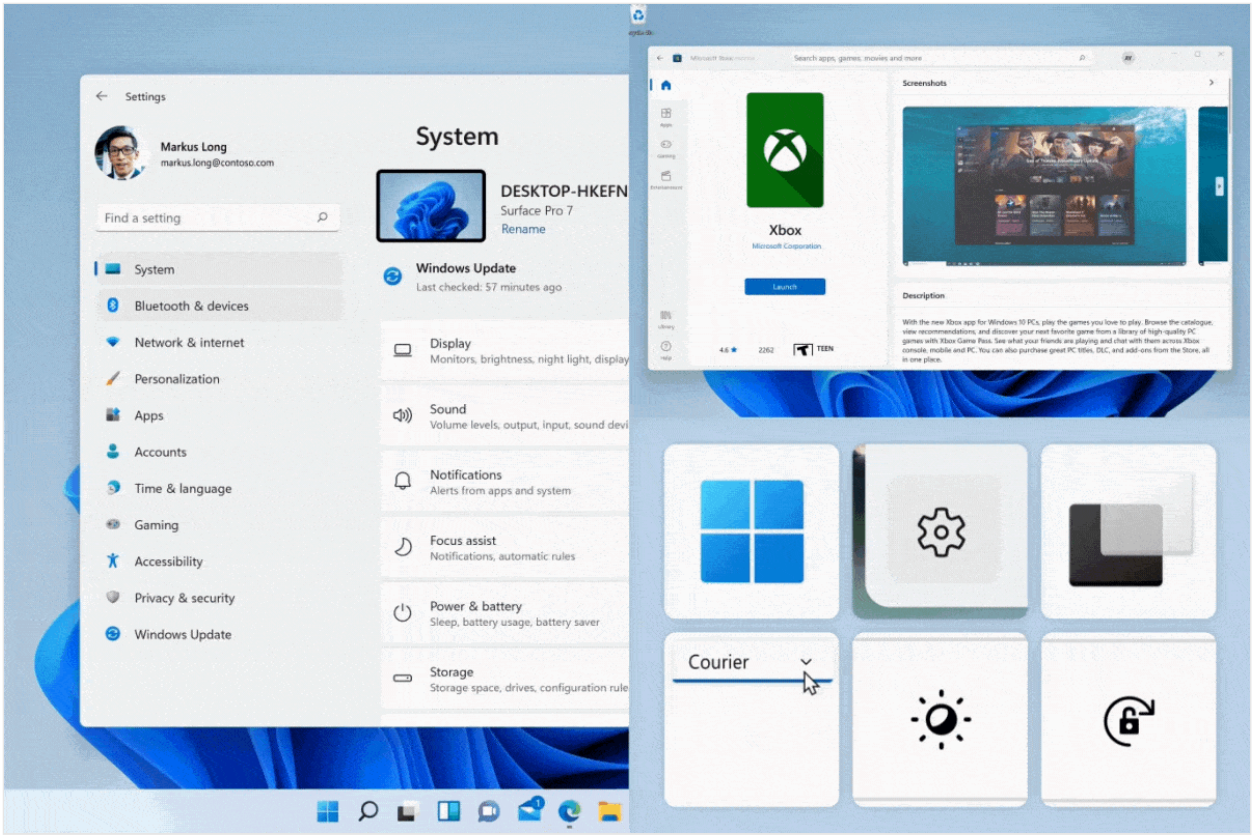
Motion in Windows

Article • 11/05/2024

Motion describes the way the interface animates and responds to user interaction. Motion in Windows is reactive, direct, and context appropriate. It provides feedback to user input and reinforces spatial paradigms that support way-finding.



> **Tip**
>
> This article describes how the Fluent Design language is applied to Windows apps. For more information, see Fluent Design - Motion.

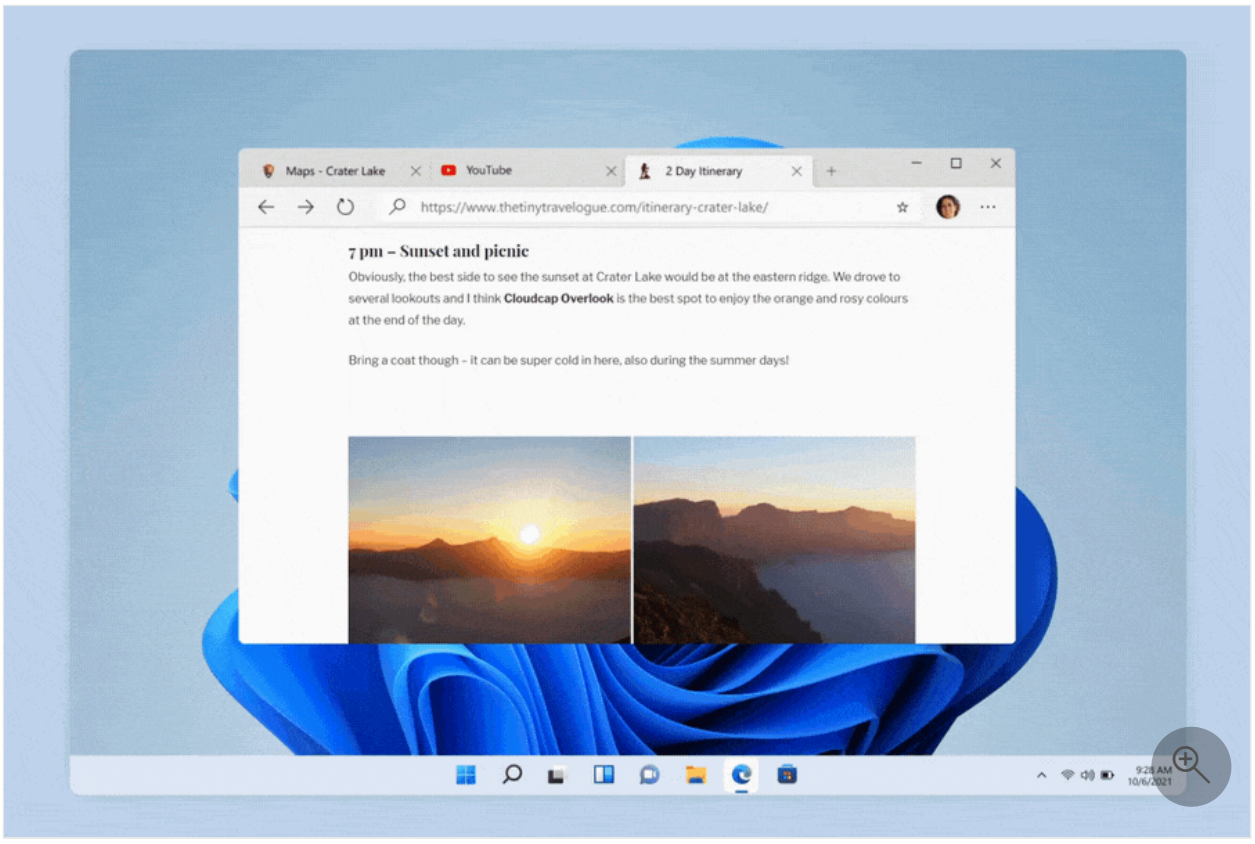
Motion principles

These principles guide the use of motion in Windows.

Connected: Elements of actions connect seamlessly

Elements that change position and size should visually connect from one state to another, even if they aren't connected under the hood. Users are guided to follow elements going from point to point, lowering the cognitive load of static state changes.

Example: When a window transitions between floating, snapped, and maximized, it always feels like the same window.

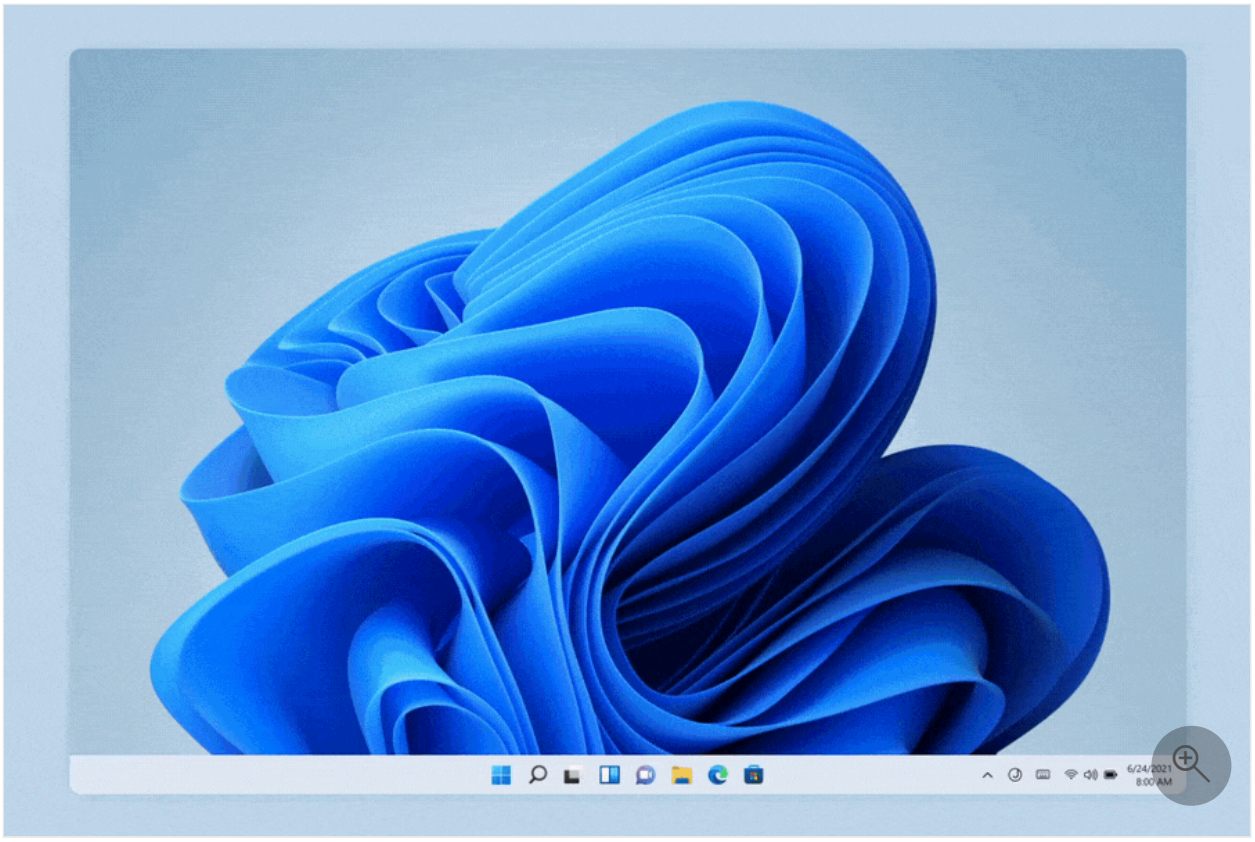


> **Tip**
>
> To improve accessibility and readability, this page uses still images in the default view. You can click an image to see the animated version.

Consistent: Elements should behave in similar ways when sharing entry points

Surfaces that share the same UI entry point should invoke and dismiss the same way to bring consistency to interactions. Each transition should respect the timing, easing, and direction of other elements so a surface feels cohesive.

Example: All taskbar flyouts slide up when invoked, and slide down when dismissed.

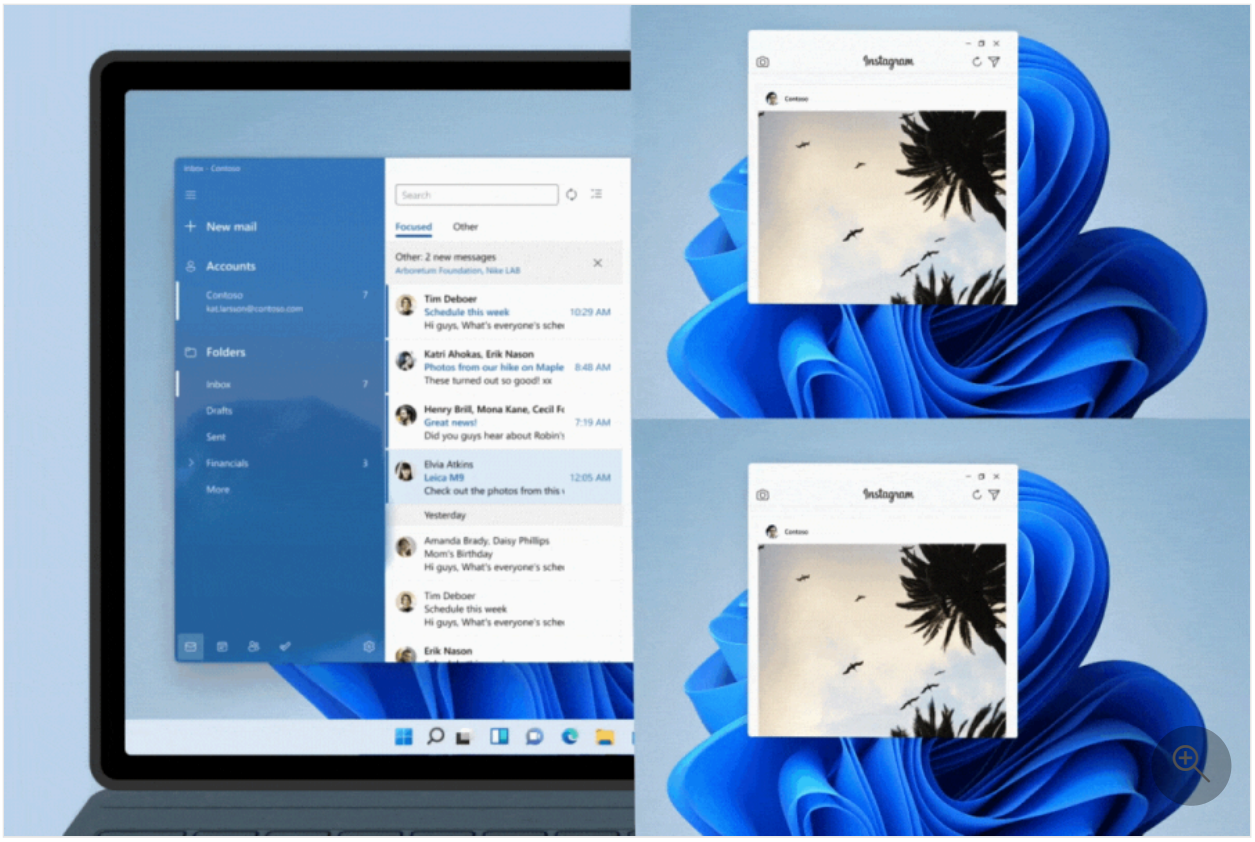


Click the image to see it animated.

Responsive: The system responds and adapts to user input and choices

Clear indicators show the system recognizes and adapts gracefully to different input, postures, and orientations. Apps should build on OS behaviors to feel responsive, alive, and aid usage depending on input methods.

Example: Taskbar icons spread out when keyboards are detached. Window edges invoke a different visual depending on cursor or touch input.

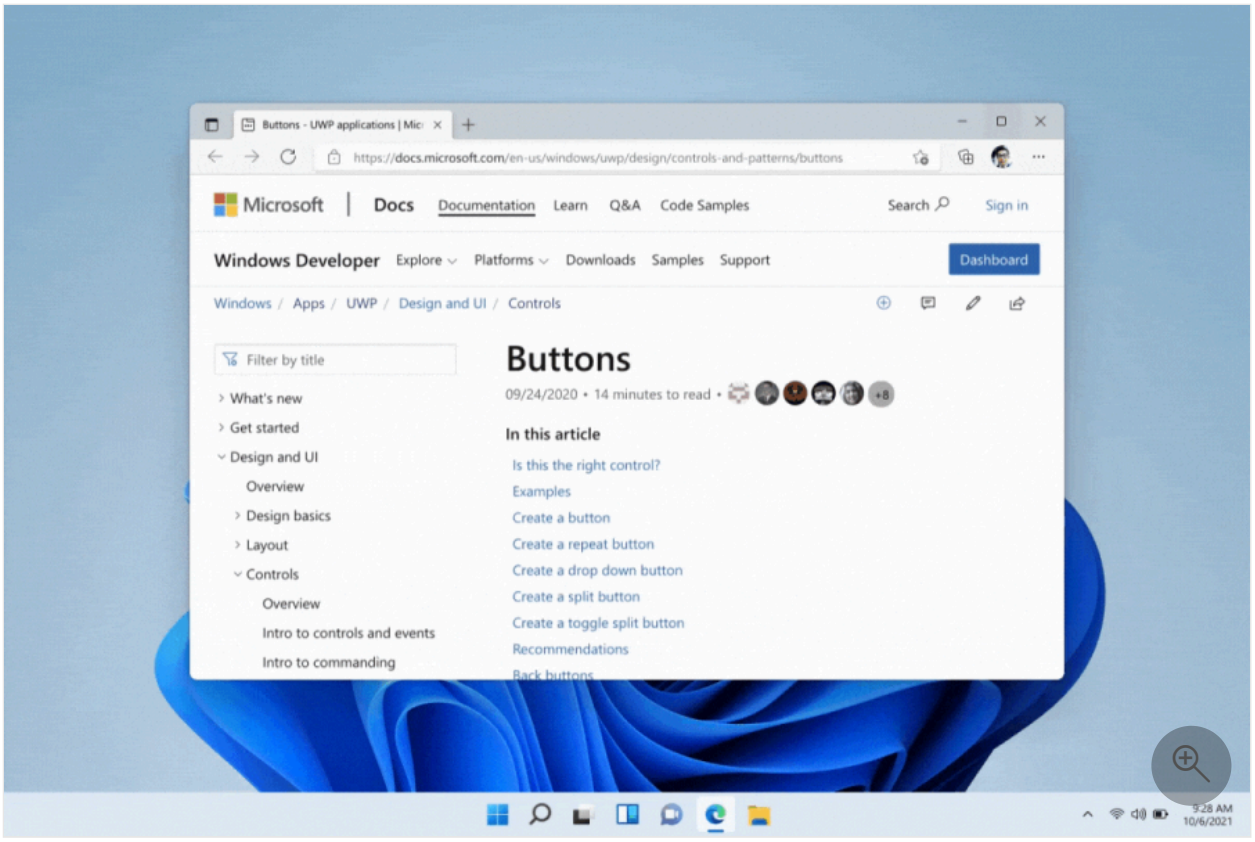


Click the image to see it animated.

Delightful: Unexpected moments of joy with purpose

Motion adds personality and energy to the experience in order to transform simple actions into moments of delight. These moments are always brief and fleeting, and help reinforce user actions.

Example: Minimizing a window causes an app icon to bounce down, while restoring bounces an app icon up.

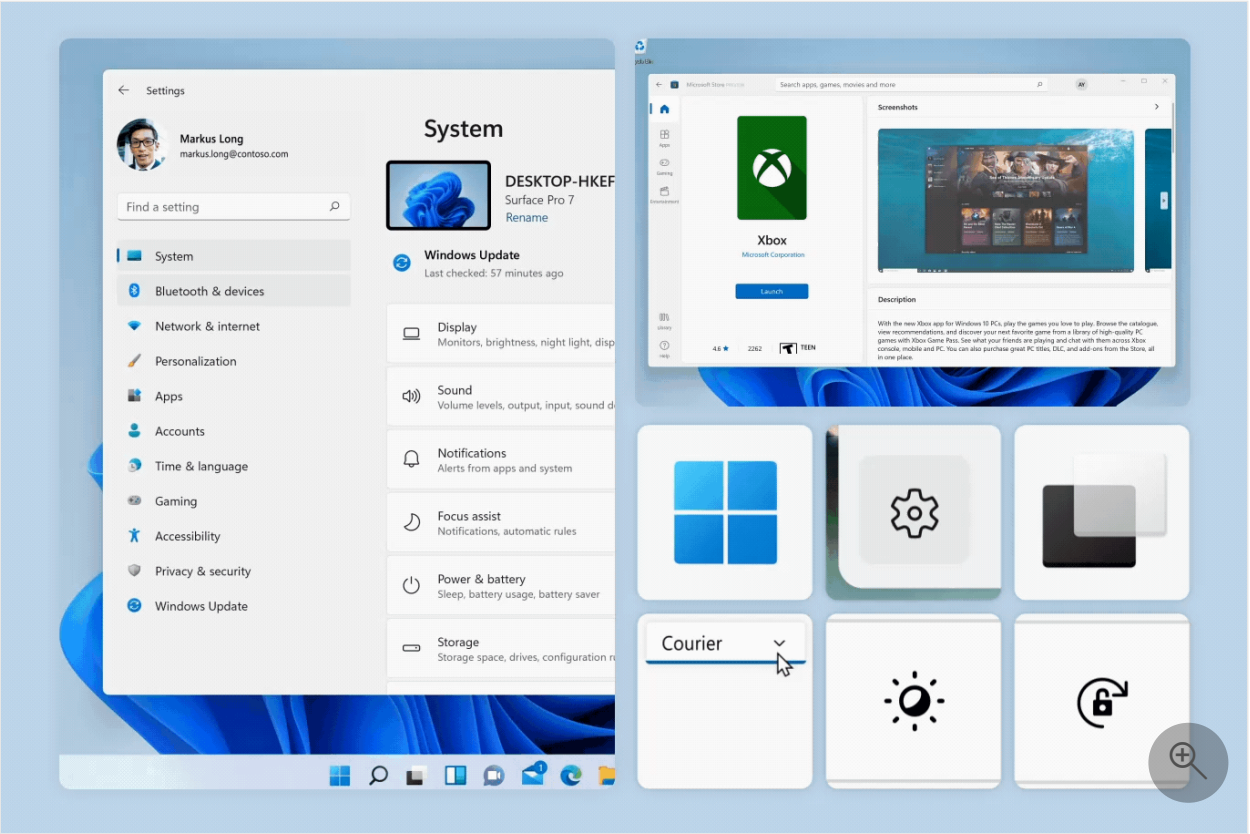


Click the image to see it animated.

Resourceful: Utilizes existing controls to bring consistency where possible

Avoid custom animations where possible. Use animation resources like WinUI controls for page transitions, in-page focus, and micro interactions. If you can't use WinUI controls, mimic existing OS behaviors based on where the app entry point lives.

Example: Page transitions, connected animations, and animated icons are the recommended WinUI controls that add delightful and necessary motion to apps.



Click the image to see it animated.

Examples

Open the WinUI 3 Gallery app and see Motion examples in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

Usage

Animation properties

Windows motion is fast, direct, and context-appropriate. Timing and easing curves are adjusted based on the purpose of the animation to create a coherent experience.

Expand table

Purpose	Definition	Ease	Timing	Used For
Direct Entrance	Fast – In	Cubic-bezier(0,0,0,1)	167, 250, 333	Position, Scale, Rotation

Purpose	Definition	Ease	Timing	Used For
Existing Elements	Point to Point	Cubic-bezier(0.55,0.55,0,1)	167, 250, 333ms	Position, Scale, Rotation
Direct Exit	Fast – Out	Cubic-bezier(0,0,0,1)	167ms	Position, Scale, Rotation (ALWAYS combine with fade out)
Gentle Exit	Soft – Out	Cubic-bezier(1,0,1,1)	167ms	Position, Scale
Bare Minimum	Fade – In + Out	Linear	83ms	Opacity
Strong Entrance	Elastic In (3 Keyframes)	(3 values below)	(3 values below)	Position, Scale
	Keyframe 1	Cubic-Bezier(0.85, 0, 0, 1)	167ms	
	Keyframe 2	Cubic-Bezier(0.85, 0, 0.75, 1)	167ms	
	Keyframe 3	Cubic-Bezier(0.85, 0, 0, 1)	333ms	

Controls

This release of Windows introduces purposeful micro-interactions in WinUI controls. Add these controls to your app to help better organize information, and help your app's users transition from page to page, layer to layer, and state to state of an interaction.

Page Transition: Page-to-page transitions within the same surface

Use page transitions to transition smoothly from page to page, and configure animation directions to respect the flow of an app.

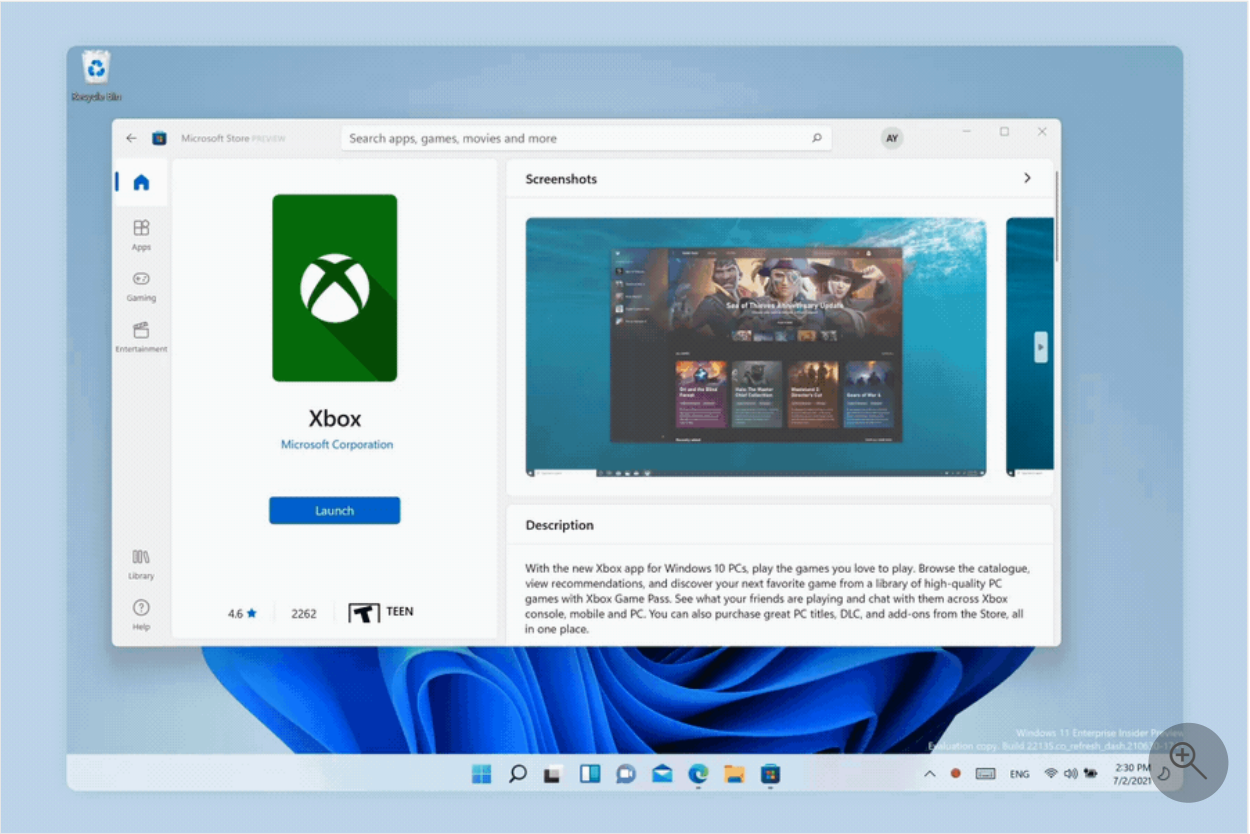
Page transitions guide your user's eyes to incoming and outgoing content, lowering cognitive load.

Click the image to see it animated.

Connected Animation: Layer-to-layer transitions within the same page

Use connected animations to highlight specific pieces of information within a page or surface, while retaining context.

Connected animations give focus to selected elements, and seamlessly transition between the focused and non-focused states.

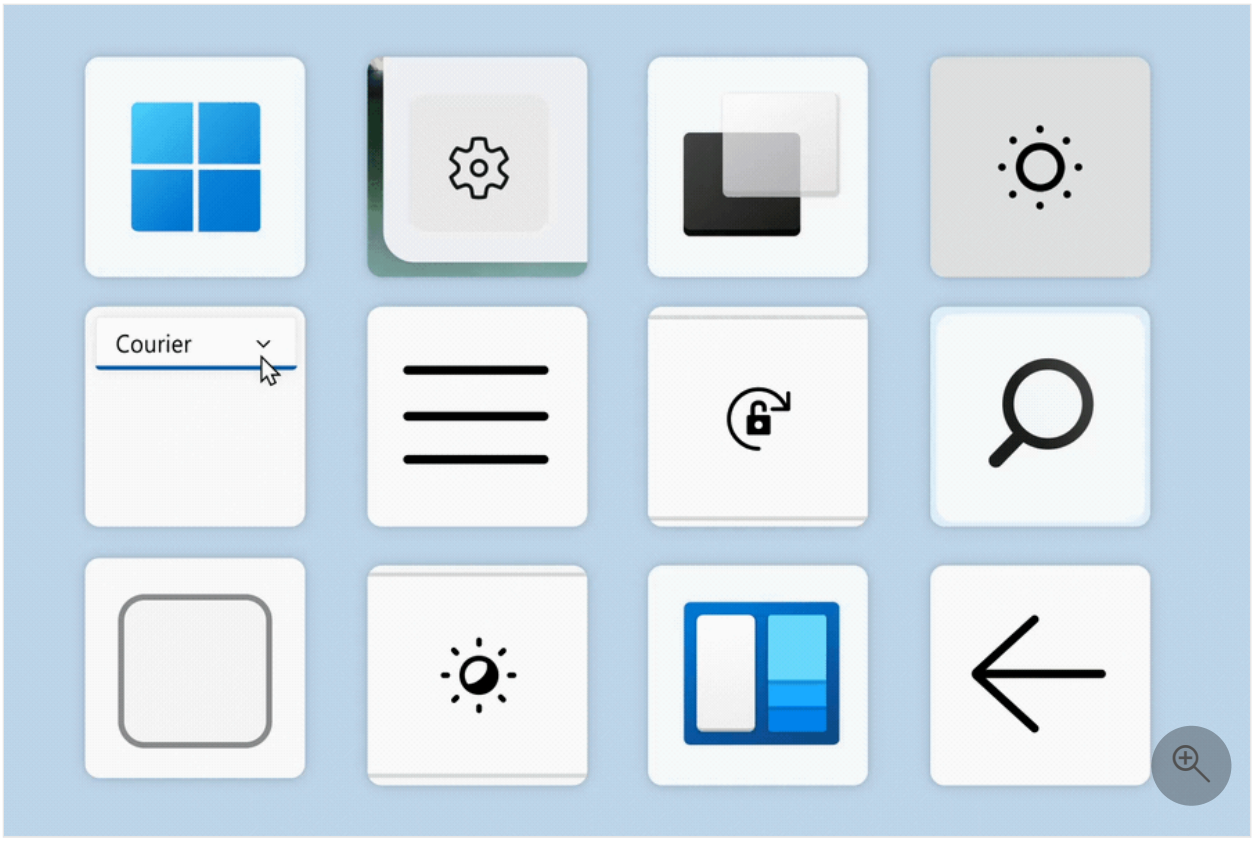


Click the image to see it animated.

Animated Icon: Adds delight and reveals information through micro interactions

Use animated icons to implement lightweight, vector-based icons and illustrations with motion using Lottie animations.

Animated icons draw attention to specific entry points, provide feedback from state to state, and add delight to an interaction.



Click the image to see it animated.

Timing and easing

Article • 11/05/2024

While motion is based in the real world, we are also a digital medium, which comes with an expectation of speed and performance.

Examples

Open the WinUI 3 Gallery app and see Easing Functions in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

Standard animation duration values

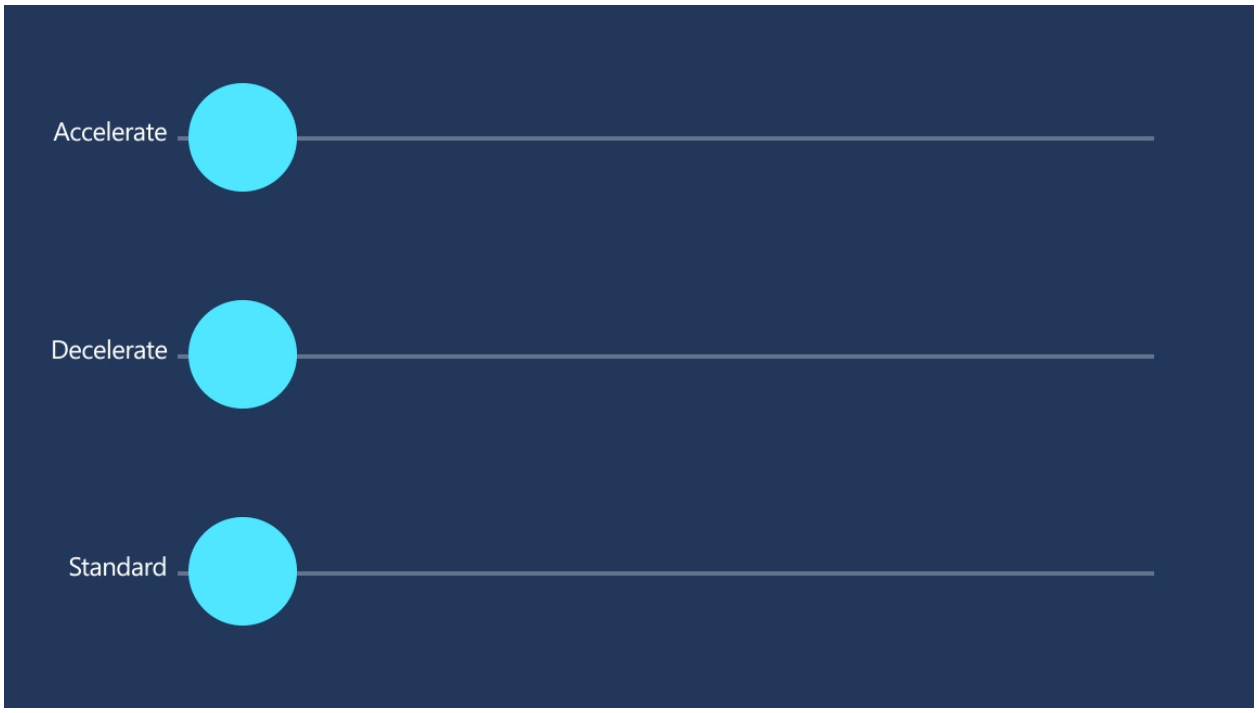
WinUI provides a set of standard animation durations that are used throughout the platform controls. You can use these named resources when building custom Storyboard animations as well.

Expand table

ThemeResource Name	Value
ControlNormalAnimationDuration	250ms
ControlFastAnimationDuration	167ms
ControlFasterAnimationDuration	83ms

Easing in Fluent motion

Easing is a way to manipulate the velocity of an object as it travels. It's the glue that ties together all the Fluent motion experiences. While extreme, the easing used in the system helps unify the physical feel of objects moving throughout the system. This is one way to mimic the real world, and make objects in motion feel like they belong in their environment.



Apply easing to motion

These easings will help you achieve a more natural feel, and are the baseline we use for Fluent motion.

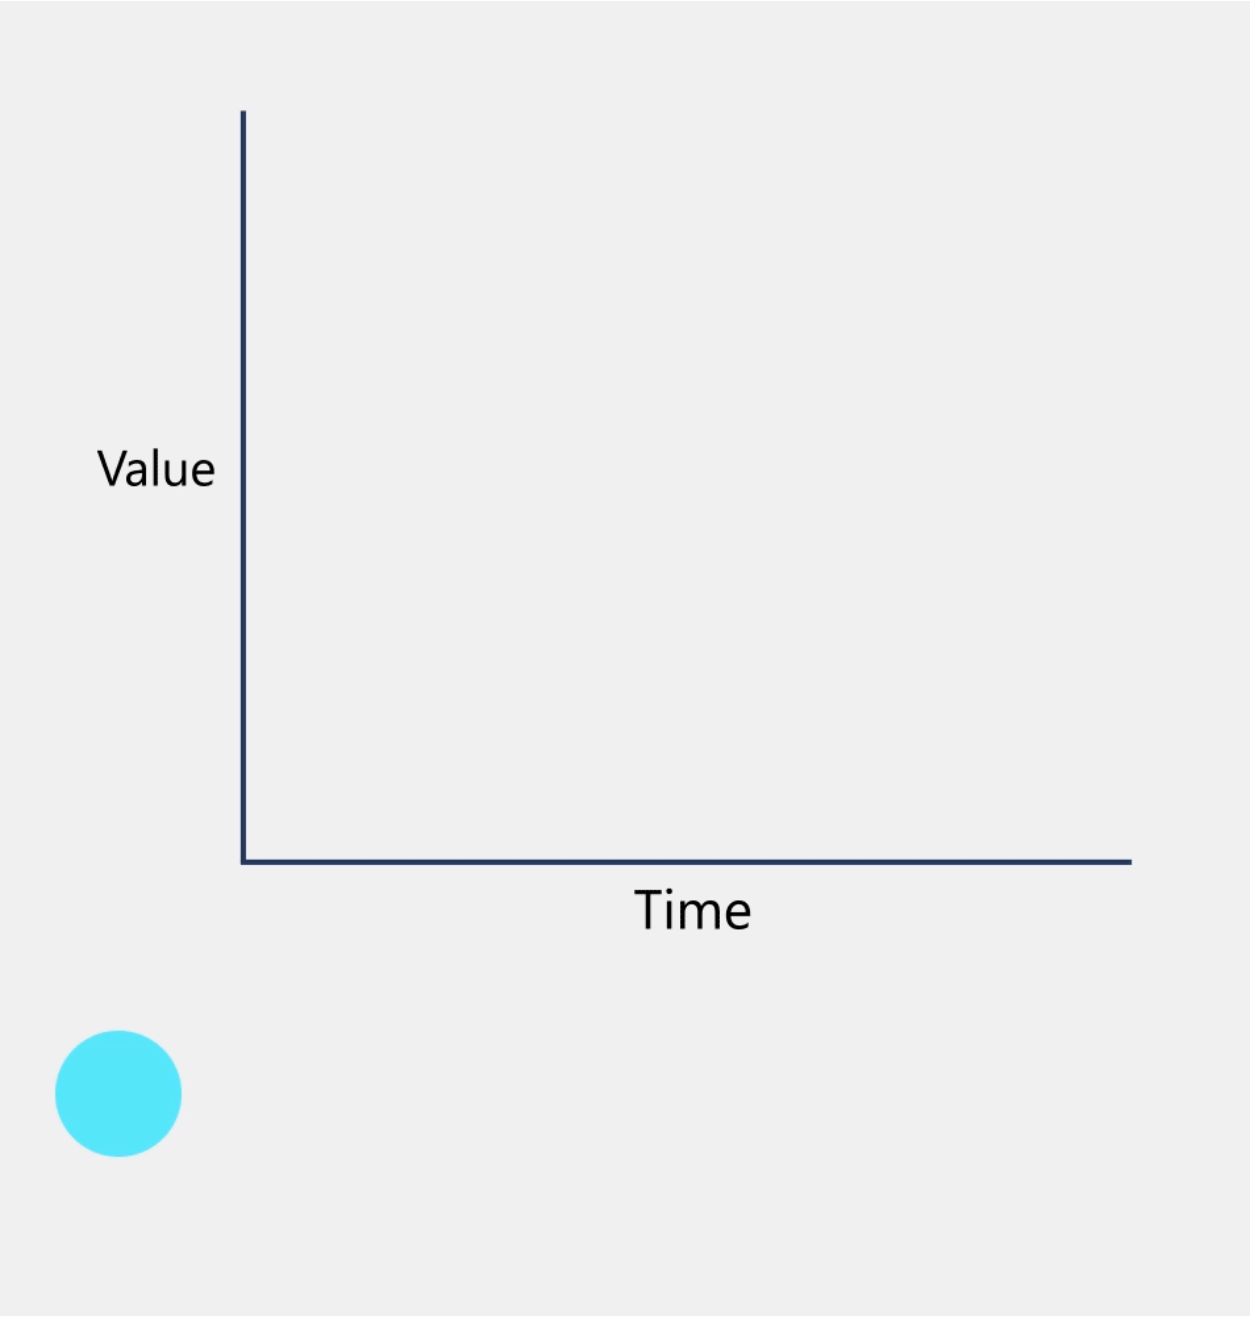
Fast Out, Slow In

```
C#
cubic-bezier(0, 0, 0, 1)
```

Use for objects or UI entering the scene, either navigating or spawning.

Once on-scene, the object is met with extreme friction, which slows the object to rest. The resulting feel is that the object traveled from a long distance away and entered at an extreme velocity, or is quickly returning to a rest state.

Even if it's preceded by a moment of unresponsiveness, the velocity of the incoming object has the effect of feeling fast and responsive.



Slow Out, Fast In

```
C#
cubic-bezier(1 , 0 , 1 , 1)
```

Use for UI or objects that are exiting the scene.

Objects become powered and gain momentum until they reach escape velocity.The resulting feel is that the object is trying its hardest to get out of the user's way and make room for new content to come in.

- Directionality and gravity

Directionality and gravity

Article • 11/05/2024

Directional signals help to solidify the mental model of the journey a user takes across experiences. It is important that the direction of any motion support both the continuity of the space as well as the integrity of the objects in the space.

Directional movement is subject to forces like gravity. Applying forces to movement reinforces the natural feel of the motion.

Direction of movement

Direction of movement corresponds to physical motion. Just like in nature, objects can move in any world axis - X,Y,Z. This is how we think of the movement of objects on the screen. When you move objects, avoid unnatural collisions. Keep in mind where objects come from and go to, and always support higher level constructs that may be used in the scene, such as scroll direction or layout hierarchy.

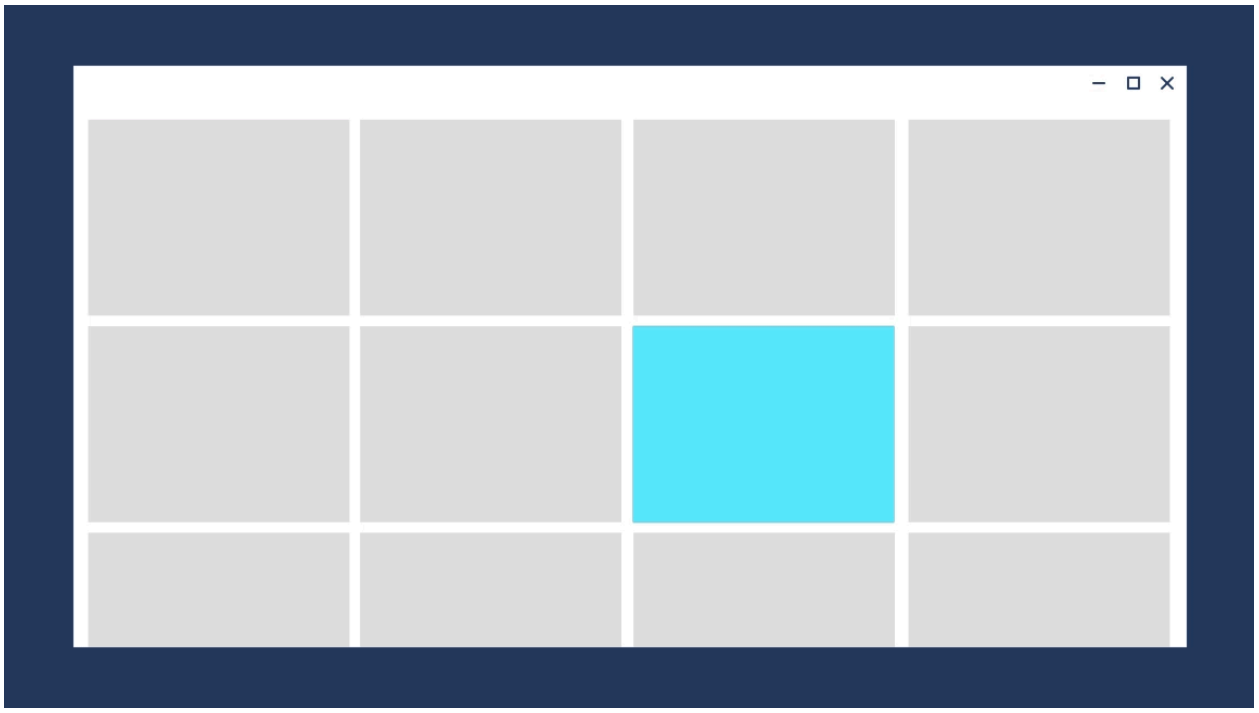
Direction of navigation

The direction of navigation between scenes in your app is conceptual. Users navigate forward and back. Scenes move in and out of view. These concepts combine with physical movement to guide the user.

When navigation causes an object to travel from the previous scene to the new scene, the object makes a simple A-to-B move on the screen. To ensure that the movement feels more physical, the standard easing is added, as well as the feeling of gravity.

For back navigation, the move is reversed (B-to-A). When the user navigates back, they have an expectation to be returned to the previous state as soon as possible. The timing is quicker, more direct, and uses the decelerate easing.

Here, these principles are applied as the selected item stays on screen during forward and back navigation.



When navigation causes items on the screen to be replaced, its important to show where the exiting scene went to, and where the new scene is coming from.

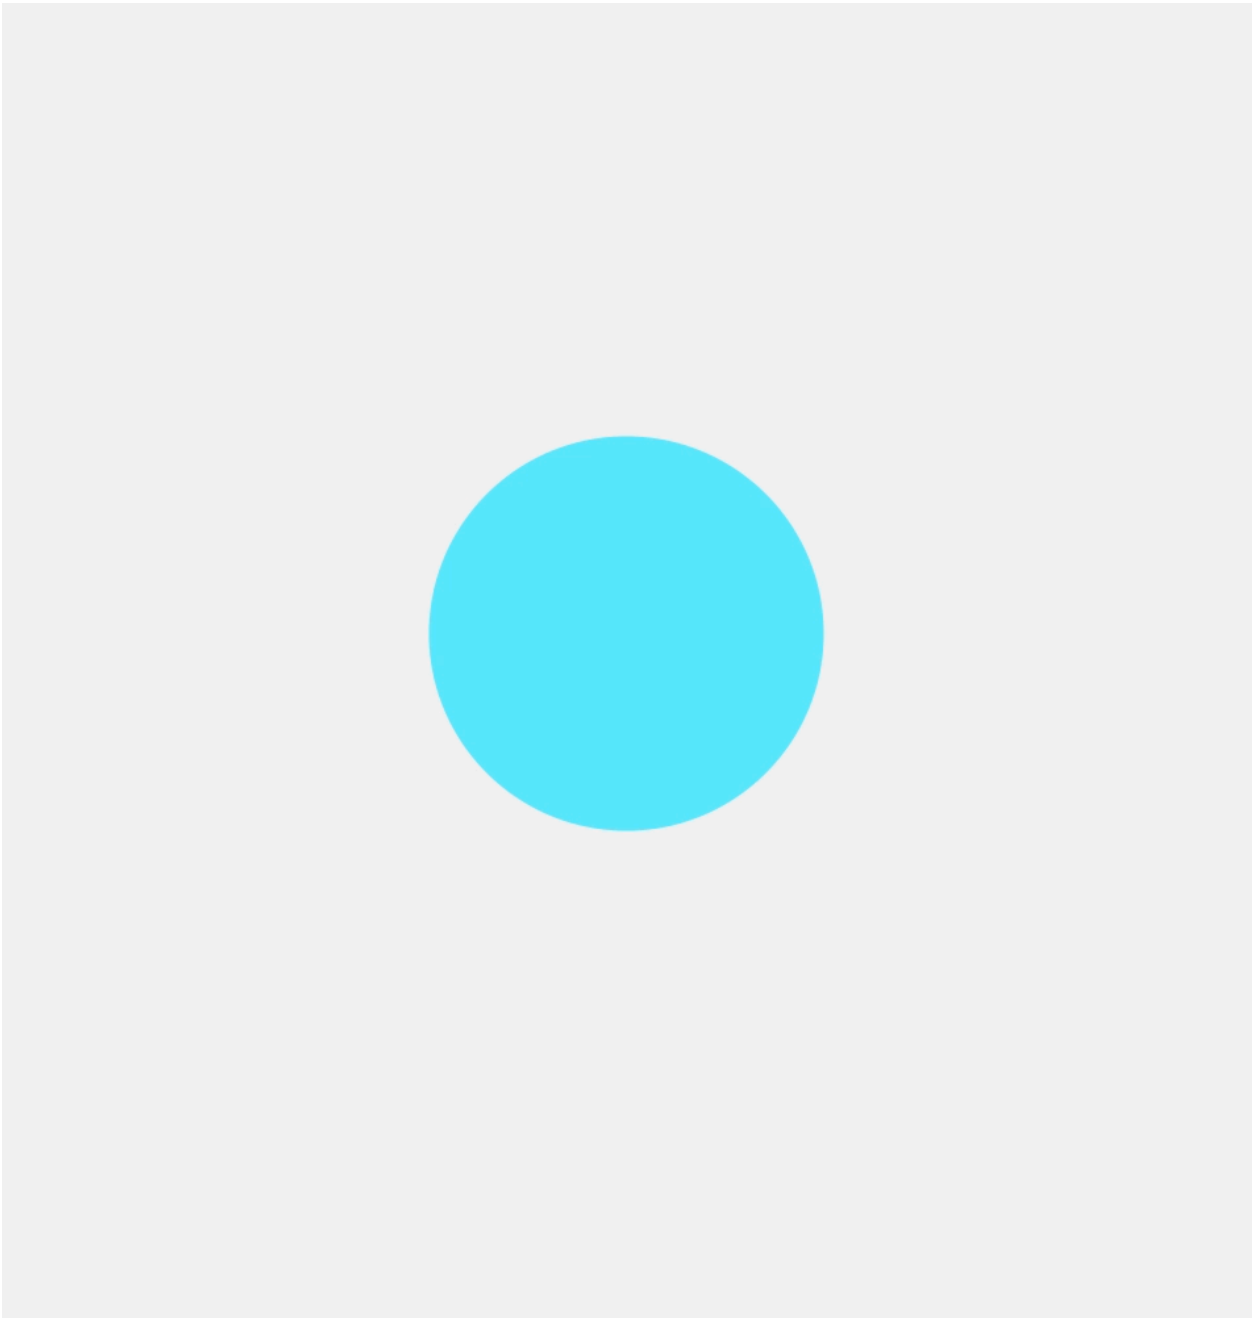
This has several benefits:

- It solidifies the user's mental model of the space.
- The duration of the exiting scene provides more time to prepare content to be animated in for the incoming scene.
- It improves the perceived performance of the app.

There are 4 discreet directions of navigation to consider.

Forward-In Celebrate content entering the scene in a manner that does not collide with outgoing content. Content decelerates into the scene.

Forward-Out Content exits quickly. Objects accelerate off screen.



Backward-In Same as Forward-In, but reversed.

Backward-Out Same as Forward-Out, but reversed.

Gravity

Gravity makes your experiences feel more natural. Objects that move on the Z-axis and are not anchored to the scene by an onscreen affordance have the potential to be affected by gravity. As an object breaks free of the scene and before it reaches escape velocity, gravity pulls down on the object, creating a more natural curve of the object trajectory as it moves.

Gravity typically manifests when an object must jump from one scene to another. Because of this, connected animation uses the concept of gravity.

Here, an element in the top row of the grid is affected by gravity, causing it to drop slightly as it leaves its place and moves to the front.

Bringing it together

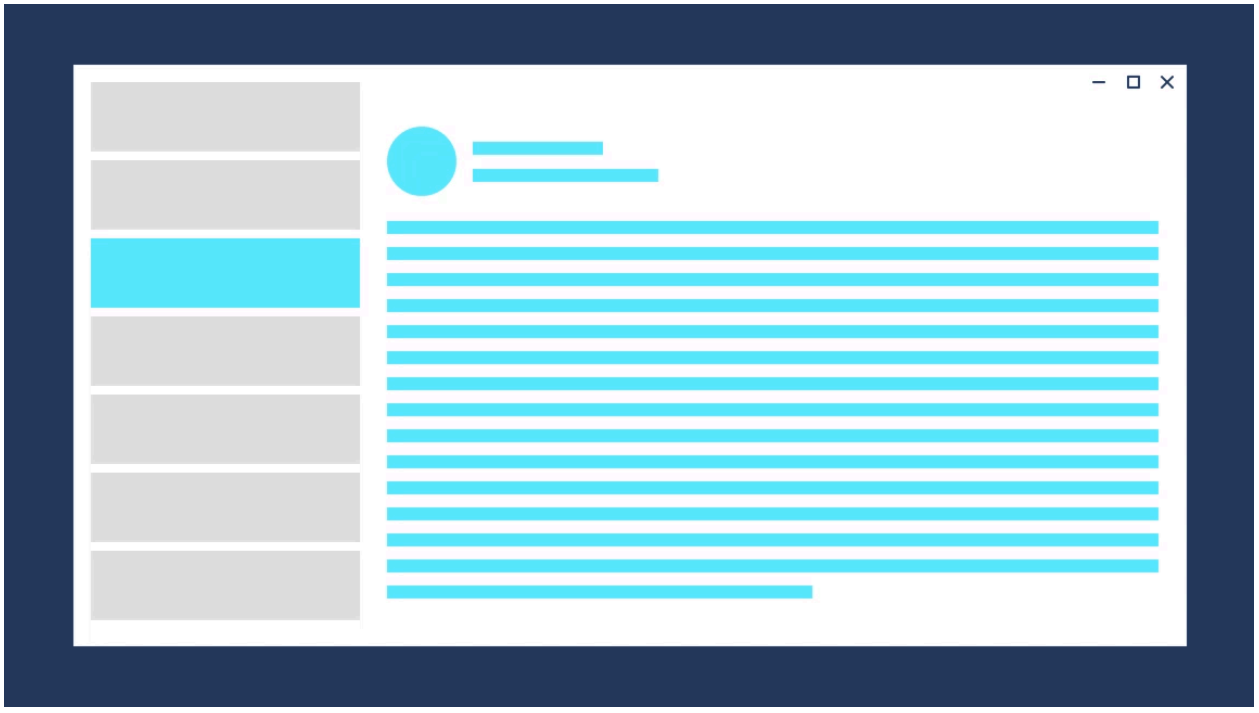
Article • 11/05/2024

Timing, easing, directionality, and gravity work together to form the foundation of Fluent motion. Each has to be considered in the context of the others, and applied appropriately in the context of your app.

Here are 3 ways to apply Fluent motion fundamentals in your app.

- **Implicit animation**
  Automatic tween and timing between values in a parameter change to achieve very simple Fluent motion using the standardized values.
- **Built-in animation**
  System components, such as common controls and shared motion, are "Fluent by default". Fundamentals have been applied in a manner consistent with their implied usage.
- **Custom animation following guidance recommendations**
  There may be times when the system does not yet provide an exact motion solution for your scenario. In those cases, use the baseline fundamental recommendations as a starting point for your experiences.

Transition example



Direction Forward Out:
Fade out: 150m; Easing: Default Accelerate **Direction Forward In:**
Slide up 150px: 300ms; Easing: Default Decelerate

Direction Backward Out:
Slide down 150px: 150ms; Easing: Default Accelerate **Direction Backward In:**
Fade in: 300ms; Easing: Default Decelerate

Object example

Direction Expand:
Grow: 300ms; Easing: Standard

Direction Contract:
Grow: 150ms; Easing: Default Accelerate

Examples

Open the WinUI 3 Gallery app and see Implicit Transitions in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

Implicit Animations

Implicit animations are a simple way to achieve Fluent motion by automatically interpolating between the old and new values during a parameter change.

You can implicitly animate changes to the following properties:

- UIElement
  - **Opacity**
  - **Rotation**
  - **Scale**
  - **Translation**

- Border, ContentPresenter, or Panel
  - **Background**

Each property that can have changes implicitly animated has a corresponding *transition* property. To animate the property, you assign a transition type to the corresponding *transition* property. This table shows the *transition* properties and the transition type to use for each one.

Expand table

Animated property	Transition property	Implicit transition type
UIElement.Opacity	OpacityTransition	ScalarTransition
UIElement.Rotation	RotationTransition	ScalarTransition
UIElement.Scale	ScaleTransition	Vector3Transition
UIElement.Translation	TranslationTransition	Vector3Transition
Border.Background	BackgroundTransition	BrushTransition
ContentPresenter.Background	BackgroundTransition	BrushTransition
Panel.Background	BackgroundTransition	BrushTransition

This example shows how to use the Opacity property and transition to make a button fade in when the control is enabled and fade out when it's disabled.

XAML

```
<Button x:Name="SubmitButton"
        Content="Submit"
        Opacity="{x:Bind OpaqueIfEnabled(SubmitButton.IsEnabled),
Mode=OneWay}">
    <Button.OpacityTransition>
        <ScalarTransition />
    </Button.OpacityTransition>
</Button>
```

C#

```
public double OpaqueIfEnabled(bool IsEnabled)
{
    return IsEnabled ? 1.0 : 0.2;
}
```

UWP and WinUI 2

> **Important**
>
> The information and examples in this article are optimized for apps that use the **Windows App SDK** and **WinUI 3**, but are generally applicable to UWP apps that use **WinUI 2**. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

- ✓ **UWP APIs:** Windows.UI.Xaml.Media.Animation Namespace, Windows.UI.Xaml.Controls namespace
- ✓ **WinUI 2 Apis:** Microsoft.UI.Xaml.Controls namespace
- ✓ Open the WinUI 2 Gallery app and see Implicit Transitions in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

Implicit animations require Windows 10, version 1809 (SDK 17763) or later.

Page transitions

Article • 05/17/2022

Page transitions navigate users between pages in an app, providing feedback as the relationship between pages. Page transitions help users understand if they are at the top of a navigation hierarchy, moving between sibling pages, or navigating deeper into the page hierarchy.

Two different animations are provided for navigation between pages in an app, *Page refresh* and *Drill*, and are represented by subclasses of **NavigationTransitionInfo**.

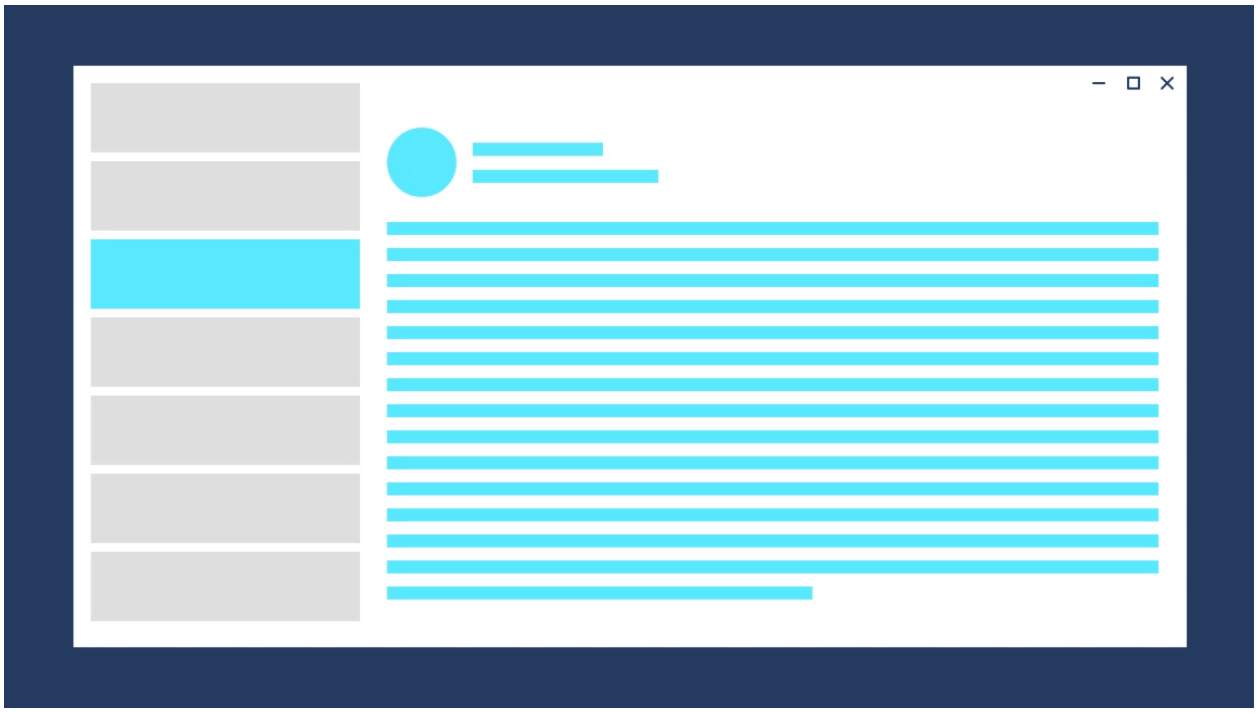
Examples

WinUI 2 Gallery	
	If you have the **WinUI 2 Gallery** app installed, click here to open the app and see Page Transitions in action. • Get the WinUI 2 Gallery app (Microsoft Store) • Get the source code (GitHub)

Page refresh

Page refresh is a combination of a slide up animation and a fade in animation for the incoming content. Use page refresh when the user is taken to the top of a navigational stack, such as navigating between tabs or left-nav items.

The desired feeling is that the user has started over.



The page refresh animation is represented by the EntranceNavigationTransitionInfoClass.

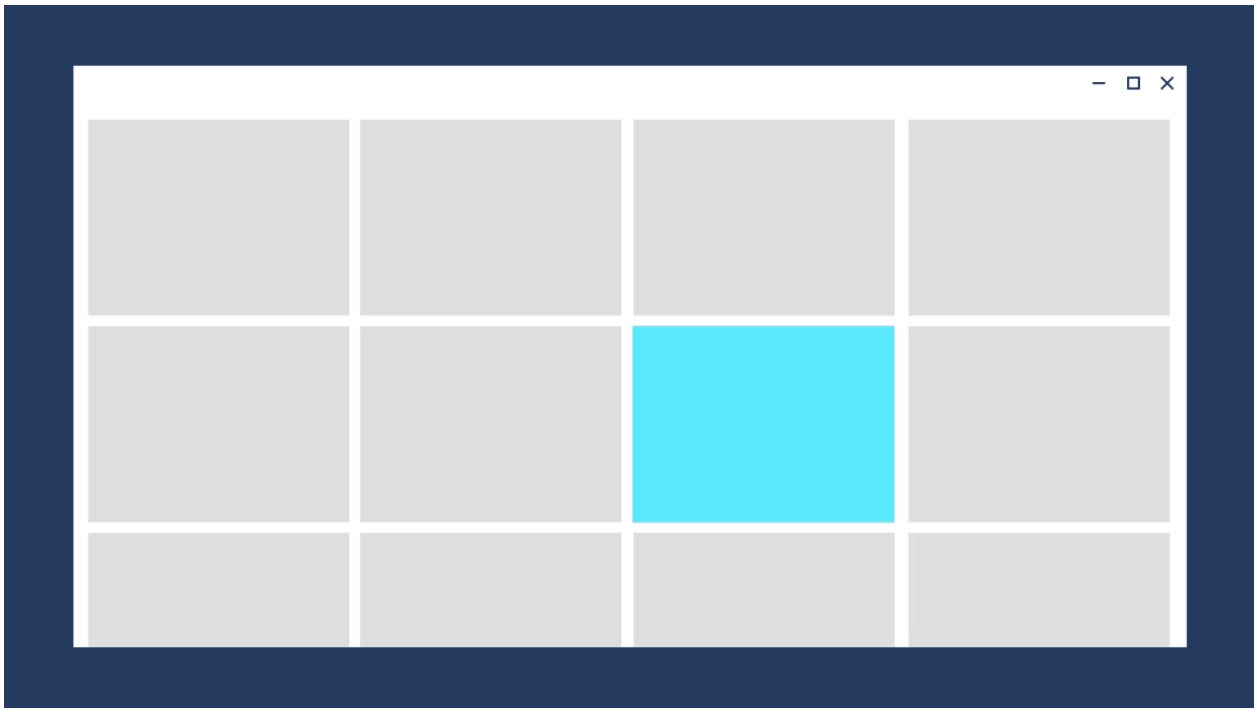
```C#
// Explicitly play the page refresh animation
myFrame.Navigate(typeof(Page2), null, new
EntranceNavigationTransitionInfo());
```

Note: A Frame automatically uses NavigationThemeTransition to animate navigation between two pages. By default, the animation is page refresh.

Drill

Use drill when users navigate deeper into an app, such as displaying more information after selecting an item.

The desired feeling is that the user has gone deeper into the app.



The drill animation is represented by the **DrillInNavigationTransitionInfo** class.

C#

```
// Play the drill in animation
myFrame.Navigate(typeof(Page2), null, new
DrillInNavigationTransitionInfo());
```

Horizontal slide

Use horizontal slide to show that sibling pages appear next to each other. The NavigationView control automatically uses this animation for top nav, but if you are building your own horizontal navigation experience, then you can implement horizontal slide with SlideNavigationTransitionInfo.

The desired feeling is that the user is navigating between pages that are next to each other.

C#

```
// Navigate to the right, ie. from LeftPage to RightPage
myFrame.Navigate(typeof(RightPage), null, new
SlideNavigationTransitionInfo() { Effect =
SlideNavigationTransitionEffect.FromRight } );

// Navigate to the left, ie. from RightPage to LeftPage
myFrame.Navigate(typeof(LeftPage), null, new SlideNavigationTransitionInfo()
{ Effect = SlideNavigationTransitionEffect.FromLeft } );
```

Suppress

To avoid playing any animation during navigation, use **SuppressNavigationTransitionInfo** in the place of other **NavigationTransitionInfo** subtypes.

```
C#
```

```
// Suppress the default animation
myFrame.Navigate(typeof(Page2), null, new
SuppressNavigationTransitionInfo());
```

Suppressing the animation is useful if you are building your own transition using Connected Animations or implicit show/hide animations.

Backwards navigation

You can use `Frame.GoBack(NavigationTransitionInfo)` to play a specific transition when navigating backwards.

This can be useful when you modify navigation behavior dynamically based on screen size; for example, in a responsive list/detail scenario.

Connected animation for Windows apps

Article • 05/17/2022

Connected animations let you create a dynamic and compelling navigation experience by animating the transition of an element between two different views. This helps the user maintain their context and provides continuity between the views.

In a connected animation, an element appears to "continue" between two views during a change in UI content, flying across the screen from its location in the source view to its destination in the new view. This emphasizes the common content between the views and creates a beautiful and dynamic effect as part of a transition.

> **Important APIs**: ConnectedAnimation class, ConnectedAnimationService class

Examples

WinUI 2 Gallery	
	If you have the **WinUI 2 Gallery** app installed, click here to open the app and see Connected Animation in action. • Get the WinUI 2 Gallery app (Microsoft Store) • Get the source code (GitHub)

In this short video, an app uses a connected animation to animate an item image as it "continues" to become part of the header of the next page. The effect helps maintain user context across the transition.

Connected animation and the Fluent Design System

The Fluent Design System helps you create modern, bold UI that incorporates light, depth, motion, material, and scale. Connected animation is a Fluent Design System component that adds motion to your app. To learn more, see the Fluent Design overview.

Why connected animation?

When navigating between pages, it's important for the user to understand what new content is being presented after the navigation and how it relates to their intent when navigating. Connected animations provide a powerful visual metaphor that emphasizes the relationship between two views by drawing the user's focus to the content shared between them. Additionally, connected animations add visual interest and polish to page navigation that can help differentiate the motion design of your app.

When to use connected animation

Connected animations are generally used when changing pages, though they can be applied to any experience where you are changing content in a UI and want the user to maintain context. You should consider using a connected animation instead of a drill in navigation transition whenever there is an image or other piece of UI shared between the source and destination views.

Configure connected animation

> **ⓘ Important**
>
> This feature requires that your app's Target version be Windows 10, version 1809 (**SDK 17763**) or later. The Configuration property is not available in earlier SDKs. You can target a Minimum version lower than SDK 17763 using adaptive code or conditional XAML. For more info, see **Version adaptive apps**.

Starting in Windows 10, version 1809, connected animations further embody Fluent design by providing animation configurations tailored specifically for forward and backwards page navigation.

You specify an animation configuration by setting the Configuration property on the ConnectedAnimation. (We'll show examples of this in the next section.)

This table describes the available configurations. For more information about the motion principles applied in these animations, see Directionality and gravity.

GravityConnectedAnimationConfiguration
This is the default configuration, and is recommended for forward navigation.
As the user navigates forward in the app (A to B), the connected element appears to physically "pull off the page". In doing so, the element appears to move forward in z-space and drops a bit as an effect of gravity taking hold. To overcome the effects of gravity, the element gains velocity and accelerates into its final position. The result is a "scale and dip" animation.

DirectConnectedAnimationConfiguration
As the user navigates backwards in the app (B to A), the animation is more direct. The connected element linearly translates from B to A using a decelerate cubic Bezier easing function. The backwards visual affordance returns the user to their previous state as fast as possible while still maintaining the context of the navigation flow.

BasicConnectedAnimationConfiguration
This is the default (and only) animation used in versions prior to Windows 10, version 1809 (SDK 17763).

ConnectedAnimationService configuration

The ConnectedAnimationService class has two properties that apply to the individual animations rather than the overall service.

- DefaultDuration
- DefaultEasingFunction

To achieve the various effects, some configurations ignore these properties on ConnectedAnimationService and use their own values instead, as described in this table.

Configuration	**Respects DefaultDuration?**	**Respects DefaultEasingFunction?**
Gravity	Yes	Yes* **The basic translation from A to B uses this easing function, but the "gravity dip" has its own easing function.*

Configuration	Respects DefaultDuration?	Respects DefaultEasingFunction?
Direct	No *Animates over 150ms.*	No *Uses the Decelerate easing function.*
Basic	Yes	Yes

How to implement connected animation

Setting up a connected animation involves two steps:

1. *Prepare* an animation object on the source page, which indicates to the system that the source element will participate in the connected animation.
2. *Start* the animation on the destination page, passing a reference to the destination element.

When navigating from the source page, call ConnectedAnimationService.GetForCurrentView to get an instance of ConnectedAnimationService. To prepare an animation, call PrepareToAnimate on this instance, and pass in a unique key and the UI element you want to use in the transition. The unique key lets you retrieve the animation later on the destination page.

C#

```
ConnectedAnimationService.GetForCurrentView()
    .PrepareToAnimate("forwardAnimation", SourceImage);
```

When the navigation occurs, start the animation in the destination page. To start the animation, call ConnectedAnimation.TryStart. You can retrieve the right animation instance by calling ConnectedAnimationService.GetAnimation with the unique key you provided when creating the animation.

C#

```
ConnectedAnimation animation =

ConnectedAnimationService.GetForCurrentView().GetAnimation("forwardAnimation
");
if (animation != null)
{
    animation.TryStart(DestinationImage);
}
```

Forward navigation

This example shows how to use ConnectedAnimationService to create a transition for forward navigation between two pages (Page_A to Page_B).

The recommended animation configuration for forward navigation is GravityConnectedAnimationConfiguration. This is the default, so you don't need to set the Configuration property unless you want to specify a different configuration.

Set up the animation in the source page.

XAML

```
<!-- Page_A.xaml -->

<Image x:Name="SourceImage"
       HorizontalAlignment="Left" VerticalAlignment="Top"
       Width="200" Height="200"
       Stretch="Fill"
       Source="Assets/StoreLogo.png"
       PointerPressed="SourceImage_PointerPressed"/>
```

C#

```
// Page_A.xaml.cs

private void SourceImage_PointerPressed(object sender,
PointerRoutedEventArgs e)
{
    // Navigate to detail page.
    // Suppress the default animation to avoid conflict with the connected
animation.
    Frame.Navigate(typeof(Page_B), null, new
SuppressNavigationTransitionInfo());
}

protected override void OnNavigatingFrom(NavigatingCancelEventArgs e)
{
    ConnectedAnimationService.GetForCurrentView()
        .PrepareToAnimate("forwardAnimation", SourceImage);
    // You don't need to explicitly set the Configuration property because
    // the recommended Gravity configuration is default.
    // For custom animation, use:
    // animation.Configuration = new BasicConnectedAnimationConfiguration();
}
```

Start the animation in the destination page.

XAML

```
<!-- Page_B.xaml -->

<Image x:Name="DestinationImage"
       Width="400" Height="400"
       Stretch="Fill"
       Source="Assets/StoreLogo.png" />
```

C#

```
// Page_B.xaml.cs

protected override void OnNavigatedTo(NavigationEventArgs e)
{
    base.OnNavigatedTo(e);

    ConnectedAnimation animation =

ConnectedAnimationService.GetForCurrentView().GetAnimation("forwardAnimation
");
    if (animation != null)
    {
        animation.TryStart(DestinationImage);
    }
}
```

Back navigation

For back navigation (Page_B to Page_A), you follow the same steps, but the source and destination pages are reversed.

When the user navigates back, they expect the app to be returned to the previous state as soon as possible. Therefore, the recommended configuration is DirectConnectedAnimationConfiguration. This animation is quicker, more direct, and uses the decelerate easing.

Set up the animation in the source page.

C#

```
// Page_B.xaml.cs

protected override void OnNavigatingFrom(NavigatingCancelEventArgs e)
{
    if (e.NavigationMode == NavigationMode.Back)
    {
        ConnectedAnimation animation =

ConnectedAnimationService.GetForCurrentView().PrepareToAnimate("backAnimatio
```

```
n", DestinationImage);

        // Use the recommended configuration for back animation.
        animation.Configuration = new
DirectConnectedAnimationConfiguration();
    }
}
```

Start the animation in the destination page.

C#

```
// Page_A.xaml.cs

protected override void OnNavigatedTo(NavigationEventArgs e)
{
    base.OnNavigatedTo(e);

    ConnectedAnimation animation =

ConnectedAnimationService.GetForCurrentView().GetAnimation("backAnimation");
    if (animation != null)
    {
        animation.TryStart(SourceImage);
    }
}
```

Between the time that the animation is set up and when it's started, the source element appears frozen above other UI in the app. This lets you perform any other transition animations simultaneously. For this reason, you shouldn't wait more than ~250 milliseconds in between the two steps because the presence of the source element may become distracting. If you prepare an animation and do not start it within three seconds, the system will dispose of the animation and any subsequent calls to TryStart will fail.

Connected animation in list and grid experiences

Often, you will want to create a connected animation from or to a list or grid control. You can use the two methods on ListView and GridView, PrepareConnectedAnimation and TryStartConnectedAnimationAsync, to simplify this process.

For example, say you have a **ListView** that contains an element with the name "PortraitEllipse" in its data template.

XAML

```
<ListView x:Name="ContactsListView" Loaded="ContactsListView_Loaded">
    <ListView.ItemTemplate>
        <DataTemplate x:DataType="vm:ContactsItem">
            <Grid>
                …
                <Ellipse x:Name="PortraitEllipse" … />
            </Grid>
        </DataTemplate>
    </ListView.ItemTemplate>
</ListView>
```

To prepare a connected animation with the ellipse corresponding to a given list item, call the PrepareConnectedAnimation method with a unique key, the item, and the name "PortraitEllipse".

C#

```
void PrepareAnimationWithItem(ContactsItem item)
{
     ContactsListView.PrepareConnectedAnimation("portrait", item,
"PortraitEllipse");
}
```

To start an animation with this element as the destination, such as when navigating back from a detail view, use TryStartConnectedAnimationAsync. If you have just loaded the data source for the ListView, TryStartConnectedAnimationAsync will wait to start the animation until the corresponding item container has been created.

C#

```
private async void ContactsListView_Loaded(object sender, RoutedEventArgs e)
{
    ContactsItem item = GetPersistedItem(); // Get persisted item
    if (item != null)
    {
        ContactsListView.ScrollIntoView(item);
        ConnectedAnimation animation =

ConnectedAnimationService.GetForCurrentView().GetAnimation("portrait");
        if (animation != null)
        {
            await ContactsListView.TryStartConnectedAnimationAsync(
                animation, item, "PortraitEllipse");
        }
    }
}
```

Coordinated animation

A *coordinated animation* is a special type of entrance animation where an element appears along with the connected animation target, animating in tandem with the connected animation element as it moves across the screen. Coordinated animations can add more visual interest to a transition and further draw the user's attention to the context that is shared between the source and destination views. In these images, the caption UI for the item is animating using a coordinated animation.

When a coordinated animation uses the gravity configuration, gravity is applied to both the connected animation element and the coordinated elements. The coordinated elements will "swoop" alongside the connected element so the elements stay truly coordinated.

Use the two-parameter overload of **TryStart** to add coordinated elements to a connected animation. This example demonstrates a coordinated animation of a Grid layout named "DescriptionRoot" that enters in tandem with a connected animation element named "CoverImage".

XAML

```
<!-- DestinationPage.xaml -->
<Grid>
    <Image x:Name="CoverImage" />
    <Grid x:Name="DescriptionRoot" />
</Grid>
```

C#

```
// DestinationPage.xaml.cs
void OnNavigatedTo(NavigationEventArgs e)
{
    var animationService = ConnectedAnimationService.GetForCurrentView();
    var animation = animationService.GetAnimation("coverImage");

    if (animation != null)
    {
        // Don’t need to capture the return value as we are not scheduling
any subsequent
        // animations
        animation.TryStart(CoverImage, new UIElement[] { DescriptionRoot });
     }
}
```

Do’s and don’ts

- Use a connected animation in page transitions where an element is shared between the source and destination pages.
- Use GravityConnectedAnimationConfiguration for forward navigation.
- Use DirectConnectedAnimationConfiguration for back navigation.
- Don't wait on network requests or other long-running asynchronous operations in between preparing and starting a connected animation. You may need to pre-load the necessary information to run the transition ahead of time, or use a low-resolution placeholder image while a high-resolution image loads in the destination view.
- Use SuppressNavigationTransitionInfo to prevent a transition animation in a **Frame** if you are using **ConnectedAnimationService**, since connected animations aren't meant to be used simultaneously with the default navigation transitions. See NavigationThemeTransition for more info on how to use navigation transitions.

Parallax

Article • 05/17/2022

Parallax is a visual effect where items closer to the viewer move faster than items in the background. Parallax creates a feeling of depth, perspective, and movement. In a UWP app, you can use the ParallaxView control to create a parallax effect.

> **WinUI APIs:** ParallaxView class, VerticalShift property, HorizontalShift property
>
> **Platform APIs**: ParallaxView class, VerticalShift property, HorizontalShift property

Examples

Expand table

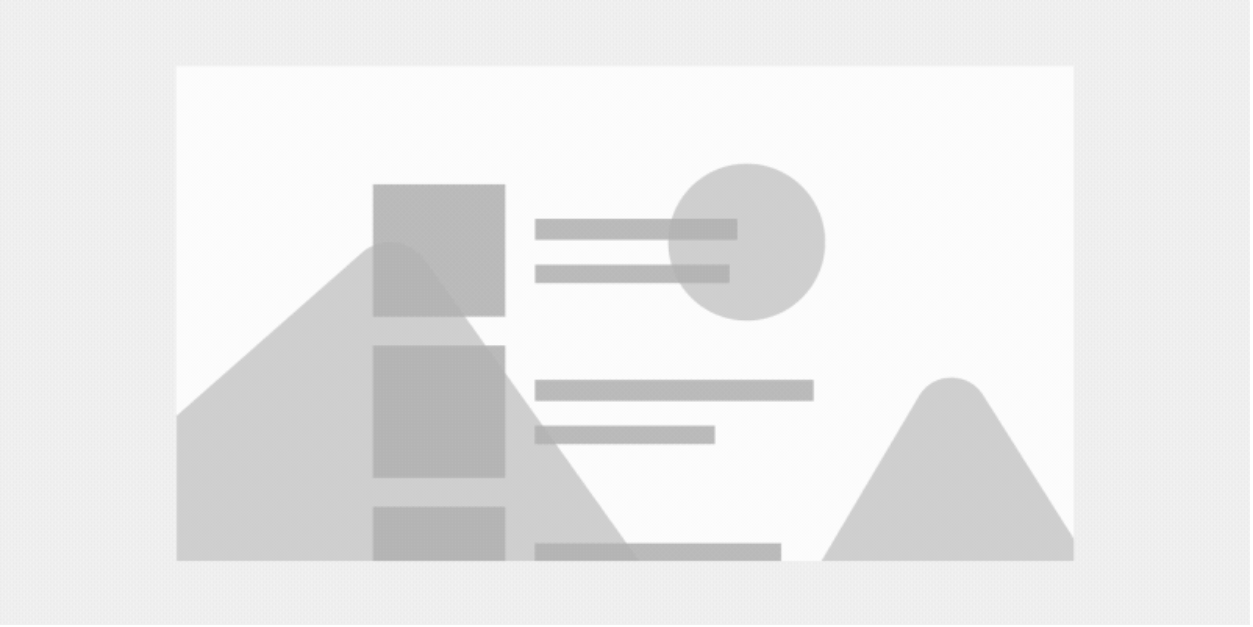
WinUI 2 Gallery	
	If you have the **WinUI 2 Gallery** app installed, click here to open the app and see the ParallaxView in action. • Get the WinUI 2 Gallery app (Microsoft Store) • Get the source code (GitHub)

Parallax and the Fluent Design System

The Fluent Design System helps you create modern, bold UI that incorporates light, depth, motion, material, and scale. Parallax is a Fluent Design System component that adds motion, depth, and scale to your app. To learn more, see the Fluent Design overview.

How it works in a user interface

In a UI, you can create a parallax effect by moving different objects at different rates when the UI scrolls or pans. To demonstrate, let's look at two layers of content, a list and a background image. The list is placed on top of the background image which already gives the illusion that the list might be closer to the viewer. Now, to achieve the parallax effect, we want the object closest to us to travel "faster" than the object that is farther away. As the user scrolls the interface, the list moves at a faster rate than the background image, which creates the illusion of depth.



Using the ParallaxView control to create a parallax effect

To create a parallax effect, you use the ParallaxView control. This control ties the scroll position of a foreground element, such as a list, to a background element, such as an image. As you scroll through the foreground element, it animates the background element to create a parallax effect.

To use the ParallaxView control, you provide a Source element, a background element, and set the VerticalShift (for vertical scrolling) and/or HorizontalShift (for horizontal scrolling) properties to a value greater than zero.

- The Source property takes a reference to the foreground element. For the parallax effect to occur, the foreground should be a ScrollViewer or an element that contains a ScrollViewer, such as a ListView or a RichTextBox.
- To set the background element, you add that element as a child of the ParallaxView control. The background element can be any UIElement, such as an Image or a panel that contains additional UI elements.

To create a parallax effect, the ParallaxView must be behind the foreground element. The Grid and Canvas panels let you layer items on top of each other, so they work well with the ParallaxView control.

This example creates a parallax effect for a list:

XAML

```
<Grid>
    <ParallaxView Source="{x:Bind ForegroundElement}" VerticalShift="50">

        <!-- Background element -->
        <Image x:Name="BackgroundImage" Source="Assets/turntable.png"
               Stretch="UniformToFill"/>
    </ParallaxView>

    <!-- Foreground element -->
    <ListView x:Name="ForegroundElement">
       <x:String>Item 1</x:String>
       <x:String>Item 2</x:String>
       <x:String>Item 3</x:String>
       <x:String>Item 4</x:String>
       <x:String>Item 5</x:String>
       <x:String>Item 6</x:String>
       <x:String>Item 7</x:String>
       <x:String>Item 8</x:String>
       <x:String>Item 9</x:String>
       <x:String>Item 10</x:String>
       <x:String>Item 11</x:String>
       <x:String>Item 13</x:String>
       <x:String>Item 14</x:String>
       <x:String>Item 15</x:String>
       <x:String>Item 16</x:String>
       <x:String>Item 17</x:String>
       <x:String>Item 18</x:String>
       <x:String>Item 19</x:String>
       <x:String>Item 20</x:String>
       <x:String>Item 21</x:String>
    </ListView>
</Grid>
```

The ParallaxView automatically adjusts the size of the image so it works for the parallax operation so you don't have to worry about the image scrolling out of view.

Customizing the parallax effect

The VerticalShift and HorizontalShift properties let you control degree of the parallax effect.

- The VerticalShift property specifies how far we want the background to vertically shift during the entire parallax operation. A value of 0 means the background doesn't move at all.
- The HorizontalShift property specifies how far we want the background to horizontally shift during the entire parallax operation. A value of 0 means the background doesn't move at all.

Larger values create a more dramatic effect.

For the complete list of ways to customize parallax, see the ParallaxView class.

Do's and don'ts

- Use parallax in lists with a background image
- Consider using parallax in ListViewItems when ListViewItems contain an image
- Don't use it everywhere, overuse can diminish its impact

Animations in XAML

Article • 01/04/2023

Animations can enhance your app by adding movement and interactivity. By using the animations from the Windows Runtime animation library, you can integrate the Windows look and feel into your app. This topic provides a summary of the animations and examples of typical scenarios where each is used.

> **Tip**
>
> The Windows Runtime controls for XAML include certain types of animations as built-in behaviors that come from an animation library. By using these controls in your app, you can get the animated look and feel without having to program it yourself.

Animations from the Windows Runtime animation library provide these benefits:

- Motions that align to the Guidelines for animations
- Fast, fluid transitions between UI states that inform but do not distract the user
- Visual behavior that indicates transitions within an app to the user

For example, when the user adds an item to a list, instead of the new item instantly appearing in the list, the new item animates into place. The other items in the list animate to their new positions over a short period of time, making room for the added item. The transition behavior here makes the control interaction more apparent to the user.

Windows 10, version 1607 introduces a new **ConnectedAnimationService** API for implementing animations where an element appears to animate between views during a navigation. This API has a different usage pattern from the other animation library API's. Usage of **ConnectedAnimationService** is covered in the reference page.

The animation library does not provide animations for every possible scenario. There are cases where you might wish to create a custom animation in XAML. For more info, see Storyboarded animations.

Additionally, for certain advanced scenarios like animating an item based on scroll position of a ScrollViewer, developers may wish to use Visual Layer interoperation to implement custom animations. See Visual Layer for more information.

Types of animations

The Windows Runtime animation system and the animation library serve the larger goal of enabling controls and other parts of UI to have an animated behavior. There are several distinct types of animations.

- *Theme transitions* are applied automatically when certain conditions change in the UI, involving controls or elements from the predefined Windows Runtime XAML UI types. These are termed *theme transitions* because the animations support the Windows look and feel, and define what all apps do for particular UI scenarios when they change from one interaction mode to another. The theme transitions are part of the animation library.
- *Theme animations* are animations to one or more properties of predefined Windows Runtime XAML UI types. Theme animations differ from theme transitions because theme animations target one specific element and exist in specific visual states within a control, whereas the theme transitions are assigned to properties of the control that exist outside of the visual states and influence the transitions between those states. Many of the Windows Runtime XAML controls include theme animations within storyboards that are part of their control template, with the animations triggered by visual states. So long as you're not modifying the templates, you'll have those built-in theme animations available for the controls in your UI. However, if you do replace templates, then you'll be removing the built-in control theme animations too. To get them back, you must define a storyboard that includes theme animations within the control's set of visual states. You can also run theme animations from storyboards that aren't within visual states and start them with the **Begin** method, but that's less common. Theme animations are part of the animation library.
- *Visual transitions* are applied when a control transitions from one of its defined visual states to another state. These are custom animations that you write, and are typically related to the custom template you write for a control and the visual state definitions within that template. The animation only runs during the time between states, and that's typically a short amount of time, a few seconds at most. For more info, see "VisualTransition" section of Storyboarded animations for visual states.
- *Storyboarded animations* animate the value of a Windows Runtime dependency property over time. Storyboards can be defined as part of a visual transition, or triggered at runtime by the application. For more info, see Storyboarded animations. For more info about dependency properties and where they exist, see Dependency properties overview.
- *Connected animations* provided by the new **ConnectedAnimationService** API allow developers to easily create an effect where an element appears to animate

between views during a navigation. This API is available starting in Windows 10, version 1607. See **ConnectedAnimationService** for more information.

Animations available in the library

The following animations are supplied in the animation library. Click on the name of an animation to learn more about their main usage scenarios, how to define them, and to see an example of the animation.

- Page transition: Animates page transitions in a **Frame**.
- Content and entrance transition: Animates one piece or set of content into or out of view.
- Fade in/out, and crossfade: Shows transient elements or controls, or refreshes a content area.
- Pointer up/down: Gives visual feedback of a tap or click on a tile.
- Reposition: Moves an element into a new position.
- Show/hide popup: Displays contextual UI on top of the view.
- Show/hide edge UI: Slides edge-based UI, including large UI such as a panel, into or out of view.
- List item changes: Adds or deletes an item from a list, or reordering of the items.
- Drag/drop: Gives visual feedback during a drag-and-drop operation.

Page transition

Use page transitions to animate navigation within an app. Since almost all apps use some kind of navigation, page transition animations are the most common type of theme animation used by apps. See **NavigationThemeTransition** for more information about the page transition APIs.

Content transition and entrance transition

Use content transition animations (**ContentThemeTransition**) to move a piece or a set of content into or out of the current view. For example, the content transition animations show content that was not ready to display when the page was first loaded, or when the content changes on a section of a page.

EntranceThemeTransition represents a motion that can apply to content when a page or large section of UI is first loaded. Thus the first appearance of content can offer different feedback than a change to content does. **EntranceThemeTransition** is equivalent to a **NavigationThemeTransition** with the default parameters, but may be used outside of a **Frame**.

Fade in/out, and crossfade

Use fade in and fade out animations to show or hide transient UI or controls. In XAML these are represented as **FadeInThemeAnimation** and **FadeOutThemeAnimation**. One example is in an app bar in which new controls can appear due to user interaction. Another example is a transient scroll bar or panning indicator that is faded out after no user input has been detected for some amount of time. Apps should also use the fade in animation when they transition from a placeholder item to the final item as content loads dynamically.

Use a crossfade animation to smooth the transition when an item's state is changing; for example, when the app refreshes the current contents of a view. The XAML animation library does not supply a dedicated crossfade animation (no equivalent for **crossFade**), but you can achieve the same result using **FadeInThemeAnimation** and **FadeOutThemeAnimation** with overlapped timing.

Pointer up/down

Use the **PointerUpThemeAnimation** and **PointerDownThemeAnimation** animations to give the user feedback for a successful tap or click on a tile. For example, when a user clicks or taps down on a tile, the pointer down animation is played. Once the click or tap has been released, the pointer up animation is played.

Reposition

Use the reposition animations (**RepositionThemeAnimation** or **RepositionThemeTransition**) to move an element into a new position. For example, moving the headers in an items control uses the reposition animation.

Show/hide popup

Use the **PopInThemeAnimation** and **PopOutThemeAnimation** when you show and hide a **Popup** or similar contextual UI on top of the current view. **PopupThemeTransition** is a theme transition that's useful feedback if you want to light dismiss a popup.

Show/hide edge UI

Use the **EdgeUIThemeTransition** animation to slide small, edge-based UI into and out of view. For example, use these animations when you show a custom app bar at the top or bottom of the screen or a UI surface for errors and warnings at the top of the screen.

Use the **PaneThemeTransition** animation to show and hide a pane or panel. This is for large edge-based UI such as a custom keyboard or a task pane.

List item changes

Use the **AddDeleteThemeTransition** animation to add animated behavior when you add or delete an item in an existing list. For add, the transition will first reposition existing items in the list to make space for the new items, and then add the new items. For delete, the transition removes items from a list and, if necessary, repositions the remaining list items once the deleted items have been removed.

There's also a separate **ReorderThemeTransition** that you apply if an item changes position in a list. This is animated differently than deleting an item and adding it in a new place with the associated delete/add animations.

Note that these animations are included in the default **ListView** and **GridView** templates so you do not need to manually add these animations if you are already using these controls.

Drag/drop

Use the drag animations (**DragItemThemeAnimation**, **DragOverThemeAnimation**) and drop animation (**DropTargetItemThemeAnimation**) to give visual feedback when the user drags or drops an item.

When active, the animations show the user that the list can be rearranged around a dropped item. It is helpful for users to know where the item will be placed in a list if it is dropped at the current location. The animations give visual feedback that an item being dragged can be dropped between two other items in the list and that those items will move out of the way.

Using animations with custom controls

The following table summarizes our recommendations for which animation you should use when you create a custom version of these Windows Runtime controls:

UI type	Recommended animation
Dialog box	FadeInThemeAnimation and FadeOutThemeAnimation

UI type	Recommended animation
Flyout	PopInThemeAnimation and PopOutThemeAnimation
Tooltip	FadeInThemeAnimation and FadeOutThemeAnimation
Context menu	PopInThemeAnimation and PopOutThemeAnimation
Command bar	EdgeUIThemeTransition
Task pane or edge-based panel	PaneThemeTransition
Contents of any UI container	ContentThemeTransition
For controls or if no other animation applies	FadeInThemeAnimation and FadeOutThemeAnimation

Transition animation examples

Ideally, your app uses animations to enhance the user interface or to make it more attractive without annoying your users. One way you can do this is to apply animated transitions to UI so that when something enters or leaves the screen or otherwise changes, the animation draws the attention of the user to the change. For example, your buttons may rapidly fade in and out of view rather than just appear and disappear. We created a number of APIs that can be used to create recommended or typical animation transitions that are consistent. The example here shows how to apply an animation to a button so that it swiftly slides into view.

XML

```
<Button Content="Transitioning Button">
     <Button.Transitions>
         <TransitionCollection>
             <EntranceThemeTransition/>
         </TransitionCollection>
     </Button.Transitions>
 </Button>
```

In this code, we add the EntranceThemeTransition object to the transition collection of the button. Now, when the button is first rendered, it swiftly slides into view rather than just appear. You can set a few properties on the animation object in order to adjust how

far it slides and from what direction, but it's really meant to be a simple API for a specific scenario, that is, to make an eye-catching entrance.

You can also define transition animation themes in the style resources of your app, allowing you to apply the effect uniformly. This example is equivalent to the previous one, only it is applied using a **Style**:

XML

```
<UserControl.Resources>
     <Style x:Key="DefaultButtonStyle" TargetType="Button">
         <Setter Property="Transitions">
             <Setter.Value>
                 <TransitionCollection>
                     <EntranceThemeTransition/>
                 </TransitionCollection>
             </Setter.Value>
         </Setter>
    </Style>
</UserControl.Resources>

<StackPanel x:Name="LayoutRoot">
    <Button Style="{StaticResource DefaultButtonStyle}"
Content="Transitioning Button"/>
</StackPanel>
```

The previous examples apply a theme transition to an individual control, however, theme transitions are even more interesting when you apply them to a container of objects. When you do this, all the child objects of the container take part in the transition. In the following example, an **EntranceThemeTransition** is applied to a **Grid** of rectangles.

XML

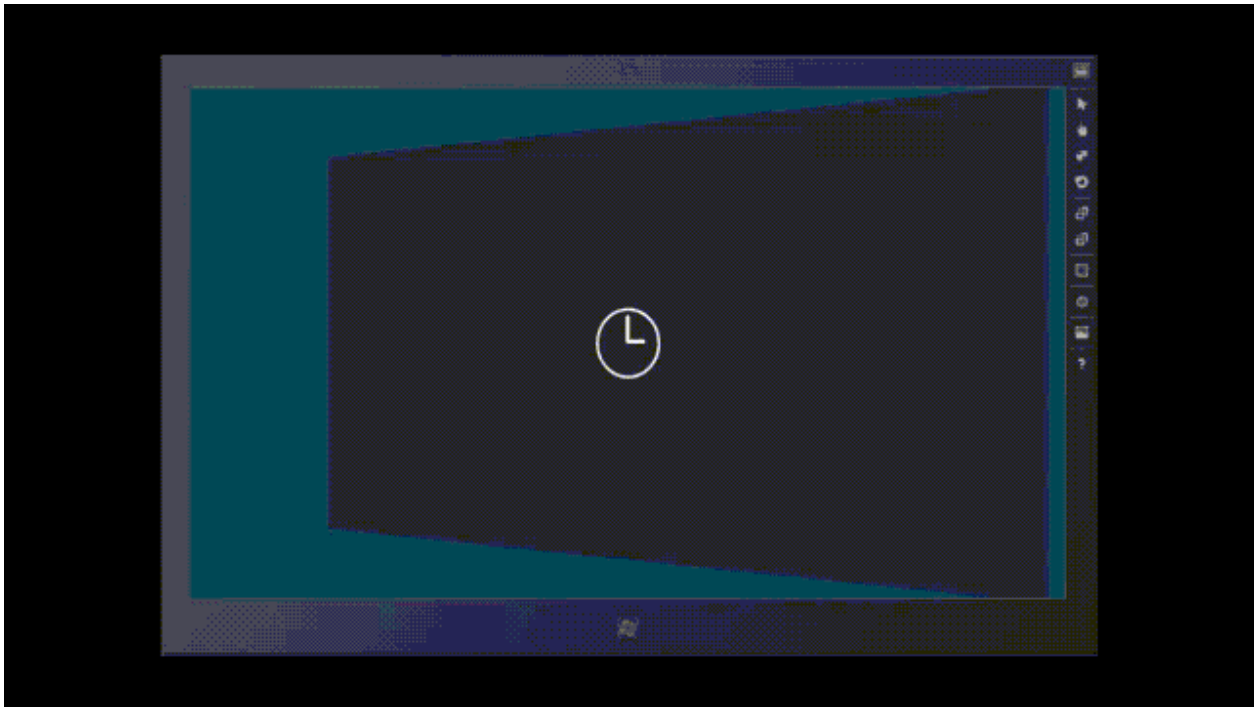
```
<!-- If you set an EntranceThemeTransition animation on a panel, the
     children of the panel will automatically offset when they animate
     into view to create a visually appealing entrance. -->
<ItemsControl Grid.Row="1" x:Name="rectangleItems">
    <ItemsControl.ItemContainerTransitions>
        <TransitionCollection>
            <EntranceThemeTransition/>
        </TransitionCollection>
    </ItemsControl.ItemContainerTransitions>
    <ItemsControl.ItemsPanel>
        <ItemsPanelTemplate>
            <WrapGrid Height="400"/>
        </ItemsPanelTemplate>
    </ItemsControl.ItemsPanel>

    <!-- The sequence children appear depends on their order in
```

```
            the panel's children, not necessarily on where they render
            on the screen. Be sure to arrange your child elements in
            the order you want them to transition into view. -->
        <ItemsControl.Items>
            <Rectangle Fill="Red" Width="100" Height="100" Margin="10"/>
            <Rectangle Fill="Red" Width="100" Height="100" Margin="10"/>
            <Rectangle Fill="Red" Width="100" Height="100" Margin="10"/>
            <Rectangle Fill="Red" Width="100" Height="100" Margin="10"/>
            <Rectangle Fill="Red" Width="100" Height="100" Margin="10"/>
            <Rectangle Fill="Red" Width="100" Height="100" Margin="10"/>
            <Rectangle Fill="Red" Width="100" Height="100" Margin="10"/>
            <Rectangle Fill="Red" Width="100" Height="100" Margin="10"/>
            <Rectangle Fill="Red" Width="100" Height="100" Margin="10"/>
        </ItemsControl.Items>
    </ItemsControl>
```

The child rectangles of the **Grid** transition into view one after the other in a visually pleasing way rather than all at once as would be the case if you applied this animation to the rectangles individually.

Here's a demonstration of this animation:



Child objects of a container can also re-flow when one or more of those children change position. In the following example, we apply a **RepositionThemeTransition** to a grid of rectangles. When you remove one of the rectangles, all the other rectangles re-flow into their new position.

XML

```
<Button Content="Remove Rectangle" Click="RemoveButton_Click"/>
```

```
<ItemsControl Grid.Row="1" x:Name="rectangleItems">
    <ItemsControl.ItemContainerTransitions>
        <TransitionCollection>

            <!-- Without this, there would be no animation when items
                 are removed. -->
            <RepositionThemeTransition/>
        </TransitionCollection>
    </ItemsControl.ItemContainerTransitions>
    <ItemsControl.ItemsPanel>
        <ItemsPanelTemplate>
            <WrapGrid Height="400"/>
        </ItemsPanelTemplate>
    </ItemsControl.ItemsPanel>

    <!-- All these rectangles are just to demonstrate how the items
         in the grid re-flow into position when one of the child items
         are removed. -->
    <ItemsControl.Items>
        <Rectangle Fill="Red" Width="100" Height="100" Margin="10"/>
        <Rectangle Fill="Red" Width="100" Height="100" Margin="10"/>
        <Rectangle Fill="Red" Width="100" Height="100" Margin="10"/>
        <Rectangle Fill="Red" Width="100" Height="100" Margin="10"/>
        <Rectangle Fill="Red" Width="100" Height="100" Margin="10"/>
        <Rectangle Fill="Red" Width="100" Height="100" Margin="10"/>
        <Rectangle Fill="Red" Width="100" Height="100" Margin="10"/>
        <Rectangle Fill="Red" Width="100" Height="100" Margin="10"/>
        <Rectangle Fill="Red" Width="100" Height="100" Margin="10"/>
    </ItemsControl.Items>
</ItemsControl>
```

C#

```
private void RemoveButton_Click(object sender, RoutedEventArgs e)
{
    if (rectangleItems.Items.Count > 0)
    {
        rectangleItems.Items.RemoveAt(0);
    }
}
```

C++

```
// .h
private:
void RemoveButton_Click(Platform::Object^ sender,
Windows::UI::Xaml::RoutedEventArgs^ e);

//.cpp
void BlankPage::RemoveButton_Click(Platform::Object^ sender,
Windows::UI::Xaml::RoutedEventArgs^ e)
{
```

```
    if (rectangleItems->Items->Size > 0)
    {
        rectangleItems->Items->RemoveAt(0);
    }
}
```

You can apply multiple transition animations to a single object or object container. For example, if you want the list of rectangles to animate into view and also animate when they change position, you can apply the RepositionThemeTransition and EntranceThemeTransition like this:

XML

```
...
<ItemsControl.ItemContainerTransitions>
    <TransitionCollection>
        <EntranceThemeTransition/>
        <RepositionThemeTransition/>
    </TransitionCollection>
</ItemsControl.ItemContainerTransitions>
...
```

There are several transition effects to create animations on your UI elements as they are added, removed, reordered, and so on. The names of these APIs all contain "ThemeTransition":

API	Description
NavigationThemeTransition	Provides a Windows personality animation for page navigation in a Frame.
AddDeleteThemeTransition	Provides the animated transition behavior for when controls add or delete children or content. Typically the control is an item container.
ContentThemeTransition	Provides the animated transition behavior for when the content of a control is changing. You can apply this in addition to AddDeleteThemeTransition.
EdgeUIThemeTransition	Provides the animated transition behavior for a (small) edge UI transition.
EntranceThemeTransition	Provides the animated transition behavior for when controls first appear.
PaneThemeTransition	Provides the animated transition behavior for a panel (large edge UI) UI transition.

API	Description
PopupThemeTransition	Provides the animated transition behavior that applies to pop-in components of controls (for example, tooltip-like UI on an object) as they appear.
ReorderThemeTransition	Provides the animated transition behavior for when list-view controls items change order. Typically this happens as a result of a drag-drop operation. Different controls and themes can have varying characteristics for the animations.
RepositionThemeTransition	Provides the animated transition behavior for when controls change position.

Theme animation examples

Transition animations are simple to apply. But you may want to have a bit more control over the timing and order of your animation effects. You can use theme animations to enable more control while still using a consistent theme for how your animation behaves. Theme animations also require less markup than custom animations. Here, we use the FadeOutThemeAnimation to make a rectangle fade out of view.

XML

```
<StackPanel>
    <StackPanel.Resources>
        <Storyboard x:Name="myStoryboard">
            <FadeOutThemeAnimation TargetName="myRectangle" />
        </Storyboard>
    </StackPanel.Resources>
    <Rectangle PointerPressed="Rectangle_Tapped" x:Name="myRectangle"
               Fill="Blue" Width="200" Height="300"/>
</StackPanel>
```

C#

```
// When the user taps the rectangle, the animation begins.
private void Rectangle_Tapped(object sender, PointerRoutedEventArgs e)
{
    myStoryboard.Begin();
}
```

VB

```
' When the user taps the rectangle, the animation begins.
Private Sub Rectangle_Tapped(sender As Object, e As PointerRoutedEventArgs)
    myStoryboard.Begin()
End Sub
```

C++

```
//.h
void Rectangle_Tapped(Platform::Object^ sender,
Windows::UI::Xaml::Input::PointerRoutedEventArgs^ e);

//.cpp
void BlankPage::Rectangle_Tapped(Object^ sender, PointerRoutedEventArgs^ e)
{
    myStoryboard->Begin();
}
```

Unlike transition animations, a theme animation doesn't have a built-in trigger (the transition) that runs it automatically. You must use a **Storyboard** to contain a theme animation when you define it in XAML. You can also change the default behavior of the animation. For example, you can slow down the fade-out by increasing the **Duration** time value on the **FadeOutThemeAnimation**.

Note For purposes of showing basic animation techniques, we're using app code to start the animation by calling methods of **Storyboard**. You can control how the **Storyboard** animations run using the **Begin**, **Stop**, **Pause**, and **Resume** **Storyboard** methods. However, that's not typically how you include library animations in apps. Rather, you usually integrate the library animations into the XAML styles and templates applied to controls or elements. Learning about templates and visual states is a little more involved. But we do cover how you'd use library animations in visual states as part of the Storyboarded animations for visual states topic.

You can apply several other theme animations to your UI elements to create animation effects. The names of these API all contain "ThemeAnimation":

API	Description
DragItemThemeAnimation	Represents the preconfigured animation that applies to item elements being dragged.
DragOverThemeAnimation	Represents the preconfigured animation that applies to the elements underneath an element being dragged.

API	Description
DropTargetItemThemeAnimation	The preconfigured animation that applies to potential drop target elements.
FadeInThemeAnimation	The preconfigured opacity animation that applies to controls when they first appear.
FadeOutThemeAnimation	The preconfigured opacity animation that applies to controls when they are removed from UI or hidden.
PointerDownThemeAnimation	The preconfigured animation for user action that taps or clicks an item or element.
PointerUpThemeAnimation	The preconfigured animation for user action that runs after a user taps down on an item or element and the action is released.
PopInThemeAnimation	The preconfigured animation that applies to pop-in components of controls as they appear. This animation combines opacity and translation.
PopOutThemeAnimation	The preconfigured animation that applies to pop-in components of controls as they are closed or removed. This animation combines opacity and translation.
RepositionThemeAnimation	The preconfigured animation for an object as it is repositioned.
SplitCloseThemeAnimation	The preconfigured animation that conceals a target UI using an animation in the style of a ComboBox opening and closing.
SplitOpenThemeAnimation	The preconfigured animation that reveals a target UI using an animation in the style of a ComboBox opening and closing.
DrillInThemeAnimation	Represents a preconfigured animation that runs when a user navigates forward in a logical hierarchy, like from a list page to a detail page.
DrillOutThemeAnimation	Represents a preconfigured animation that runs when a user navigates backward in a logical hierarchy, like from a detail page to a list page.

Create your own animations

When theme animations are not enough for your needs, you can create your own animations. You animate objects by animating one or more of their property values. For example, you can animate the width of a rectangle, the angle of a **RotateTransform**, or the color value of a button. We term this type of custom animation a storyboarded animation, to distinguish it from the library animations that the Windows Runtime already provides as a preconfigured animation type. For storyboarded animations, you use an animation that can change values of a particular type (for example **DoubleAnimation** to animate a **Double**) and put that animation within a **Storyboard** to control it.

In order to be animated, the property you are animating must be a *dependency property*. For more info about dependency properties, see Dependency properties overview. For more info on creating custom storyboarded animations, including how to target and control them, see Storyboarded animations.

The biggest area of app UI definition in XAML where you'll define custom storyboarded animations is if you are defining visual states for controls in XAML. You'll be doing this either because you are creating a new control class, or because you are re-templating an existing control that has visual states in its control template. For more info, see Storyboarded animations for visual states.

Animating XAML elements with composition animations

Article • 05/17/2022

This article introduces new properties that let you animate a XAML UIElement with the performance of composition animations and the ease of setting XAML properties.

Prior to Windows 10, version 1809, you had 2 choices to build animations in your UWP apps:

- use XAML constructs like Storyboarded animations, or the **ThemeTransition* and **ThemeAnimation* classes in the Windows.UI.Xaml.Media.Animation namespace.
- use composition animations as described in Using the Visual Layer with XAML.

Using the visual layer provides better performance than using the XAML constructs. But using ElementCompositionPreview to get the element's underlying composition Visual object, and then animating the Visual with composition animations, is more complex to use.

Starting in Windows 10, version 1809, you can animate properties on a UIElement directly using composition animations without the requirement to get the underlying composition Visual.

> **Note**
>
> To use these properties on UIElement, your UWP project target version must be 1809 or later. For more info about configuring your project version, see Version adaptive apps.

Examples

Expand table

WinUI 2 Gallery	
	If you have the **WinUI 2 Gallery** app installed, click here to open the app and see Animation interop in action. • Get the WinUI 2 Gallery app (Microsoft Store) • Get the source code (GitHub)

New rendering properties replace old rendering properties

This table shows the properties you can use to modify the rendering of a UIElement, that can also be animated with a CompositionAnimation.

Expand table

Property	Type	Description
Opacity	Double	The degree of the object's opacity
Translation	Vector3	Shift the X/Y/Z position of the element
TransformMatrix	Matrix4x4	The transform matrix to apply to the element
Scale	Vector3	Scale the element, centered on the CenterPoint
Rotation	Float	Rotate the element around the RotationAxis and CenterPoint
RotationAxis	Vector3	The axis of rotation
CenterPoint	Vector3	The center point of scale and rotation

The TransformMatrix property value is combined with the Scale, Rotation, and Translation properties in the following order: TransformMatrix, Scale, Rotation, Translation.

These properties don't affect the element's layout, so modifying these properties does not cause a new Measure/Arrange pass.

These properties have the same purpose and behavior as the like-named properties on the composition Visual class (except for Translation, which isn't on Visual).

Example: Setting the Scale property

This example shows how to set the Scale property on a Button.

XAML

```
<Button Scale="2,2,1" Content="I am a large button" />
```

C#

```
var button = new Button();
button.Content = "I am a large button";
```

```
button.Scale = new Vector3(2.0f,2.0f,1.0f);
```

Mutual exclusivity between new and old properties

> **Note**
>
> The **Opacity** property does not enforce the mutual exclusivity described in this section. You use the same Opacity property whether you use XAML or composition animations.

The properties that can be animated with a CompositionAnimation are replacements for several existing UIElement properties:

- RenderTransform
- RenderTransformOrigin
- Projection
- Transform3D

When you set (or animate) any of the new properties, you cannot use the old properties. Conversely, if you set (or animate) any of the old properties, you cannot use the new properties.

You also cannot use the new properties if you use ElementCompositionPreview to get and manage the Visual yourself using these methods:

- ElementCompositionPreview.GetElementVisual
- ElementCompositionPreview.SetIsTranslationEnabled

> **Important**
>
> Attempting to mix the use of the two sets of properties will cause the API call to fail and produce an error message.

It's possible to switch from one set of properties by clearing them, though for simplicity it's not recommended. If the property is backed by a DependencyProperty (for example, UIElement.Projection is backed by UIElement.ProjectionProperty), then call ClearValue to restore it to its "unused" state. Otherwise (for example, the Scale property), set the property to its default value.

Animating UIElement properties with CompositionAnimation

You can animate the rendering properties listed in the table with a CompositionAnimation. These properties can also be referenced by an ExpressionAnimation.

Use the StartAnimation and StopAnimation methods on UIElement to animate the UIElement properties.

Example: Animating the Scale property with a Vector3KeyFrameAnimation

This example shows how to animate the scale of a Button.

C#

```
var compositor = Window.Current.Compositor;
var animation = compositor.CreateVector3KeyFrameAnimation();

animation.InsertKeyFrame(1.0f, new Vector3(2.0f,2.0f,1.0f));
animation.Duration = TimeSpan.FromSeconds(1);
animation.Target = "Scale";

button.StartAnimation(animation);
```

Example: Animating the Scale property with an ExpressionAnimation

A page has two buttons. The second button animates to be twice as large (via scale) as the first button.

XAML

```
<Button x:Name="sourceButton" Content="Source"/>
<Button x:Name="destinationButton" Content="Destination"/>
```

C#

```
var compositor = Window.Current.Compositor;
var animation =
compositor.CreateExpressionAnimation("sourceButton.Scale*2");
animation.SetExpressionReferenceParameter("sourceButton", sourceButton);
```

```
animation.Target = "Scale";
destinationButton.StartAnimation(animation);
```

Storyboarded animations

Article • 05/24/2022

Storyboarded animations are not just animations in the visual sense. A storyboarded animation is a way to change the value of a dependency property as a function of time. One of the main reasons you might need a storyboarded animation that's not from the animation library is to define the visual state for a control, as part of a control template or page definition.

Differences with Silverlight and WPF

If you are familiar with Microsoft Silverlight or Windows Presentation Foundation (WPF), read this section; otherwise, you can skip it.

In general, creating storyboarded animations in a Windows Runtime app is like Silverlight or WPF. But there are a number of important differences:

- Storyboarded animations are not the only way to visually animate a UI, nor are they necessarily the easiest way for app developers to do so. Rather than using storyboarded animations it's often a better design practice to use theme animations and transition animations. These can quickly create recommended UI animations without getting into the intricacies of animation property targeting. For more info see Animations overview.
- In the Windows Runtime, many XAML controls include theme animations and transition animations as part of their built-in behavior. For the most part, WPF and Silverlight controls didn't have a default animation behavior.
- Not all custom animations you create can run by default in a Windows Runtime app, if the animation system determines that the animation might cause bad performance in your UI. Animations where the system determines there could be a performance impact are called *dependent animations*. It's dependent because the clocking of your animation is directly working against the UI thread, which is also where active user input and other updates are trying to apply the runtime changes to UI. A dependent animation that's consuming extensive system resources on the UI thread can make the app appear unresponsive in certain situations. If your animation causes a layout change or otherwise has the potential to impact performance on the UI thread, you often need to explicitly enable the animation to see it run. That's what the **EnableDependentAnimation** property on specific animation classes is for. See Dependent and independent animations for more info.
- Custom easing functions are not currently supported in the Windows Runtime.

Defining storyboarded animations

A storyboarded animation is a way to change the value of a dependency property as a function of time. The property you are animating is not always a property that directly affects the UI of your app. But since XAML is about defining UI for an app, usually it is a UI-related property you are animating. For example, you can animate the angle of a **RotateTransform**, or the color value of a button's background.

One of the main reasons you might be defining a storyboarded animation is if you are a control author or are re-templating a control, and you are defining visual states. For more info, see Storyboarded animations for visual states.

Whether you are defining visual states or a custom animation for an app, the concepts and APIs for storyboarded animations that are described in this topic mostly apply to either.

In order to be animated, the property you are targeting with a storyboarded animation must be a *dependency property*. A dependency property is a key feature of the Windows Runtime XAML implementation. The writeable properties of most common UI elements are typically implemented as dependency properties, so that you can animate them, apply data-bound values, or apply a **Style** and target the property with a **Setter**. For more info about how dependency properties work, see Dependency properties overview.

Most of the time, you define a storyboarded animation by writing XAML. If you use a tool such as Microsoft Visual Studio, it will produce the XAML for you. It's possible to define a storyboarded animation using code too, but that's less common.

Let's look at a simple example. In this XAML example, the **Opacity** property is animated on a particular **Rectangle** object.

XAML

```
<Page ...>
  <Page.Resources>
    <!-- Storyboard resource: Animates a rectangle's opacity. -->
    <Storyboard x:Name="myStoryboard">
      <DoubleAnimation
        Storyboard.TargetName="MyAnimatedRectangle"
        Storyboard.TargetProperty="Opacity"
        From="1.0" To="0.0" Duration="0:0:1"/>
    </Storyboard>
  </Page.Resources>

  <!--Page root element, UI definition-->
  <Grid>
```

```
    <Rectangle x:Name="MyAnimatedRectangle"
      Width="300" Height="200" Fill="Blue"/>
  </Grid>
</Page>
```

Identifying the object to animate

In the previous example, the storyboard was animating the **Opacity** property of a **Rectangle**. You don't declare the animations on the object itself. Instead, you do this within the animation definition of a storyboard. Storyboards are usually defined in XAML that's not in the immediate vicinity of the XAML UI definition of the object to animate. Instead, they're usually set up as a XAML resource.

To connect an animation to a target, you reference the target by its identifying programming name. You should always apply the x:Name attribute in the XAML UI definition to name the object that you want to animate. You then target the object to animate by setting **Storyboard.TargetName** within the animation definition. For the value of **Storyboard.TargetName**, you use the name string of the target object, which is what you set earlier and elsewhere with x:Name attribute.

Targeting the dependency property to animate

You set a value for **Storyboard.TargetProperty** in the animation. This determines which specific property of the targeted object is animated.

Sometimes you need to target a property that's not an immediate property of the target object, but that is nested more deeply in an object-property relationship. You often need to do this in order to drill down into a set of contributing object and property values until you can reference a property type that can be animated (**Double**, **Point**, **Color**). This concept is called *indirect targeting*, and the syntax for targeting a property in this way is known as a *property path*.

Here's an example. One common scenario for a storyboarded animation is to change the color of a part of an app UI or control in order to represent that the control is in a particular state. Say you want to animate the **Foreground** of a **TextBlock**, so that it turns from red to green. You'd expect that a **ColorAnimation** is involved, and that's correct. However, none of the properties on UI elements that affect the object's color are actually of type **Color**. Instead, they're of type **Brush**. So what you actually need to target for animation is the **Color** property of the **SolidColorBrush** class, which is a **Brush**-derived type that's typically used for these color-related UI properties. And here's what that looks like in terms of forming a property path for your animation's property targeting:

XAML

```
<Storyboard x:Name="myStoryboard">
  <ColorAnimation
    Storyboard.TargetName="tb1"
    Storyboard.TargetProperty="(TextBlock.Foreground).
(SolidColorBrush.Color)"
    From="Red" To="Green"/>
</Storyboard>
```

Here's how to think of this syntax in terms of its parts:

- Each set of () parentheses encloses a property name.
- Within the property name, there's a dot, and that dot separates a type name and a property name, so that the property you're identifying is unambiguous.
- The dot in the middle, the one that's not inside parentheses, is a step. This is interpreted by the syntax to mean, take the value of the first property (which is an object), step into its object model, and target a specific sub-property of the first property's value.

Here's a list of animation targeting scenarios where you'll probably be using indirect property targeting, and some property path strings that approximates the syntax you'll use:

- Animating the **X** value of a **TranslateTransform**, as applied to a **RenderTransform**: `(UIElement.RenderTransform).(TranslateTransform.X)`
- Animating a **Color** within a **GradientStop** of a **LinearGradientBrush**, as applied to a **Fill**: `(Shape.Fill).(GradientBrush.GradientStops)[0].(GradientStop.Color)`
- Animating the **X** value of a **TranslateTransform**, which is 1 of 4 transforms in a **TransformGroup**, as applied to a **RenderTransform**: `(UIElement.RenderTransform).(TransformGroup.Children)[3].(TranslateTransform.X)`

You'll notice some of these examples use square brackets around numbers. This is an indexer. It indicates that the property name preceding it has a collection as value, and that you want an item (as identified by a zero-based index) from within that collection.

You can also animate XAML attached properties. Always enclose the full attached property name in parentheses, for example `(Canvas.Left)`. For more info, see Animating XAML attached properties.

For more info on how to use a property path for indirect targeting of the property to animate, see Property-path syntax or **Storyboard.TargetProperty attached property**.

Animation types

The Windows Runtime animation system has three specific types that storyboarded animations can apply to:

- **Double**, can be animated with any **DoubleAnimation**
- **Point**, can be animated with any **PointAnimation**
- **Color**, can be animated with any **ColorAnimation**

There's also a generalized **Object** animation type for object reference values, which we'll discuss later.

Specifying the animated values

So far we've shown you how to target the object and the property to animate, but haven't yet described what the animation does to the property value when it runs.

The animation types we've described are sometimes referred to as **From/To/By** animations. This means that the animation is changing the value of a property, over time, using one or more of these inputs that come from the animation definition:

- The value starts at the **From** value. If you don't specify a **From** value, the starting value is whatever value the animated property has at the time before the animation runs. This might be a default value, a value from a style or template, or a value specifically applied by a XAML UI definition or app code.
- At the end of the animation, the value is the **To** value.
- Or, to specify an ending value relative to the starting value, set the **By** property. You'd set this instead of the **To** property.
- If you don't specify a **To** value or a **By** value, the ending value is whatever value the animated property has at the time before the animation runs. In this case you'd better have a **From** value because otherwise the animation won't change the value at all; its starting and ending values are both the same.
- An animation typically has at least one of **From**, **By** or **To** but never all three.

Let's revisit the earlier XAML example and look again at the **From** and **To** values, and the **Duration**. The example is animating the **Opacity** property, and the property type of **Opacity** is **Double**. So the animation to use here is **DoubleAnimation**.

`From="1.0" To="0.0"` specifies that when the animation runs, the **Opacity** property starts at a value of 1 and animates to 0. In other words, in terms of what these **Double** values mean to the **Opacity** property, this animation will cause the object to start opaque and then fade to transparent.

```
XAML
```

```
...
<Storyboard x:Name="myStoryboard">
  <DoubleAnimation
    Storyboard.TargetName="MyAnimatedRectangle"
    Storyboard.TargetProperty="Opacity"
    From="1.0" To="0.0" Duration="0:0:1"/>
</Storyboard>
...
```

`Duration="0:0:1"` specifies how long the animation lasts, that is, how fast the rectangle fades. A **Duration** property is specified in the form of *hours*:*minutes*:*seconds*. The time duration in this example is one second.

For more info about **Duration** values and the XAML syntax, see **Duration**.

> **Note**
>
> For the example we showed, if you were sure that the starting state of the object being animated has **Opacity** always equal to 1, either through the default or an explicit set, you could omit the **From** value, the animation would use the implicit starting value, and the result would be the same.

From/To/By are nullable

We mentioned previously that you can omit **From**, **To** or **By** and thus use current non-animated values as substitutes for a missing value. **From**, **To**, or **By** properties of an animation aren't of the type you might guess. For example the type of the **DoubleAnimation.To** property isn't **Double**. Instead, it's a **Nullable** for **Double**. And its default value is **null**, not 0. That **null** value is how the animation system distinguishes that you haven't specifically set a value for a **From**, **To**, or **By** property. Visual C++ component extensions (C++/CX) doesn't have a **Nullable** type, so it uses **IReference** instead.

Other properties of an animation

The next properties described in this section are all optional in that they have defaults that are appropriate for most animations.

AutoReverse

If you don't specify either **AutoReverse** or **RepeatBehavior** on an animation, that animation will run once, and run for the time specified as the **Duration**.

The **AutoReverse** property specifies whether a timeline plays in reverse after it reaches the end of its **Duration**. If you set it to **true**, the animation reverses after it reaches the end of its declared **Duration**, changing the value from its ending value (**To**) back to its starting value (**From**). This means that the animation effectively runs for double the time of its **Duration**.

RepeatBehavior

The **RepeatBehavior** property specifies either how many times a timeline plays, or a larger duration that the timeline should repeat within. By default, a timeline has an iteration count of "1x", which means it plays one time for its **Duration** and does not repeat.

You can cause the animation to run multiple iterations. For example, a value of "3x" causes the animation to run three times. Or, you can specify a different **Duration** for **RepeatBehavior**. That **Duration** should be longer than the **Duration** of the animation itself to be effective. For example, if you specify a **RepeatBehavior** of "0:0:10", for an animation that has a **Duration** of "0:0:2", that animation repeats five times. If these don't divide evenly, the animation gets truncated at the time that the **RepeatBehavior** time is reached, which might be partway through. Finally, you can specify the special value "Forever", which causes the animation to run infinitely until it's deliberately stopped.

For more info about **RepeatBehavior** values and the XAML syntax, see **RepeatBehavior**.

FillBehavior="Stop"

By default, when an animation ends, the animation leaves the property value as the final **To** or **By**-modified value even after its duration is surpassed. However, if you set the value of the **FillBehavior** property to **FillBehavior.Stop**, the value of the animated value reverts to whatever the value was before the animation was applied, or more precisely to the current effective value as determined by the dependency property system (for more info on this distinction, see Dependency properties overview).

BeginTime

By default, the **BeginTime** of an animation is "0:0:0", so it begins as soon as its containing **Storyboard** runs. You might change this if the **Storyboard** contains more

than one animation and you want to stagger the start times of the others versus an initial animation, or to create a deliberate short delay.

SpeedRatio

If you have more than one animation in a Storyboard you can change the time rate of one or more of the animations relative to the **Storyboard**. It's the parent **Storyboard** that ultimately controls how the Duration time elapses while the animations run. This property isn't used very often. For more info see SpeedRatio.

Defining more than one animation in a Storyboard

The contents of a Storyboard can be more than one animation definition. You might have more than one animation if you are applying related animations to two properties of the same target object. For example, you might change both the TranslateX and TranslateY properties of a TranslateTransform used as the RenderTransform of a UI element; this will cause the element to translate diagonally. You need two different animations to accomplish that, but you might want the animations to be part of the same **Storyboard** because you always want those two animations to be run together.

The animations don't have to be the same type, or target the same object. They can have different durations, and don't have to share any property values.

When the parent Storyboard runs, each of the animations within will run too.

The Storyboard class actually has a lot of the same animation properties as the animation types do, because both share the Timeline base class. Thus, a **Storyboard** can have a RepeatBehavior, or a BeginTime. You don't usually set these on a **Storyboard** though unless you want all the contained animations to have that behavior. As a general rule, any **Timeline** property as set on a **Storyboard** applies to all its child animations. If let unset, the **Storyboard** has an implicit duration that's calculated from the longest Duration value of the contained animations. An explicitly set Duration on a **Storyboard** that's shorter than one of its child animations will cause that animation to get cut off, which isn't usually desirable.

A storyboard can't contain two animations that attempt to target and animate the same property on the same object. If you try this, you'll get a runtime error when the storyboard tries to run. This restriction applies even if the animations don't overlap in time because of deliberately different BeginTime values and durations. If you really want to apply a more complex animation timeline to the same property in a single

storyboard, the way to do this is to use a key-frame animation. See Key-frame and easing function animations.

The animation system can apply more than one animation to the value of a property, if those inputs come from multiple storyboards. Using this behavior deliberately for simultaneously running storyboards isn't common. However it's possible that an app-defined animation that you apply to a control property will be modifying the **HoldEnd** value of an animation that was previously run as part of the control's visual state model.

Defining a storyboard as a resource

A **Storyboard** is the container that you put animation objects in. You typically define the **Storyboard** as a resource that is available to the object that you want to animate, either in page-level **Resources** or **Application.Resources**.

This next example shows how the previous example **Storyboard** would be contained in a page-level **Resources** definition, where the **Storyboard** is a keyed resource of the root **Page**. Note the x:Name attribute. This attribute is how you define a variable name for the **Storyboard**, so that other elements in XAML as well as code can refer to the **Storyboard** later.

XAML

```
<Page ...>
  <Page.Resources>
    <!-- Storyboard resource: Animates a rectangle's opacity. -->
    <Storyboard x:Name="myStoryboard">
      <DoubleAnimation
        Storyboard.TargetName="MyAnimatedRectangle"
        Storyboard.TargetProperty="Opacity"
        From="1.0" To="0.0" Duration="0:0:1"/>
    </Storyboard>
  </Page.Resources>
  <!--Page root element, UI definition-->
  <Grid>
    <Rectangle x:Name="MyAnimatedRectangle"
      Width="300" Height="200" Fill="Blue"/>
  </Grid>
</Page>
```

Defining resources at the XAML root of a XAML file such as page.xaml or app.xaml is a common practice for how to organize keyed resources in your XAML. You also can factor resources into separate files and merge them into apps or pages. For more info, see ResourceDictionary and XAML resource references.

> **Note**
>
> Windows Runtime XAML supports identifying resources either using the x:Key attribute or the x:Name attribute. Using x:Name attribute is more common for a Storyboard, because you'll want to reference it by variable name eventually, so that you can call its Begin method and run the animations. If you do use x:Key attribute, you'll need to use ResourceDictionary methods such as the Item indexer to retrieve it as a keyed resource and then cast the retrieved object to **Storyboard** to use the **Storyboard** methods.

Storyboards for visual states

You also put your animations within a **Storyboard** unit when you are declaring the visual state animations for a control's visual appearance. In that case the **Storyboard** elements you define go into a **VisualState** container that's nested more deeply in a **Style** (it's the **Style** that is the keyed resource). You don't need a key or name for your **Storyboard** in this case because it's the **VisualState** that has a target name that the **VisualStateManager** can invoke. The styles for controls are often factored into separate XAML **ResourceDictionary** files rather than placed in a page or app **Resources** collection. For more info, see Storyboarded animations for visual states.

Dependent and independent animations

At this point we need to introduce some important points about how the animation system works. In particular, animation interacts fundamentally with how a Windows Runtime app renders to the screen, and how that rendering uses processing threads. A Windows Runtime app always has a main UI thread, and this thread is responsible for updating the screen with current information. In addition, a Windows Runtime app has a composition thread, which is used for precalculating layouts immediately before they are shown. When you animate the UI, there's potential to cause a lot of work for the UI thread. The system must redraw large areas of the screen using fairly short time intervals between each refresh. This is necessary for capturing the latest property value of the animated property. If you're not careful, there's risk that an animation can make the UI less responsive, or will impact performance of other app features that are also on the same UI thread.

The variety of animation that is determined to have some risk of slowing down the UI thread is called a *dependent animation*. An animation not subject to this risk is an *independent animation*. The distinction between dependent and independent animations isn't just determined by animation types (**DoubleAnimation** and so on) as

we described earlier. Instead, it's determined by which specific properties you are animating, and other factors like inheritance and composition of controls. There are circumstances where even if an animation does change UI, the animation can have minimal impact to the UI thread, and can instead be handled by the composition thread as an independent animation.

An animation is independent if it has any of these characteristics:

- The **Duration** of the animation is 0 seconds (see Warning)
- The animation targets **UIElement.Opacity**
- The animation targets a sub-property value of these **UIElement** properties: **Transform3D**, **RenderTransform**, **Projection**, **Clip**
- The animation targets **Canvas.Left** or **Canvas.Top**
- The animation targets a **Brush** value and uses a **SolidColorBrush**, animating its **Color**
- The animation is an **ObjectAnimationUsingKeyFrames**

> ⚠ **Warning**
>
> In order for your animation to be treated as independent, you must explicitly set `Duration="0"`. For example, if you remove `Duration="0"` from this XAML, the animation is treated as dependent, even though the **KeyTime** of the frame is "0:0:0".

XAML

```
<Storyboard>
  <DoubleAnimationUsingKeyFrames
    Duration="0"
    Storyboard.TargetName="Button2"
    Storyboard.TargetProperty="Width">
    <DiscreteDoubleKeyFrame KeyTime="0:0:0" Value="200"/>
  </DoubleAnimationUsingKeyFrames>
</Storyboard>
```

If your animation doesn't meet these criteria, it's probably a dependent animation. By default, the animation system won't run a dependent animation. So during the process of developing and testing, you might not even be seeing your animation running. You can still use this animation, but you must specifically enable each such dependent animation. To enable your animation, set the **EnableDependentAnimation** property of the animation object to **true**. (Each **Timeline** subclass that represents an animation has a different implementation of the property but they're all named `EnableDependentAnimation`.)

The requirement of enabling dependent animations falling onto the app developer is a conscious design aspect of the animation system and the development experience. We want developers to be aware that animations do have a performance cost for the responsiveness of your UI. Poorly performing animations are difficult to isolate and debug in a full-scale app. So it's better to turn on only the dependent animations you really need for your app's UI experience. We didn't want to make it too easy to compromise your app's performance because of decorative animations that use a lot of cycles. For more info on performance tips for animation, see Optimize animations and media.

As an app developer, you can also choose to apply an app-wide setting that always disables dependent animations, even those where **EnableDependentAnimation** is **true**. See **Timeline.AllowDependentAnimations**.

> **Tip**
>
> If you're using the Animation Pane in Blend for Visual Studio 2019, whenever you attempt to apply a dependent animation to a visual state property, warnings will be displayed in the designer. Warnings will not show in the build output or Error List. If you're editing XAML by hand, the designer will not show a warning. At runtime when debugging, the Output pane's Debug output will show a warning that the animation is not independent and will be skipped.

Starting and controlling an animation

Everything we've shown you so far doesn't actually cause an animation to run or be applied! Until the animation is started and is running, the value changes that an animation is declaring in XAML are latent and won't happen yet. You must explicitly start an animation in some way that's related to the app lifetime or the user experience. At the simplest level, you start an animation by calling the **Begin** method on the **Storyboard** that's the parent for that animation. You can't call methods from XAML directly, so whatever you do to enable your animations, you'll be doing it from code. That will either be the code-behind for the pages or components of your app, or perhaps the logic of your control if you're defining a custom control class.

Typically, you'll call **Begin** and just let the animation run to its duration completion. However, you can also use **Pause**, **Resume** and **Stop** methods to control the **Storyboard** at run-time, as well as other APIs that are used for more advanced animation control scenarios.

When you call **Begin** on a storyboard that contains an animation that repeats infinitely (`RepeatBehavior="Forever"`), that animation runs until the page containing it is unloaded, or you specifically call **Pause** or **Stop**.

Starting an animation from app code

You can either start animations automatically, or in response to user actions. For the automatic case, you typically use an object lifetime event such as **Loaded** to act as the animation trigger. The **Loaded** event is a good event to use for this because at that point the UI is ready for interaction, and the animation won't be cut off at the beginning because another part of UI was still loading.

In this example, the **PointerPressed** event is attached to the rectangle so that when the user clicks the rectangle, the animation begins.

XAML

```
<Rectangle PointerPressed="Rectangle_Tapped"
  x:Name="MyAnimatedRectangle"
  Width="300" Height="200" Fill="Blue"/>
```

The event handler start the **Storyboard** (the animation) by using the **Begin** method of the **Storyboard**.

C#

```
myStoryboard.Begin();
```

C++/WinRT

```
myStoryboard().Begin();
```

C++

```
myStoryboard->Begin();
```

VB

```
myStoryBoard.Begin()
```

You can handle the **Completed** event if you want other logic to run after the animation has finished applying values. Also, for troubleshooting property system/animation

interactions, the **GetAnimationBaseValue** method can be useful.

> **Tip**
>
> Whenever you are coding for an app scenario where you are starting an animation from app code, you might want to review again whether an animation or transition already exists in the animation library for your UI scenario. The library animations enable a more consistent UI experience across all Windows Runtime apps, and are easier to use.

Animations for visual states

The run behavior for a **Storyboard** that's used to define a control's visual state is different from how an app might run a storyboard directly. As applied to a visual state definition in XAML, the **Storyboard** is an element of a containing **VisualState**, and the state as a whole is controlled by using the **VisualStateManager** API. Any animations within will run according to their animation values and **Timeline** properties when the containing **VisualState** is used by a control. For more info, see Storyboards for visual states. For visual states, the apparent **FillBehavior** is different. If a visual state is changed to another state, all the property changes applied by the previous visual state and its animations are canceled, even if the new visual state doesn't specifically apply a new animation to a property.

Storyboard and EventTrigger

There is one way to start an animation that can be declared entirely in XAML. However, this technique isn't widely used anymore. It's a legacy syntax from WPF and early versions of Silverlight prior to **VisualStateManager** support. This **EventTrigger** syntax still works in Windows Runtime XAML for import/compatibility reasons, but only works for a trigger behavior based on the **FrameworkElement.Loaded** event; attempting to trigger off other events will throw exceptions or fail to compile. For more info, see **EventTrigger** or **BeginStoryboard**.

Animating XAML attached properties

It's not a common scenario, but you can apply an animated value to a XAML attached property. For more info on what attached properties are and how they work, see Attached properties overview. Targeting an attached property requires a property-path

syntax that encloses the property name in parentheses. You can animate the built-in attached properties such as **Canvas.ZIndex** by using an **ObjectAnimationUsingKeyFrames** that applies discrete integer values. However, an existing limitation of the Windows Runtime XAML implementation is that you cannot animate a custom attached property.

More animation types, and next steps for learning about animating your UI

Up to now, we've shown the custom animations that are animating between two values, and then linearly interpolating the values as necessary while the animation runs. These are called **From/To/By** animations. But there's another animation type that enables you to declare intermediate values that fall between the start and end. These are called *key-frame animations*. There's also a way to alter the interpolation logic on either a **From/To/By** animation or a key-frame animation. This involves applying an easing function. For more info on these concepts, see Key-frame and easing function animations.

Key-frame animations and easing function animations

Article • 06/24/2021

Linear key-frame animations, key-frame animations with a **KeySpline** value, or easing functions are three different techniques for approximately the same scenario: creating a storyboarded animation that's a bit more complex, and that uses a nonlinear animation behavior from a starting state to an end state.

Prerequisites

Make sure you've read the Storyboarded animations topic. This topic builds on the animation concepts that were explained in Storyboarded animations and won't go over them again. For example, Storyboarded animations describes how to target animations, storyboards as resources, the **Timeline** property values such as **Duration**, **FillBehavior**, and so on.

Animating using key-frame animations

Key-frame animations permit more than one target value that is reached at a point along the animation timeline. In other words, each key frame can specify a different intermediate value, and the last key frame reached is the final animation value. By specifying multiple values to animate, you can make more complex animations. Key-frame animations also enable different interpolation logic, which are each implemented as a different **KeyFrame** subclass per animation type. Specifically, each key-frame animation type has a **Discrete**, **Linear**, **Spline** and **Easing** variation of its **KeyFrame** class for specifying its key frames. For example, to specify an animation that targets a **Double** and uses key frames, you could declare key frames with **DiscreteDoubleKeyFrame**, **LinearDoubleKeyFrame**, **SplineDoubleKeyFrame**, and **EasingDoubleKeyFrame**. You can use any and all of these types within a single **KeyFrames** collection, to change the interpolation each time a new key frame is reached.

For interpolation behavior, each key frame controls the interpolation until its **KeyTime** time is reached. Its **Value** is reached at that time also. If there are more key frames beyond, the value then becomes the starting value for the next key frame in a sequence.

At the start of the animation, if no key frame with **KeyTime** of "0:0:0" exists, the starting value is whatever the non-animated value of the property is. This is similar to how a **From/To/By** animation acts if there is no **From**.

The duration of a key-frame animation is implicitly the duration equal to the highest **KeyTime** value set in any of its key frames. You can set an explicit **Duration** if you want, but be careful it's not shorter than a **KeyTime** in your own key frames or you'll cut off part of the animation.

In addition to **Duration**, you can set all the **Timeline** based properties on a key-frame animation, like you can with a **From/To/By** animation, because the key-frame animation classes also derive from **Timeline**. These are:

- **AutoReverse**: once the last key frame is reached, the frames are repeated in reverse order from the end. This doubles the apparent duration of the animation.
- **BeginTime**: delays the start of the animation. The timeline for the **KeyTime** values in the frames doesn't start counting until **BeginTime** is reached, so there's no risk of cutting off frames
- **FillBehavior**: controls what happens when the last key frame is reached. **FillBehavior** has no effect on any intermediate key frames.
- **RepeatBehavior**:
  - If set to **Forever**, then the key frames and their timeline repeat infinitely.
  - If set to an iteration count, the timeline repeats that many times.
  - If set to a **Duration**, the timeline repeats until that time is reached. This might truncate the animation part way through the key frame sequence, if it's not an integer factor of the timeline's implicit duration.
- **SpeedRatio** (not commonly used)

Linear key frames

Linear key frames result in a simple linear interpolation of the value until the frame's **KeyTime** is reached. This interpolation behavior is the most similar to the simpler **From/To/By** animations described in the Storyboarded animations topic.

Here's how to use a key-frame animation to scale the render height of a rectangle, using linear key frames. This example runs an animation where the height of the rectangle increases slightly and linearly for the first 4 seconds, then scales rapidly for the last second until the rectangle is double the starting height.

XML

```
<StackPanel>
    <StackPanel.Resources>
        <Storyboard x:Name="myStoryboard">
            <DoubleAnimationUsingKeyFrames
              Storyboard.TargetName="myRectangle"
              Storyboard.TargetProperty="(UIElement.RenderTransform).
(ScaleTransform.ScaleY)">
```

```
                <LinearDoubleKeyFrame Value="1" KeyTime="0:0:0"/>
                <LinearDoubleKeyFrame Value="1.2" KeyTime="0:0:4"/>
                <LinearDoubleKeyFrame Value="2" KeyTime="0:0:5"/>
            </DoubleAnimationUsingKeyFrames>
        </Storyboard>
    </StackPanel.Resources>
</StackPanel>
```

Discrete key frames

Discrete key frames don't use any interpolation at all. When a **KeyTime** is reached, the new **Value** is simply applied. Depending on which UI property is being animated, this often produces an animation that appears to "jump". Be certain that this is the aesthetic behavior that you really want. You can minimize the apparent jumps by increasing the number of key frames you declare, but if a smooth animation is your goal, you might be better off using linear or spline key frames instead.

> **Note**
>
> Discrete key frames are the only way to animate a value that isn't of type **Double**, **Point**, and **Color**, with a **DiscreteObjectKeyFrame**. We'll discuss this in more detail later in this topic.

Spline key frames

A spline key frame creates a variable transition between values according to the value of the **KeySpline** property. This property specifies the first and second control points of a Bezier curve, which describes the acceleration of the animation. Basically, a **KeySpline** defines a function-over-time relationship where the function-time graph is the shape of that Bezier curve. You typically specify a **KeySpline** value in a XAML shorthand attribute string that has four **Double** values separated by spaces or commas. These values are "X,Y" pairs for two control points of the Bezier curve. "X" is time and "Y" is the function modifier to the value. Each value should always be between 0 and 1 inclusive. Without control point modification to a **KeySpline**, the straight line from 0,0 to 1,1 is the representation of a function over time for a linear interpolation. Your control points change the shape of that curve and thus the behavior of the function over time for the spline animation. It's probably best to see this visually as a graph. You can run the Silverlight key-spline visualizer sample in a browser to see how the control points modify the curve and how a sample animation runs when using it as a **KeySpline** value.

This next example shows three different key frames applied to an animation, with the last one being a key spline animation for a **Double** value (**SplineDoubleKeyFrame**). Note the string "0.6,0.0 0.9,0.00" applied for **KeySpline**. This produces a curve where the animation appears to run slowly at first but then rapidly reaches the value just before the **KeyTime** is reached.

XML

```
<Storyboard x:Name="myStoryboard">
    <!-- Animate the TranslateTransform's X property
        from 0 to 350, then 50,
        then 200 over 10 seconds. -->
    <DoubleAnimationUsingKeyFrames
        Storyboard.TargetName="MyAnimatedTranslateTransform"
        Storyboard.TargetProperty="X"
        Duration="0:0:10" EnableDependentAnimation="True">

        <!-- Using a LinearDoubleKeyFrame, the rectangle moves
            steadily from its starting position to 500 over
            the first 3 seconds.  -->
        <LinearDoubleKeyFrame Value="500" KeyTime="0:0:3"/>

        <!-- Using a DiscreteDoubleKeyFrame, the rectangle suddenly
            appears at 400 after the fourth second of the animation. -->
        <DiscreteDoubleKeyFrame Value="400" KeyTime="0:0:4"/>

        <!-- Using a SplineDoubleKeyFrame, the rectangle moves
            back to its starting point. The
            animation starts out slowly at first and then speeds up.
            This KeyFrame ends after the 6th second. -->
        <SplineDoubleKeyFrame KeySpline="0.6,0.0 0.9,0.00" Value="0"
KeyTime="0:0:6"/>
    </DoubleAnimationUsingKeyFrames>
</Storyboard>
```

Easing key frames

An easing key frame is a key frame where interpolation is being applied, and the function over time of the interpolation is controlled by several pre-defined mathematical formulas. You can actually produce much the same result with a spline key frame as you can with some of the easing function types, but there are also some easing functions, such as **BackEase**, that you can't reproduce with a spline.

To apply an easing function to an easing key frame, you set the **EasingFunction** property as a property element in XAML for that key frame. For the value, specify an object element for one of the easing function types.

This example applies a CubicEase and then a BounceEase as successive key frames to a DoubleAnimation to create a bouncing effect.

XML

```
<Storyboard x:Name="myStoryboard">
    <DoubleAnimationUsingKeyFrames Duration="0:0:10"
        Storyboard.TargetProperty="Height"
        Storyboard.TargetName="myEllipse">

        <!-- This keyframe animates the ellipse up to the crest
            where it slows down and stops. -->
        <EasingDoubleKeyFrame Value="-300" KeyTime="00:00:02">
            <EasingDoubleKeyFrame.EasingFunction>
                <CubicEase/>
            </EasingDoubleKeyFrame.EasingFunction>
        </EasingDoubleKeyFrame>

        <!-- This keyframe animates the ellipse back down and makes
            it bounce. -->
        <EasingDoubleKeyFrame Value="0" KeyTime="00:00:06">
            <EasingDoubleKeyFrame.EasingFunction>
                <BounceEase Bounces="5"/>
            </EasingDoubleKeyFrame.EasingFunction>
        </EasingDoubleKeyFrame>
    </DoubleAnimationUsingKeyFrames>
</Storyboard>
```

This is just one easing function example. We'll cover more in the next section.

Easing functions

Easing functions allow you to apply custom mathematical formulas to your animations. Mathematical operations are often useful to produce animations that simulate real-world physics in a 2-D coordinate system. For example, you may want an object to realistically bounce or behave as though it were on a spring. You could use key frame or even **From/To/By** animations to approximate these effects but it would take a significant amount of work and the animation would be less accurate than using a mathematical formula.

Easing functions can be applied to animations in three ways:

- By using an easing keyframe in a keyframe animation, as described in the previous section. Use EasingColorKeyFrame.EasingFunction, EasingDoubleKeyFrame.EasingFunction, or EasingPointKeyFrame.EasingFunction.
- By setting the **EasingFunction** property on one of the **From/To/By** animation types. Use ColorAnimation.EasingFunction, DoubleAnimation.EasingFunction or

PointAnimation.EasingFunction.

- By setting GeneratedEasingFunction as part of a VisualTransition. This is specific to defining visual states for controls; for more info, see GeneratedEasingFunction or Storyboards for visual states.

Here is a list of the easing functions:

- BackEase: Retracts the motion of an animation slightly before it begins to animate in the path indicated.
- BounceEase: Creates a bouncing effect.
- CircleEase: Creates an animation that accelerates or decelerates using a circular function.
- CubicEase: Creates an animation that accelerates or decelerates using the formula f(t) = t3.
- ElasticEase: Creates an animation that resembles a spring oscillating back and forth until it comes to rest.
- ExponentialEase: Creates an animation that accelerates or decelerates using an exponential formula.
- PowerEase: Creates an animation that accelerates or decelerates using the formula f(t) = tp where p is equal to the Power property.
- QuadraticEase: Creates an animation that accelerates or decelerates using the formula f(t) = t2.
- QuarticEase: Creates an animation that accelerates or decelerates using the formula f(t) = t4.
- QuinticEase: Create an animation that accelerates or decelerates using the formula f(t) = t5.
- SineEase: Creates an animation that accelerates or decelerates using a sine formula.

Some of the easing functions have their own properties. For example, BounceEase has two properties Bounces and Bounciness that modify the function-over-time behavior of that particular **BounceEase**. Other easing functions such as CubicEase don't have properties other than the EasingMode property that all easing functions share, and always produce the same function-over-time behavior.

Some of these easing functions have a bit of overlap, depending on how you set properties on the easing functions that have properties. For example, QuadraticEase is exactly the same as a PowerEase with Power equal to 2. And CircleEase is basically a default-value ExponentialEase.

The BackEase easing function is unique because it can change the value outside of the normal range as set by **From**/**To** or values of key frames. It starts the animation by

changing the value in the opposite direction as would be expected from a normal **From/To** behavior, goes back to the **From** or starting value again, and then runs the animation as normal.

In an earlier example, we showed how to declare an easing function for a key-frame animation. This next sample applies an easing function to a **From/To/By** animation.

XML

```
<StackPanel x:Name="LayoutRoot" Background="White">
    <StackPanel.Resources>
        <Storyboard x:Name="myStoryboard">
            <DoubleAnimation From="30" To="200" Duration="00:00:3"
                Storyboard.TargetName="myRectangle"
                Storyboard.TargetProperty="(UIElement.RenderTransform).
(ScaleTransform.ScaleY)">
                <DoubleAnimation.EasingFunction>
                    <BounceEase Bounces="2" EasingMode="EaseOut"
                                Bounciness="2"/>
                </DoubleAnimation.EasingFunction>
            </DoubleAnimation>
        </Storyboard>
    </StackPanel.Resources>
    <Rectangle x:Name="myRectangle" Fill="Blue" Width="200" Height="30"/>
</StackPanel>
```

When an easing function is applied to a **From/To/By** animation, it's changing the function- over-time characteristics of how the value interpolates between the **From** and **To** values over the **Duration** of the animation. Without an easing function, that would be a linear interpolation.

Discrete object value animations

One type of animation deserves special mention because it's the only way you can apply an animated value to properties that aren't of type **Double**, **Point**, or **Color**. This is the key-frame animation **ObjectAnimationUsingKeyFrames**. Animating using **Object** values is different because there's no possibility of interpolating the values between the frames. When the frame's **KeyTime** is reached, the animated value is immediately set to the value specified in the key frame's **Value**. Because there's no interpolation, there's only one key frame you use in the **ObjectAnimationUsingKeyFrames** key frames collection: **DiscreteObjectKeyFrame**.

The **Value** of a **DiscreteObjectKeyFrame** is often set using property element syntax, because the object value you are trying to set often is not expressible as a string to fill

Value in attribute syntax. You can still use attribute syntax if you use a reference such as StaticResource.

One place you'll see an **ObjectAnimationUsingKeyFrames** used in the default templates is when a template property references a **Brush** resource. These resources are **SolidColorBrush** objects, not just a **Color** value, and they use resources that are defined as system themes (**ThemeDictionaries**). They can be assigned directly to a **Brush**-type value such as **TextBlock.Foreground** and don't need to use indirect targeting. But because a **SolidColorBrush** is not **Double**, **Point**, or **Color**, you have to use a **ObjectAnimationUsingKeyFrames** to use the resource.

XML

```
<Style x:Key="TextButtonStyle" TargetType="Button">
    <Setter Property="Template">
        <Setter.Value>
            <ControlTemplate TargetType="Button">
                <Grid Background="Transparent">
                    <TextBlock x:Name="Text"
                        Text="{TemplateBinding Content}"/>
                    <VisualStateManager.VisualStateGroups>
                        <VisualStateGroup x:Name="CommonStates">
                            <VisualState x:Name="Normal"/>
                            <VisualState x:Name="PointerOver">
                                <Storyboard>
                                    <ObjectAnimationUsingKeyFrames
Storyboard.TargetName="Text" Storyboard.TargetProperty="Foreground">
                                        <DiscreteObjectKeyFrame KeyTime="0"
Value="{StaticResource ApplicationPointerOverForegroundThemeBrush}"/>
                                    </ObjectAnimationUsingKeyFrames>
                                </Storyboard>
                            </VisualState>
                            <VisualState x:Name="Pressed">
                                <Storyboard>
                                    <ObjectAnimationUsingKeyFrames
Storyboard.TargetName="Text" Storyboard.TargetProperty="Foreground">
                                        <DiscreteObjectKeyFrame KeyTime="0"
Value="{StaticResource ApplicationPressedForegroundThemeBrush}"/>
                                    </ObjectAnimationUsingKeyFrames>
                                </Storyboard>
                            </VisualState>
...
                        </VisualStateGroup>
                    </VisualStateManager.VisualStateGroups>
                </Grid>
            </ControlTemplate>
        </Setter.Value>
    </Setter>
</Style>
```

You also might use **ObjectAnimationUsingKeyFrames** to animate properties that use an enumeration value. Here's another example from a named style that comes from the Windows Runtime default templates. Note how it sets the **Visibility** property that takes a **Visibility** enumeration constant. In this case you can set the value using attribute syntax. You only need the unqualified constant name from an enumeration for setting a property with an enumeration value, for example "Collapsed".

XML

```
<Style x:Key="BackButtonStyle" TargetType="Button">
    <Setter Property="Template">
      <Setter.Value>
        <ControlTemplate TargetType="Button">
          <Grid x:Name="RootGrid">
            <VisualStateManager.VisualStateGroups>
              <VisualStateGroup x:Name="CommonStates">
              <VisualState x:Name="Normal"/>
...           <VisualState x:Name="Disabled">
                <Storyboard>
                  <ObjectAnimationUsingKeyFrames
Storyboard.TargetName="RootGrid" Storyboard.TargetProperty="Visibility">
                    <DiscreteObjectKeyFrame Value="Collapsed" KeyTime="0"/>
                  </ObjectAnimationUsingKeyFrames>
                </Storyboard>
              </VisualState>
            </VisualStateGroup>
...
          </VisualStateManager.VisualStateGroups>
        </Grid>
      </ControlTemplate>
    </Setter.Value>
  </Setter>
</Style>
```

You can use more than one **DiscreteObjectKeyFrame** for an **ObjectAnimationUsingKeyFrames** frame set. This might be an interesting way to create a "slide show" animation by animating the value of **Image.Source**, as an example scenario for where multiple object values might be useful.

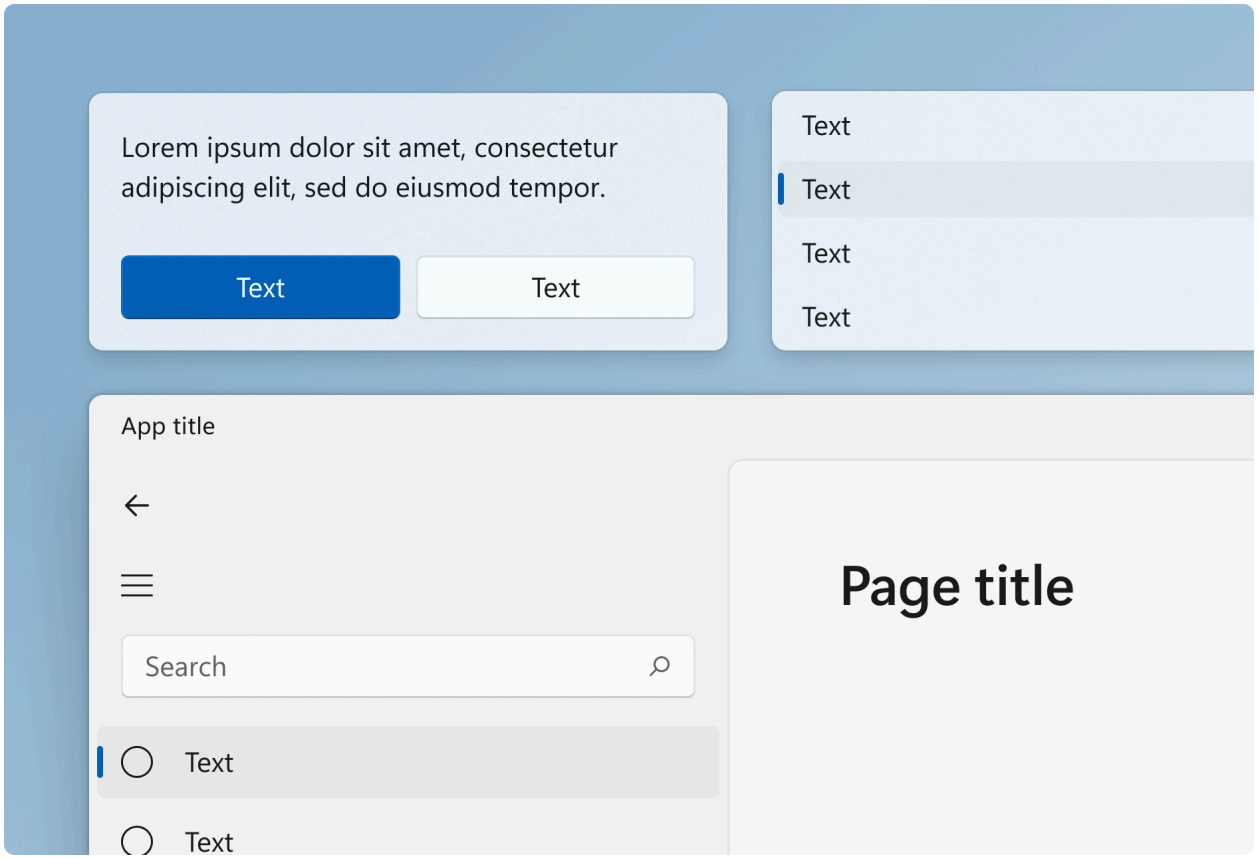
Geometry in Windows

Article • 11/05/2024

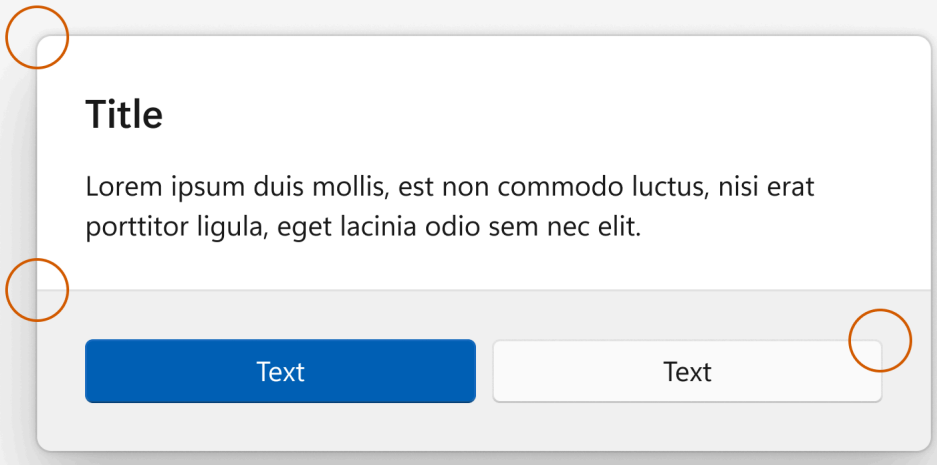


Geometry describes the shape, size and position of UI elements on screen. These fundamental design elements help experiences feel coherent across the entire design system.

Windows geometry has been crafted to support modern app experiences. Progressively rounded corners, nested elements, and consistent gutters combine to create a soft, calm, and approachable effect that emphasizes unity of purpose and ease of use.

> **Tip**
>
> This article describes how the Fluent Design language is applied to Windows apps. For more information, see Fluent Design - Shapes.

Rounded corners



Windows 11 applies rounded corners to all top-level app windows. The same applies to most common controls such as Button and ListView. (For more information, see Use the latest common controls.)

Windows 11 uses three levels of rounding depending on what UI component is being rounded and how that component is arranged relative to neighboring elements.

Expand table

Corner radius	Usage
8px	Top-level containers such as app windows, flyouts and dialogs are rounded using an 8px corner radius.
4px	In-page elements such as buttons and list backplates are rounded using a 4px corner radius.
0px	Straight edges that intersect with other straight edges are not rounded.
0px	Window corners are not rounded when windows are snapped or maximized.

Corner radius

Article • 03/23/2022

Starting with version 2.2 of WinUI, the default style for many controls has been updated to use rounded corners. These new styles are intended to evoke warmth and trust, and make the UI easier for users to visually process.

Here are two Button controls, the first without rounded corners and the second using a rounded corner style.

WinUI provides you with the updated styles for both WinUI and platform controls. See Customization options, for details on how to customize rounded corners.

> **ⓘ Important**
>
> Some controls are available both in the platform (Windows.UI.Xaml.Controls) and in WinUI (Microsoft.UI.Xaml.Controls); for example, **TreeView** or **ColorPicker**. When you use WinUI in your app, you should use the WinUI version of the control. Corner rounding might be applied inconsistently in the platform version when used with WinUI.

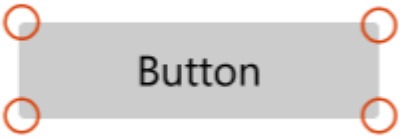
> **Important APIs**: Control.CornerRadius property

Default control designs

There are three areas of the controls where the rounded corner styles are used: rectangular elements, flyout elements, and bar elements.

Corners of rectangle UI elements

- These UI elements include basic controls like buttons that users see on screen at all times.
- The default radius value we use for these UI elements is **4px**.



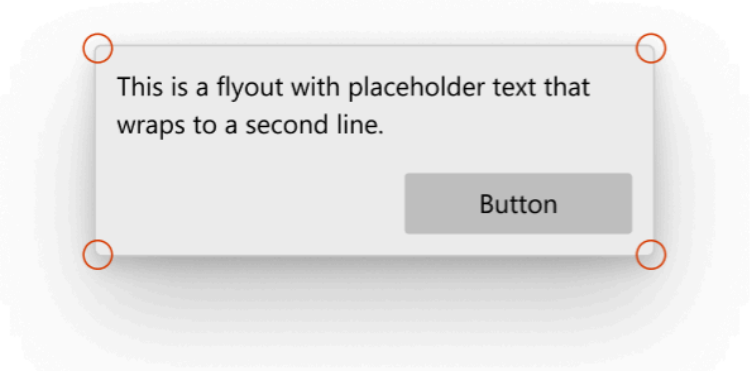
Controls

- AutoSuggestBox
- Buttons
  - ContentDialog buttons
- CalendarDatePicker
- CheckBox
  - TreeView, GridView, and ListView multi-select check boxes
- Color picker
- CommandBar
- ComboBox
- DatePicker
- DropDownButton
- Expander
- FlipView
- GridView and ListView
  - AutoSuggestBox, ComboBox, DatePicker, MenuBar, NavigationView, TimePicker, TreeView list
- InfoBar
- Inking controls
- Media playback
- MenuBar
- NumberBox
- PasswordBox
- RichEditBox
- SplitButton
- TextBox
- TimePicker
- ToggleButton
- ToggleSplitButton

Corners of flyout and overlay UI elements

- These can be transient UI elements that appear on screen temporarily, like MenuFlyout, or elements that overlay other UI, like TabView tabs.

- The default radius value we use for these UI elements is **8px**.



Controls

- CommandBarFlyout
- ContentDialog
- Flyout
- MenuFlyout
- TabView tabs
- TeachingTip
- ToolTip (uses **4px** radius due to small size)
- Flyout part (when open)
  - AutoSuggestBox
  - CalendarDatePicker
  - ComboBox
  - DatePicker
  - DropDownButton
  - Inking control
  - MenuBar
  - NumberBox
  - SplitButton
  - TimePicker
  - ToggleSplitButton

Bar elements

- These UI elements are shaped like bars or lines; for example, ProgressBar.
- The default radius values we use here are **4px**.

Controls

- NavigationView selection indicator
- ProgressBar
- ScrollBar
- Slider
  - ColorPicker color slider
  - MediaTransportControls seek bar slider

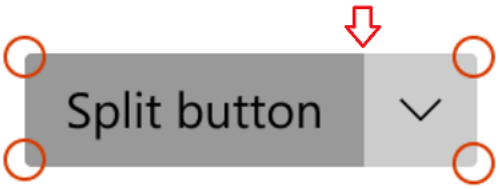
Customization options

The default corner radii values that we provide are not set in stone and there are a few ways you can easily modify the amount of rounding on the corners. This can be done through two global resources, or through the CornerRadius property directly on the control, depending on the level of customization granularity you want.

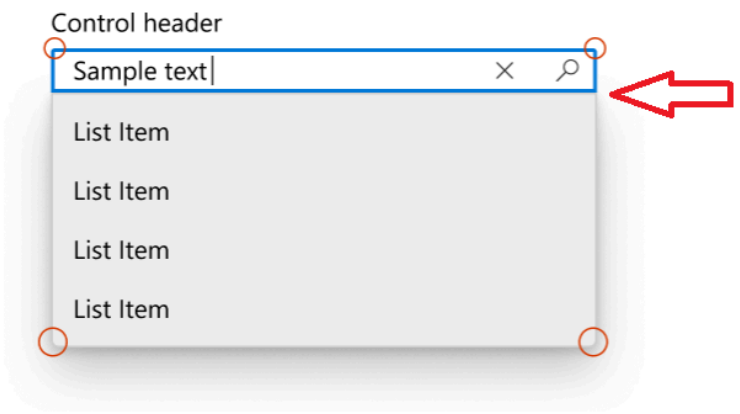
When not to round

There are instances where the corner of a control should not be rounded, and we don't round these by default.

- When multiple UI elements that are housed inside a container touch each other, such as the two parts of a SplitButton. There should be no space when they contact.



- When a flyout UI element is connected to a UI that invokes the flyout on one side.



Page or app-wide CornerRadius changes

There are 2 app resources that control the corner radii of all the controls:

- `ControlCornerRadius` - default is 4px.
- `OverlayCornerRadius` - default is 8px.

If you override the value of these resources at any scope, it will affect all controls within that scope accordingly.

This means if you want to change the roundness of all controls where roundness could be applied, you can define both resources at the app level with the new CornerRadius values like this:

XAML

```
<Application
    xmlns="http://schemas.microsoft.com/winfx/2006/xamlpresentation"
    xmlns:x="http://schemas.micosoft.com/winfx/2006/xaml"
    xmlns:control="using:Microsoft.UI.Xaml.Controls">
    <Application.Resources>
      <controls:XamlControlsResources>
        <controls:XamlControlsResources.MergedDictionaries>
          <ResourceDictionary>
            <CornerRadius x:Key="OverlayCornerRadius">0</CornerRadius>
            <CornerRadius x:Key="ControlCornerRadius">0</CornerRadius>
          </ResourceDictionary>
        </controls:XamlControlsResources.MergedDictionaries>
      </controls:XamlControlsResources>
    </Application.Resources>
</Application>
```

Alternatively, if you want to change all controls' roundness within a particular scope, like at a page or container level, you can follow a similar pattern:

XAML

```
<Grid>
    <Grid.Resources>
        <CornerRadius x:Key="ControlCornerRadius">8</CornerRadius>
    </Grid.Resources>
    <Button Content="Button"/>
</Grid>
```

> **Note**
>
> The `OverlayCornerRadius` resource must be defined at the app level in order to take effect.
>
> This is because popup and flyouts are not in to the page's visual tree, they are added to the Popup Root. The resource resolution system does not properly traverse the Popup Root visual tree into the Page's visual tree.

Per-control CornerRadius changes

You can modify the CornerRadius property on controls directly if you want to change the roundness of only a select number of controls.

Expand table

Default	Property modified
	`<CheckBox Content="Checkbox"/>`	`<CheckBox Content="Checkbox" CornerRadius="5"/>`

Not all controls' corners will respond to their `CornerRadius` property being modified. To ensure that the control whose corners you wish to round will indeed respond to their `CornerRadius` property the way you expect, first check that the `ControlCornerRadius` or `OverlayCornerRadius` global resources affect the control in question. If they do not, check that the control you wish to round has corners at all. Many of our controls do not render actual edges and therefore cannot make proper use of the `CornerRadius` property.

Basing custom styles on WinUI

You can base your custom styles on the WinUI rounded corner styles by specifying the correct `BasedOn` attribute in your style. For example to create a custom button style based on WinUI button style, do the following:

XAML

```
<Style x:Key="MyCustomButtonStyle" BasedOn="{StaticResource
DefaultButtonStyle}">
    ...
</Style>
```

In general, WinUI control styles follow a consistent naming convention: "DefaultXYZStyle" where "XYZ" is the name of the control. For full reference, you can browse the XAML files in the WinUI repository.

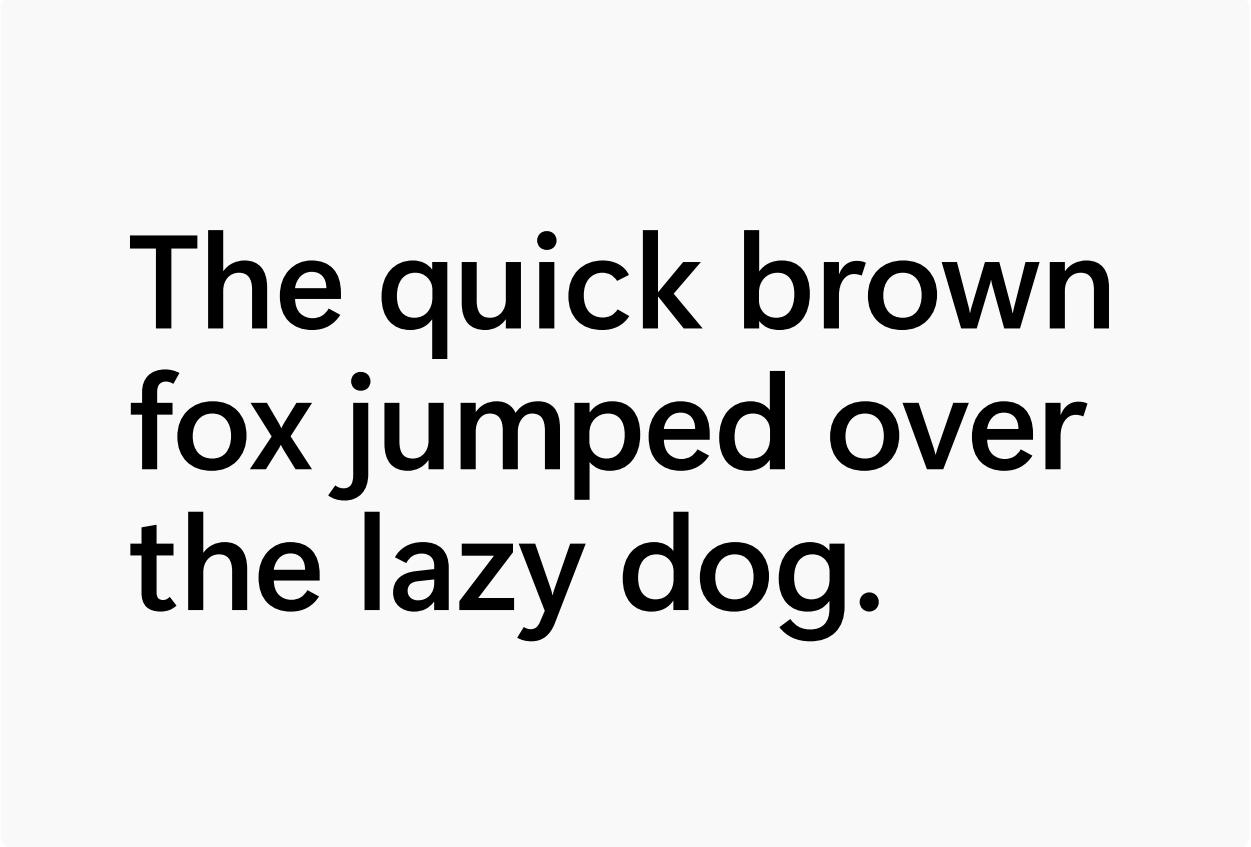
Typography in Windows

Article • 11/05/2024



As the visual representation of language, typography's main task is to communicate information. The Windows type system helps you create structure and hierarchy in your content in order to maximize legibility and readability in your UI.

Segoe UI Variable is the new system font for Windows. It is a refreshed take on the classic Segoe and uses variable font technology to dynamically provide great legibility at very small sizes, and improved outlines at display sizes.

> **Tip**
>
> This article describes how the **Fluent Design language** is applied to Windows apps. For more information, see **Fluent Design - Typography**.

Using Segoe Fluent Variable

Segoe UI Variable supports two axes for finer control of text: **weight** and **optical size**.

- The weight axis (`wght`) is incremental with weights from Thin (100) to Bold (700).

- The optical size axis (`opsz`) is automatic and on by default. It controls the shape and size of the counters in the font, to prioritize legibility at the small sizes and personality at the large sizes (for optical scaling from 8pt to 36pt).

When using XAML common controls, the Segoe UI Variable font will be selected by default for supported languages. When this font or another variable font with an optical axis is used, the optical size will automatically match the requested font-size. When using HTML, optical scaling is also automatic, but you will need to specify the Segoe UI Variable font in CSS.

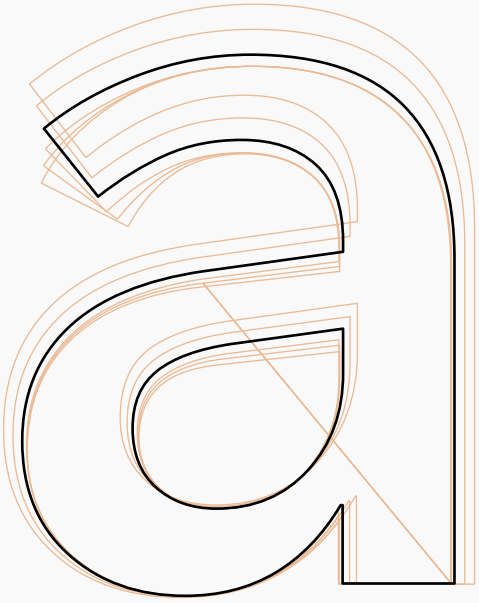
Weights

Expand table

Weight name	Weight axis value	Visual
Light	300	
Semilight	350	
Regular	400	
Semibold	600	

Weight name	Weight axis value	Visual
Bold	700	Segoe

Optical axis



Typography best practices in Windows 11

Windows 11 uses Segoe UI Variable with the following attributes based on the context in which the text is being displayed.

Expand table

Attribute	Value	Notes
Weight	Regular, Semibold	Use regular weight for most text, use Semibold for titles
Alignment	Left, Center	Align left by default, Align center only in rare cases such as text below icons
Minimum values	14px Semibold, 12px Regular	Text smaller than these sizes and weights are illegible in some languages
Casing	Sentence case	Use sentence casing for all UI text, including titles
Truncation	Ellipses and clipping	Use ellipses in most cases; clipping is only used in rare cases

Examples

Open the WinUI 3 Gallery app and see Typography principles in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

Typography in Windows Apps

As the visual representation of language, typography's main task is to communicate information. Its style should never get in the way of that goal. In this article, we'll discuss how to style typography in your Windows app to help users understand content easily and efficiently.

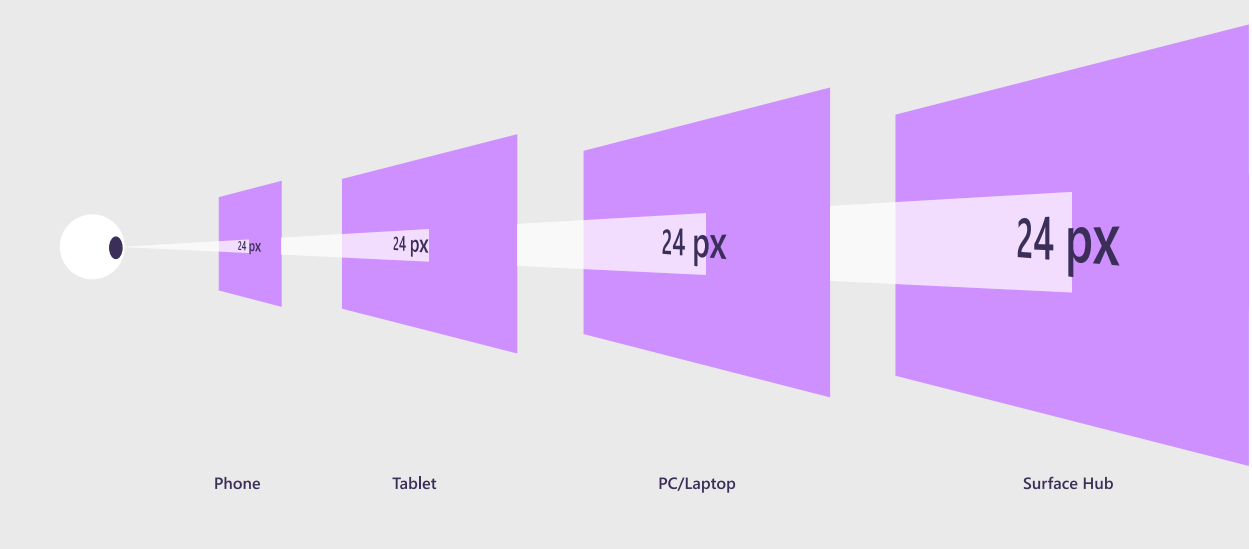
Font

You should use one font throughout your app's UI, and we recommend sticking with the default font for Windows apps, **Segoe UI Variable**. It's designed to maintain optimal legibility across sizes and pixel densities and offers a clean, light, and open aesthetic that complements the content of the system.

To display non-English languages or to select a different font for your app, please see Languages and Fonts for our recommended fonts for Windows apps.

Size and scaling

Font sizes in XAML apps automatically scale on all devices. The scaling algorithm ensures that a 24 px font on a large screen 10 feet away is just as legible as a 24 px font on a small screen that's a few inches away.



Because of how the scaling system works, you're designing in effective pixels, not actual physical pixels, and you shouldn't have to alter font sizes for different screens sizes or resolutions.

Hierarchy

Users rely on visual hierarchy when scanning a page: headers summarize content, and body text provides more detail. To create a clear visual hierarchy in your app, follow the Windows type ramp.

Type Hierarchy

Hierarchy

lets the reader know where to look first

Hierarchy can be created by using size, weight, color and spacing

Type ramp

The Windows type ramp establishes crucial relationships between the type styles on a page, helping users read content easily. All sizes are in effective pixels and are optimized for Windows apps running on all screen sizes.

Windows 11 uses the following values for various types of text in the UI.

Expand table

Example	Weight	Size/line height
Caption	Small	12/16 epx
Body	Text	14/20 epx
Body Strong	Text semibold	14/20 epx
Body Large	Text	18/24 epx
Subtitle	Display semibold	20/28 epx
Title	Display semibold	28/36 epx
Title Large	Display semibold	40/52 epx

Example	Weight	Size/line height
Display	Display semibold	68/92 epx

Check out the guidance on using the XAML type ramp for more details.

Alignment

The default TextAlignment is Left, and in most instances, flush-left and ragged right provides consistent anchoring of the content and a uniform layout. For RTL languages, see Adjusting layout and fonts to support globalization.

Flush-left text is aligned along the left margin or gutter, also known as left-aligned or ragged right. Ensure even line endings or rag when setting flush-left text.

XAML

```
<TextBlock TextAlignment="Left">
```

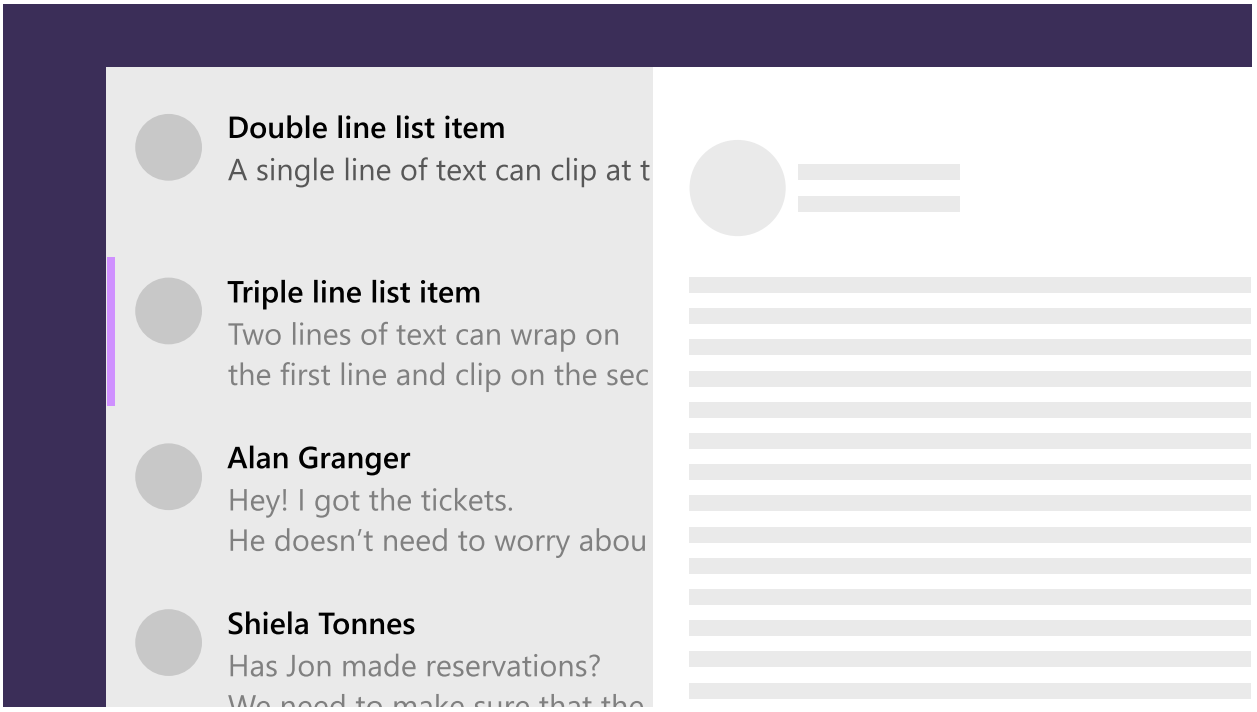
Character count

✓ Do Keep to 50–60 letters per line for ease of reading.

✗ Don't Don't use fewer than 20 characters or more than 60 characters per line as this is difficult to read.

Clipping and ellipses

When the amount of text extends beyond the space available, we recommend clipping the text and inserting ellipses [...], which is the default behavior of most UWP text controls.



XAML

```
<TextBlock TextWrapping="WrapWholeWords" TextTrimming="Clip"/>
```

✓ Do Clip text, and wrap if multiple lines are enabled.

✗ Don't Don't use ellipses to avoid visual clutter.

> **Note**
>
> If containers are not well-defined (for example, no differentiating background color), or when there is a link to see more text, then use ellipses.

Languages

Segoe UI Variable is our font for English, European languages, Greek, and Russian. For other languages, see the following recommendations.

Globalizing/localizing fonts

Use the LanguageFont font-mapping APIs for programmatic access to the recommended font family, size, weight, and style for a particular language. The LanguageFont object provides access to the correct font info for various categories of content including UI headers, notifications, body text, and user-editable document body fonts. For more info, see Adjusting layout and fonts to support globalization.

Fonts for non-Latin languages

Expand table

Font-family	Styles	Notes
Ebrima	Regular, Bold	User-interface font for African scripts (ADLaM, Ethiopic, N'Ko, Osmanya, Tifinagh, Vai).
Gadugi	Regular, Bold	User-interface font for North American scripts (Canadian Syllabics, Cherokee, Osage).
Leelawadee UI	Regular, Semilight, Bold	User-interface font for Southeast Asian scripts (Buginese, Khmer, Lao, Thai).
Malgun Gothic	Regular	User-interface font for Korean.
Microsoft JhengHei UI	Regular, Bold, Light	User-interface font for Traditional Chinese.
Microsoft YaHei UI	Regular, Bold, Light	User-interface font for Simplified Chinese.
Myanmar Text	Regular	Fallback font for Myanmar script.
Nirmala UI	Regular, Semilight, Bold	User-interface font for South Asian scripts (Bangla, Chakma, Devanagari, Gujarati, Gurmukhi, Kannada, Malayalam, Meetei Mayek, Odia, Ol Chiki, Sinhala, Sora Sompeng, Tamil, Telugu).
Segoe UI	Regular, Italic, Light Italic, Black Italic, Bold, Bold Italic, Light, Semilight, Semibold, Black	User-interface font for Arabic, Armenian, Georgian, and Hebrew.

Font-family	Styles	Notes
SimSun	Regular	A legacy Chinese UI font.
Yu Gothic UI	Light, Semilight, Regular, Semibold, Bold	User-interface font for Japanese.

Fonts

Sans-serif fonts

Sans-serif fonts are a great choice for headings and UI elements.

Expand table

Font-family	Styles	Notes
Arial	Regular, Italic, Bold, Bold Italic, Black	Supports European and Middle Eastern scripts (Latin, Greek, Cyrillic, Arabic, Armenian, and Hebrew). Black weight supports European scripts only.
Calibri	Regular, Italic, Bold, Bold Italic, Light, Light Italic	Supports European and Middle Eastern scripts (Latin, Greek, Cyrillic, Arabic and Hebrew). Arabic available in the uprights only.
Consolas	Regular, Italic, Bold, Bold Italic	Fixed width font that supports European scripts (Latin, Greek and Cyrillic).
Segoe UI	Regular, Italic, Light Italic, Black Italic, Bold, Bold Italic, Light, Semilight, Semibold, Black	User-interface font for European and Middle East scripts (Arabic, Armenian, Cyrillic, Georgian, Greek, Hebrew, Latin), and also Lisu script.
Selawik	Regular, Semilight, Light, Bold, Semibold	An open-source font that's metrically compatible with Segoe UI, intended for apps on other platforms that don't want to bundle Segoe UI. Get Selawik on GitHub.

Serif fonts

Serif fonts are good for presenting large amounts of text.

Expand table

Font-family	Styles	Notes
Cambria	Regular	Serif font that supports European scripts (Latin, Greek, Cyrillic).
Courier New	Regular, Italic, Bold, Bold Italic	Serif fixed width font that supports European and Middle Eastern scripts (Latin, Greek, Cyrillic, Arabic, Armenian, and Hebrew).
Georgia	Regular, Italic, Bold, Bold Italic	Supports European scripts (Latin, Greek and Cyrillic).
Times New Roman	Regular, Italic, Bold, Bold Italic	Legacy font that supports European scripts (Latin, Greek, Cyrillic, Arabic, Armenian, Hebrew).

Variable fonts

Variable fonts are good for precisely controlling the appearance of text.

Expand table

Font-family	Axes	Notes
Bahnschrift	Weight, Width	Variable font that supports Latin, Greek, and Cyrillic.
Segoe UI Variable	Weight, Optical Size	Variable font that supports Latin, Greek, and Cyrillic.

Symbols and icons

Expand table

Font-family	Styles	Notes
Segoe MDL2 Assets	Regular	User-interface font for app icons. For more info, see the Segoe Fluent Icons font article.
Segoe UI Emoji	Regular	User-interface font for Emoji.
Segoe UI Symbol	Regular	Fallback font for symbols.

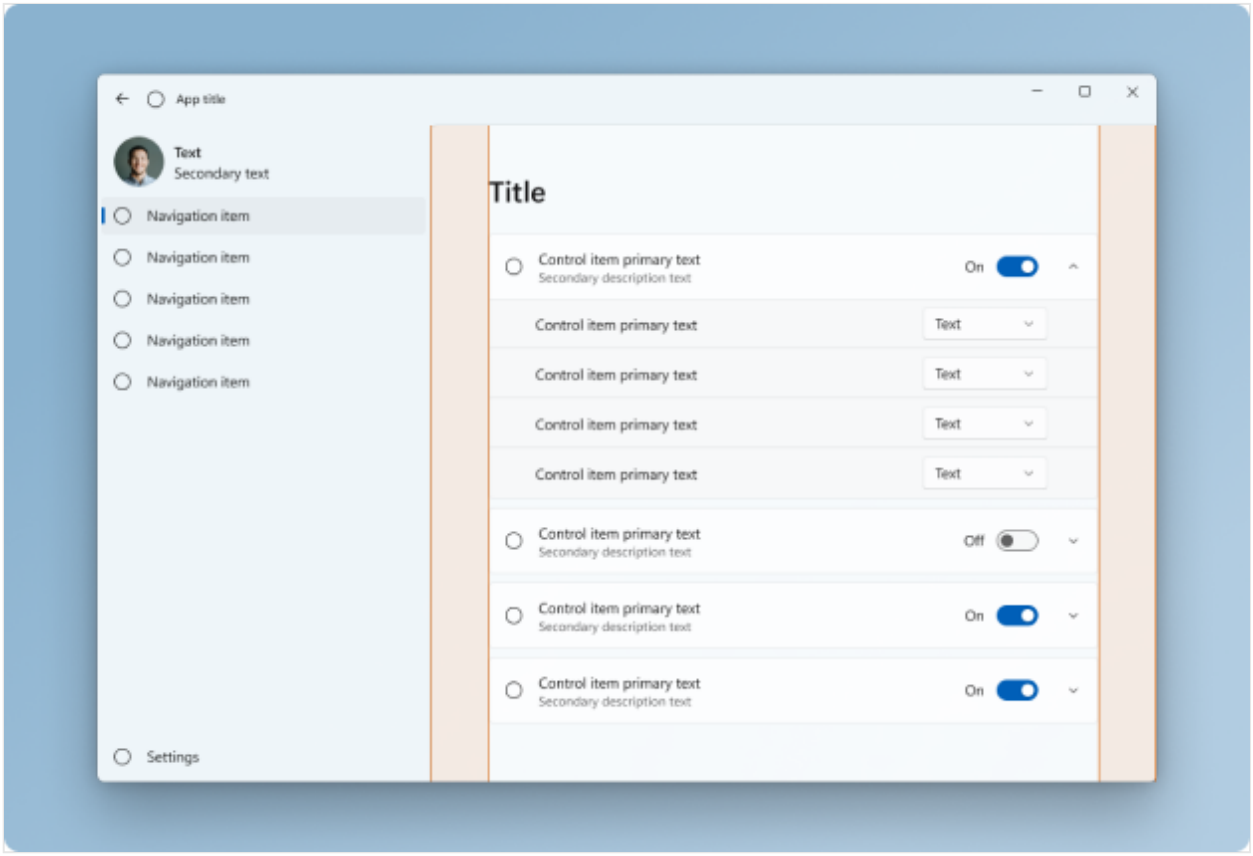
Design basics for Windows apps

Article • 10/04/2021

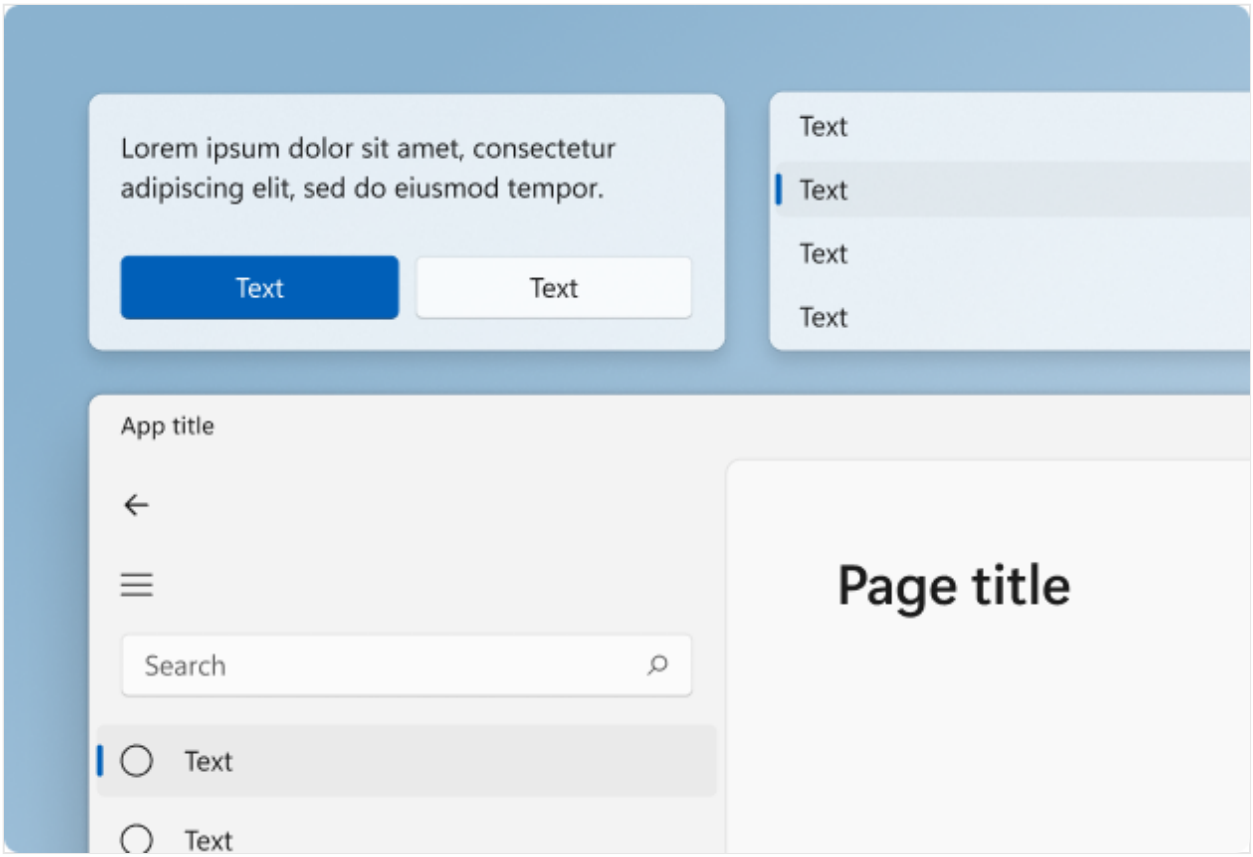
Windows design guidance is a resource to help you design and build beautiful, polished apps. It's not a list of prescriptive rules - it's a living document, designed to adapt to our evolving design language as well as the needs of our app-building community.

Overview



App Silhouette

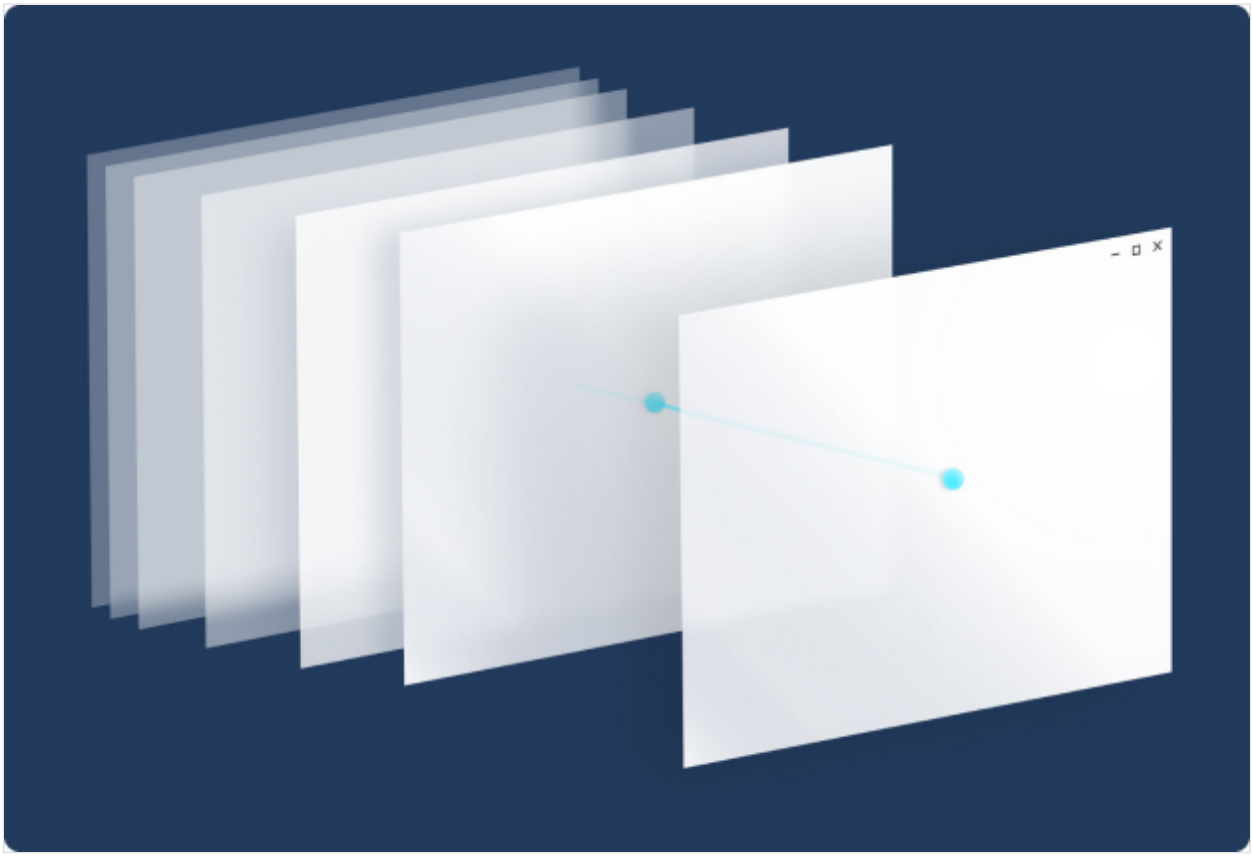
A high-level look at app patterns commonly used across our in-box applications.



Windows 11 Signature Experiences

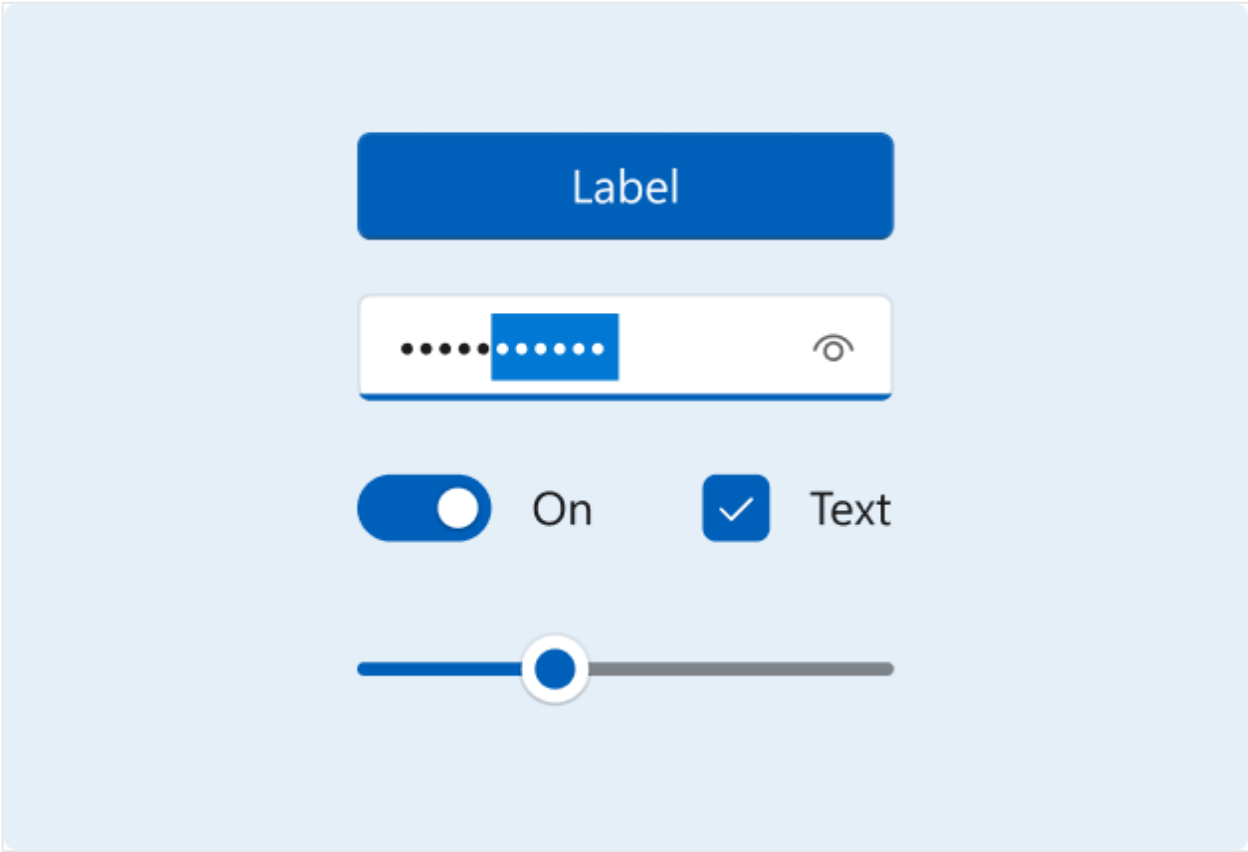
See what's new for Windows 11 design elements.

Basics



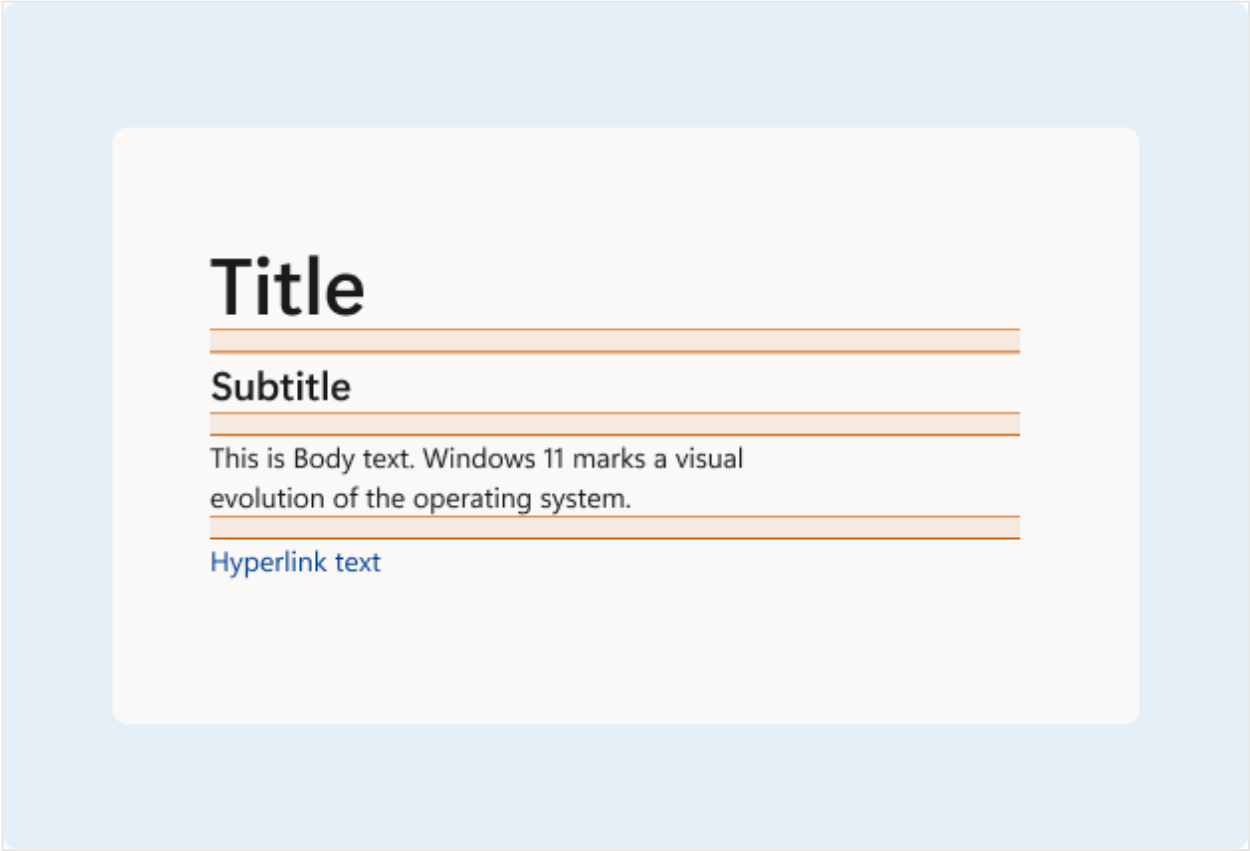
Navigation basics

Navigation in Windows apps is based on a flexible model of navigation structures, navigation elements, and system-level features. This article introduces you to these components and shows you how to use them together to create a good navigation experience.



Command basics

Command elements are the interactive UI elements that enable the user to perform actions, such as sending an email, deleting an item, or submitting a form. This article describes the command elements, such as buttons and check boxes, the interactions they support, and the command surfaces (such as command bars and context menus) for hosting them.



Content basics

This article provides some practical tips and examples to help you design the content of your app: Windows spacing rationale, using the type ramp to demonstrate hierarchy, lists and grids, and how to group controls.

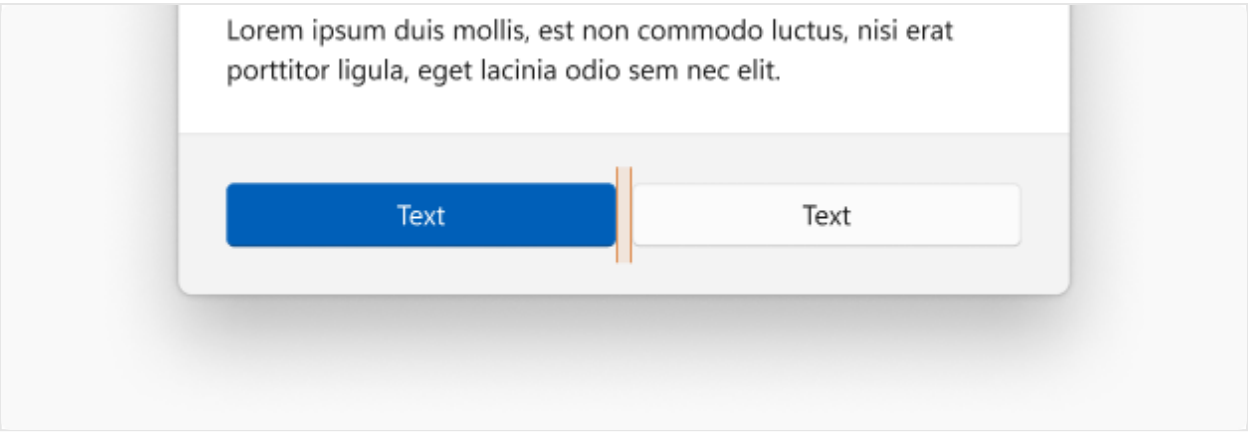
Content design basics for Windows apps

Article • 10/04/2021

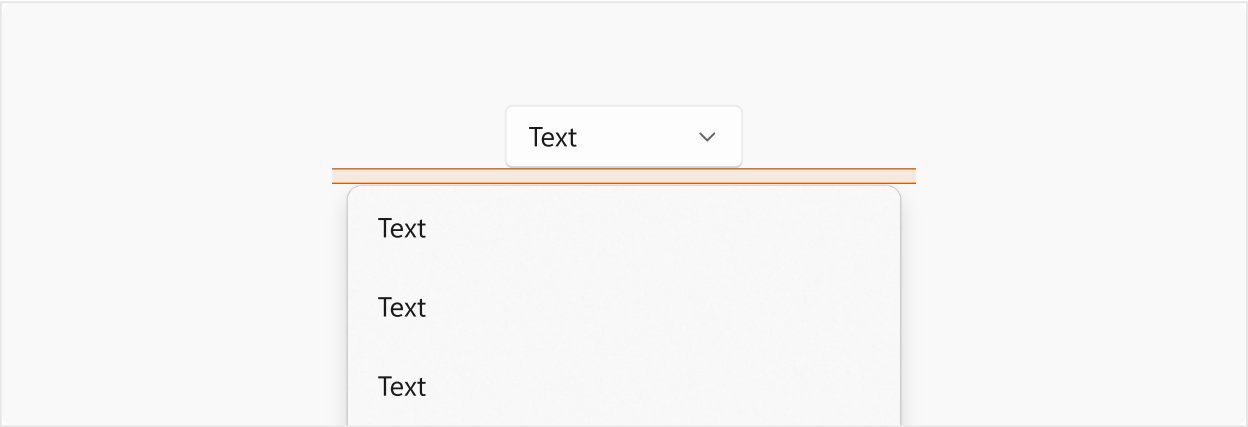
This article provides some practical tips and examples to help you design the content of your app: Windows spacing rationale, using the type ramp to demonstrate hierarchy, lists and grids, and how to group controls.

Spacing and gutters

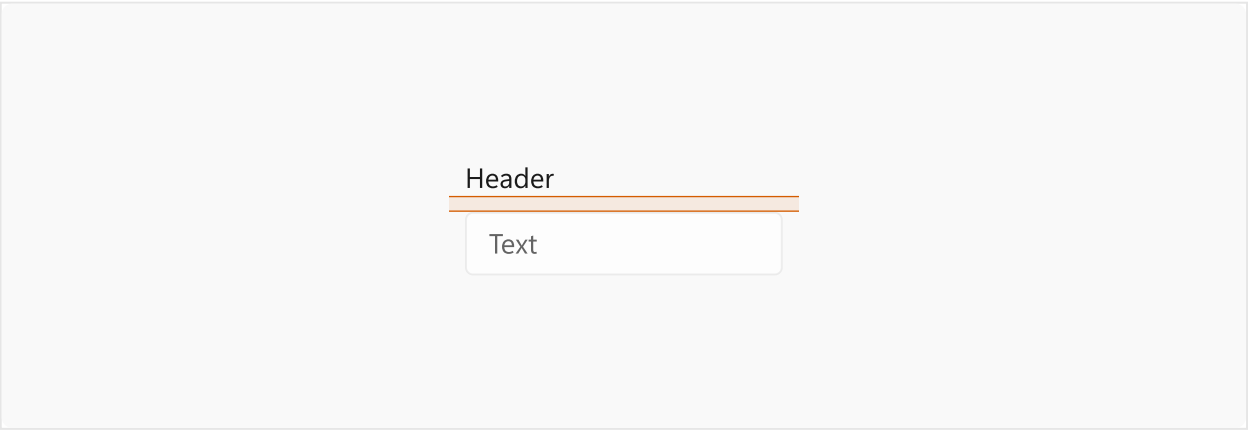
The use of consistently sized spacing and gutters semantically groups an experience into separate components. These values map to our rounded corner logic and together help create a cohesive and usable layout.



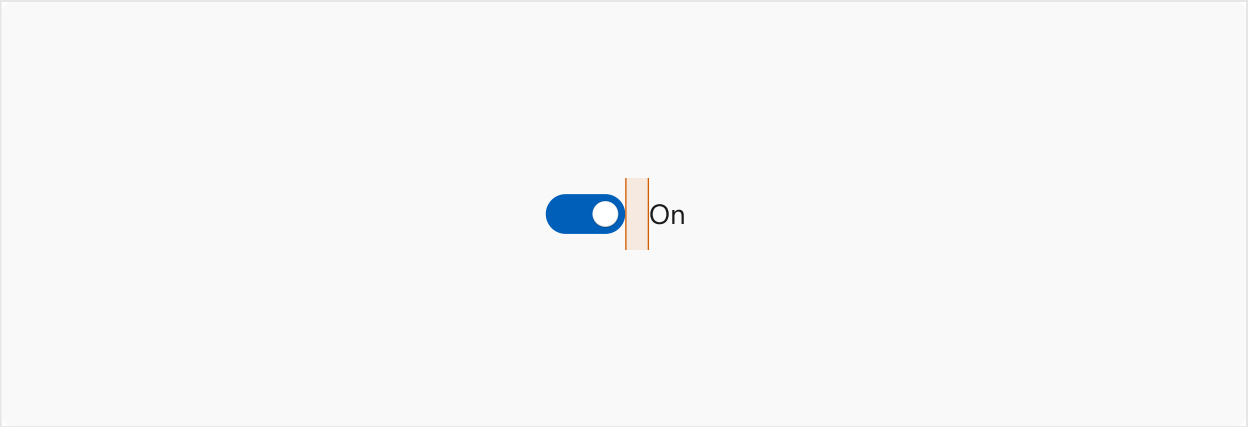
8epx between buttons



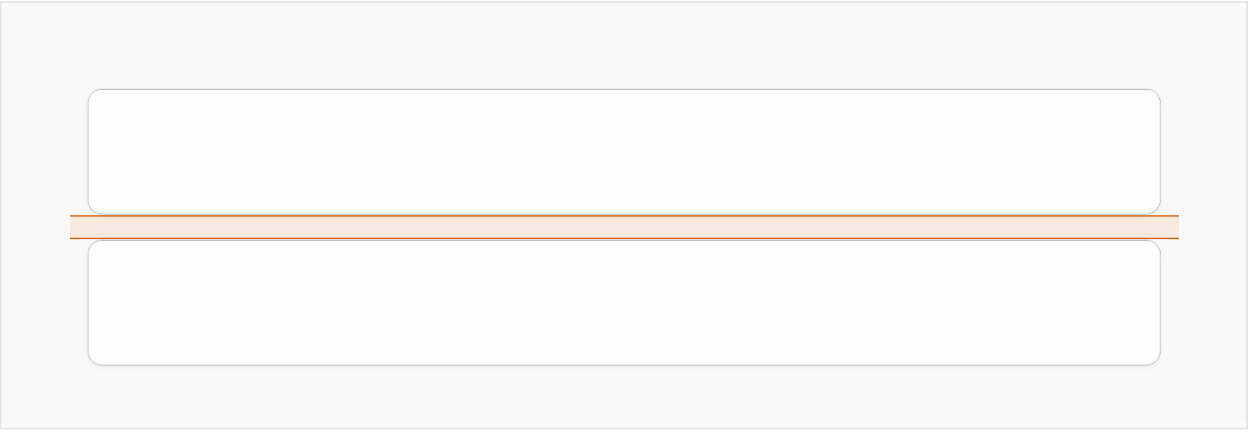
8epx between buttons and flyouts



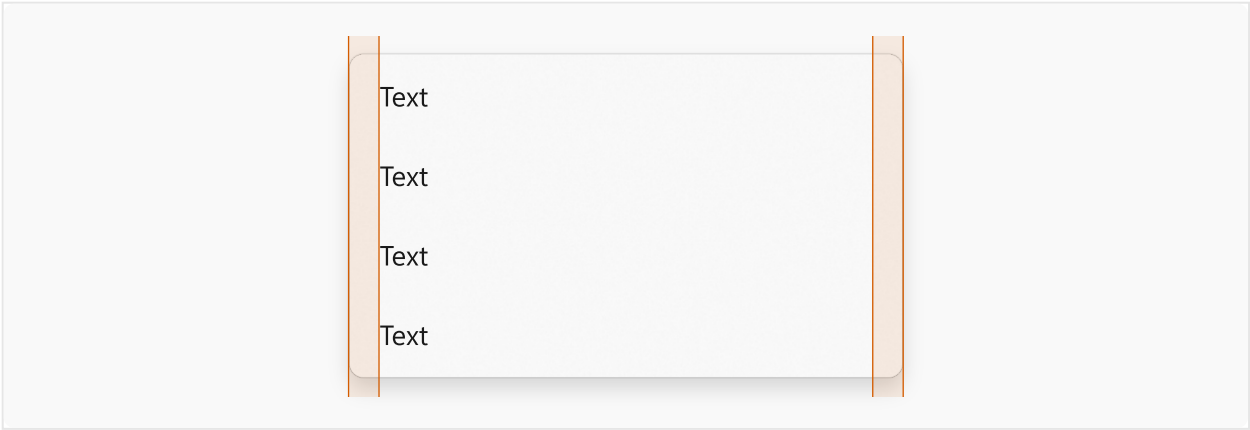
8epx between control and header



12epx between control and label



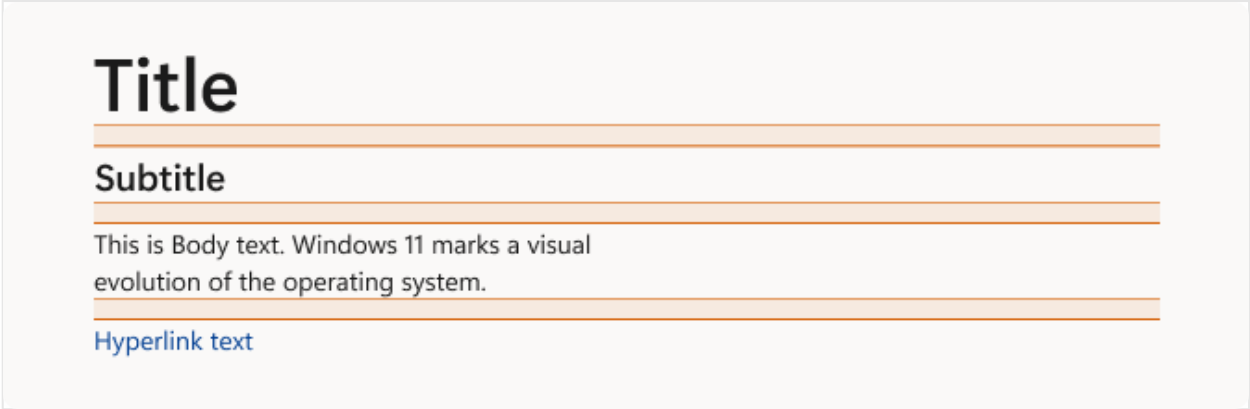
12epx between content areas



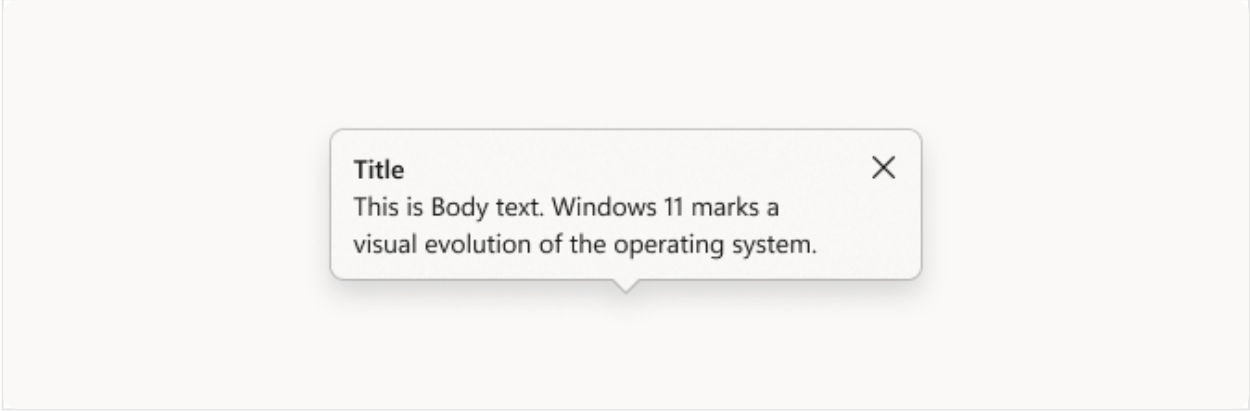
16epx between surface and edge text

Text + hierarchy

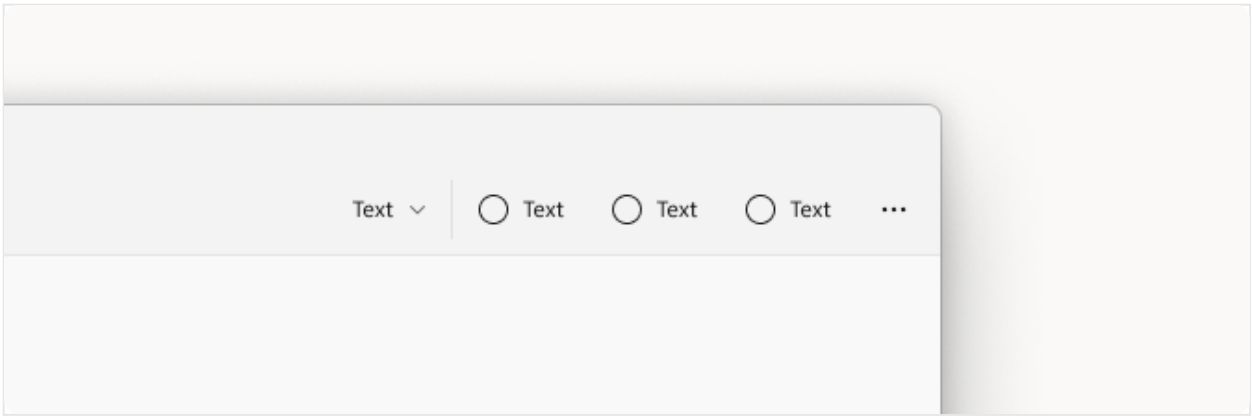
Our type ramp (link) is designed to provide an array of sizes that can help communicate hierarchy within an app.



Using Title, Subtitle and Body with 12epx spacing.



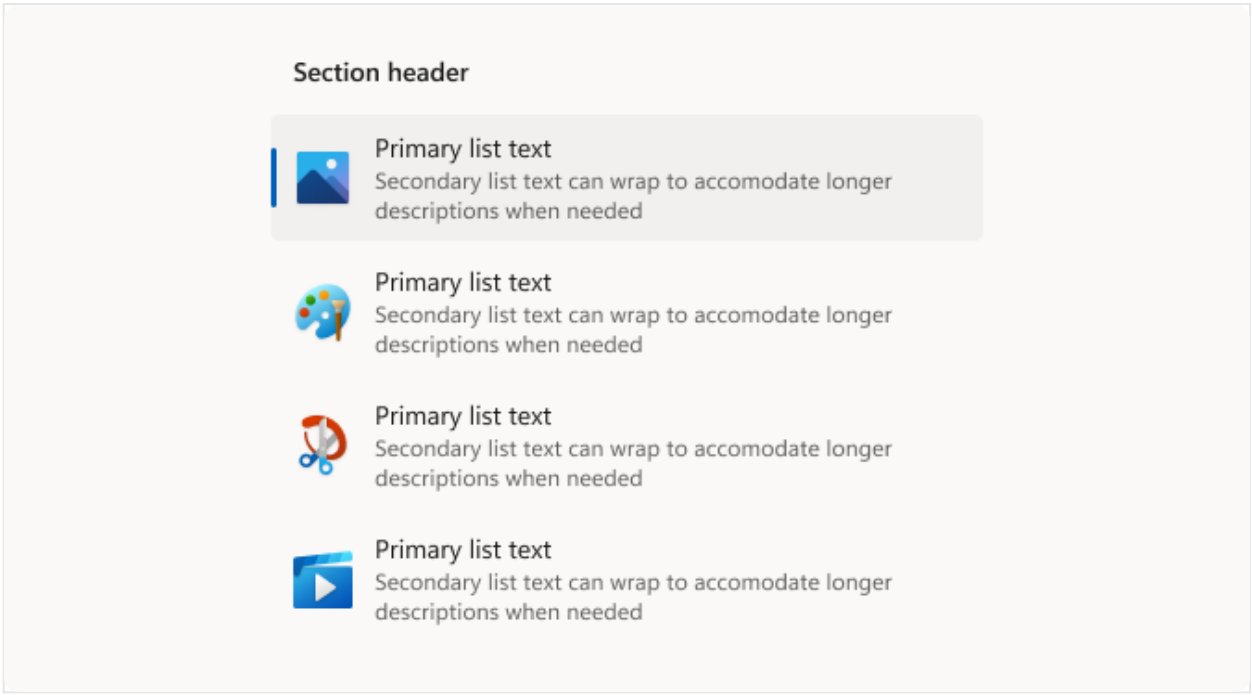
When differentiating a title in a confined UI space, use Body Strong for the title without any additional spacing between text blocks.



Use caption size for very confined spaces where text is needed, such as command buttons.

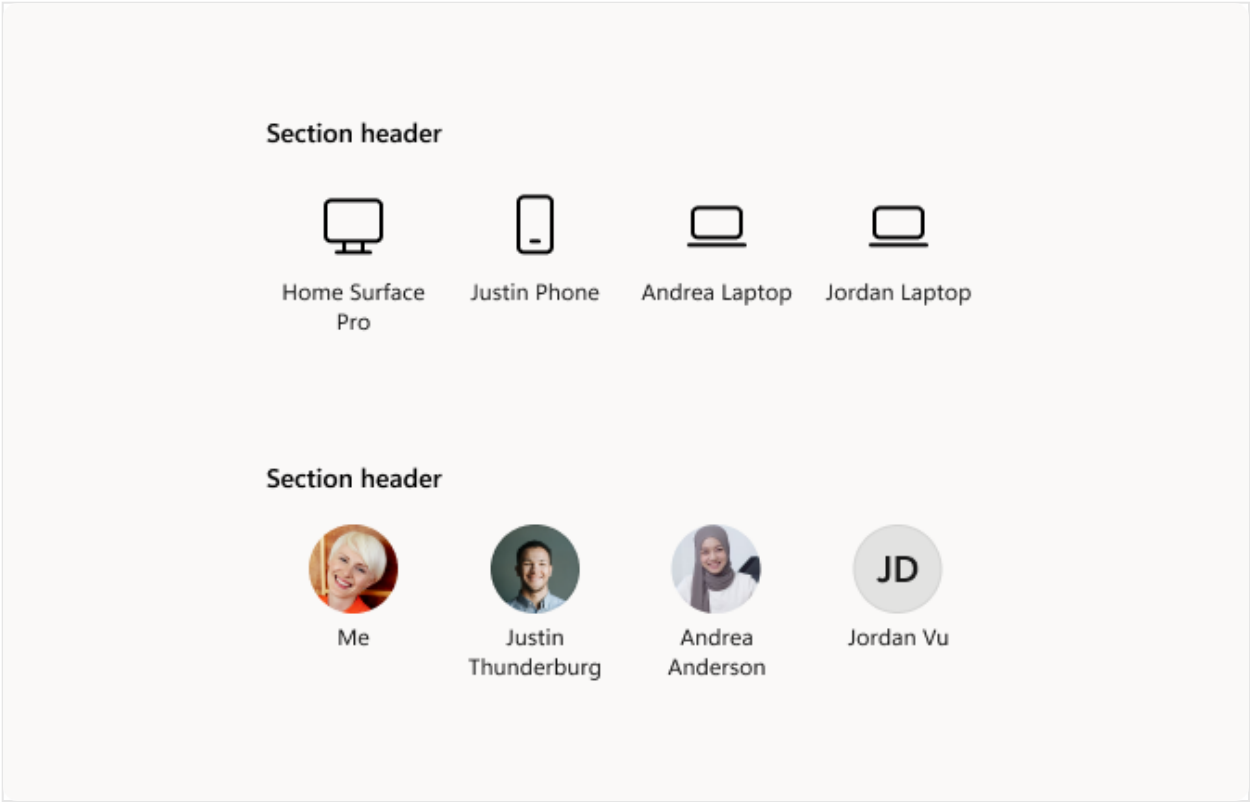
Lists and grids

There are a variety of list and grid styles that can be created. Below are a variety of compositions used in Windows.

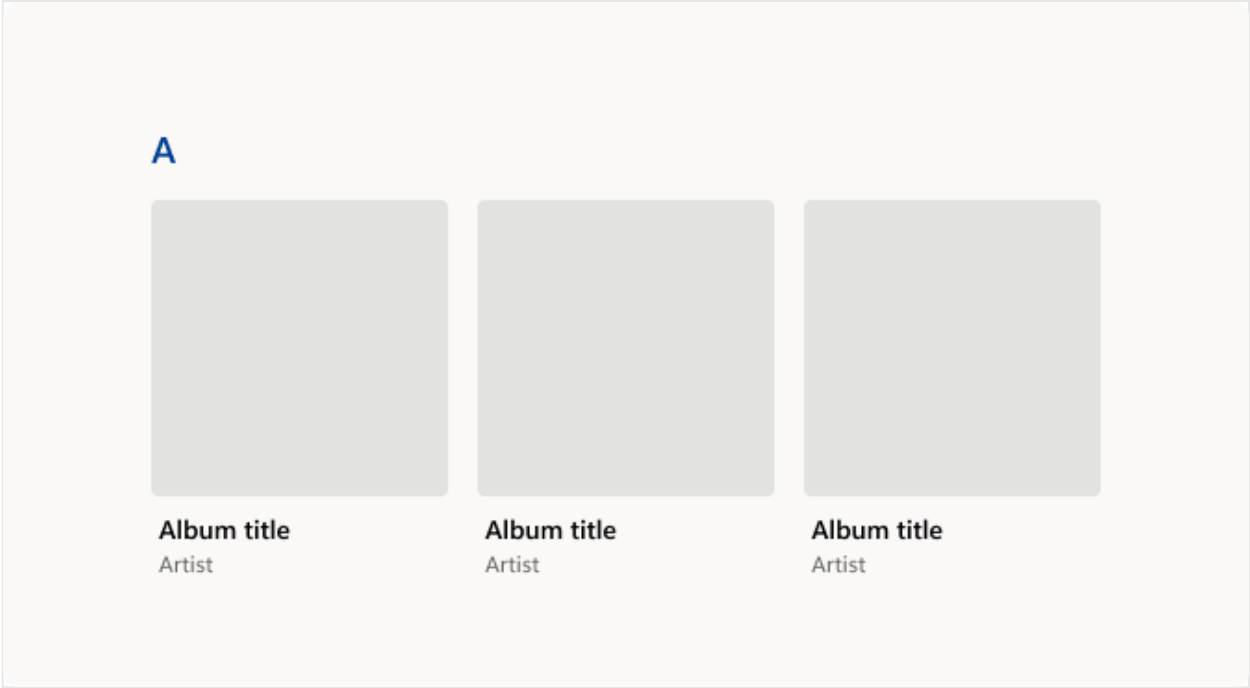


For multi-line lists, use Body and Caption from the type ramp, and 32epx icons.

Use Body Strong for section headers.



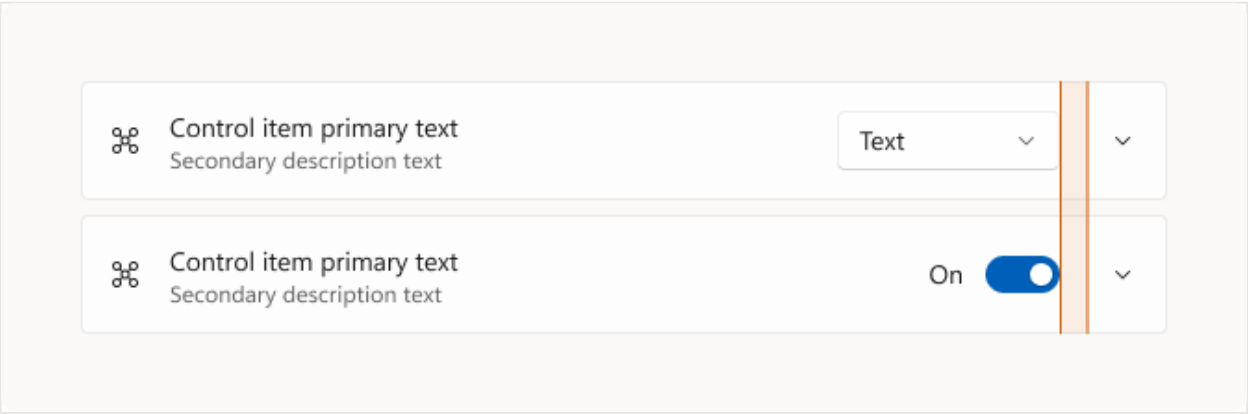
When using icons or person picture elements for grid items, use Caption text that is center-aligned.



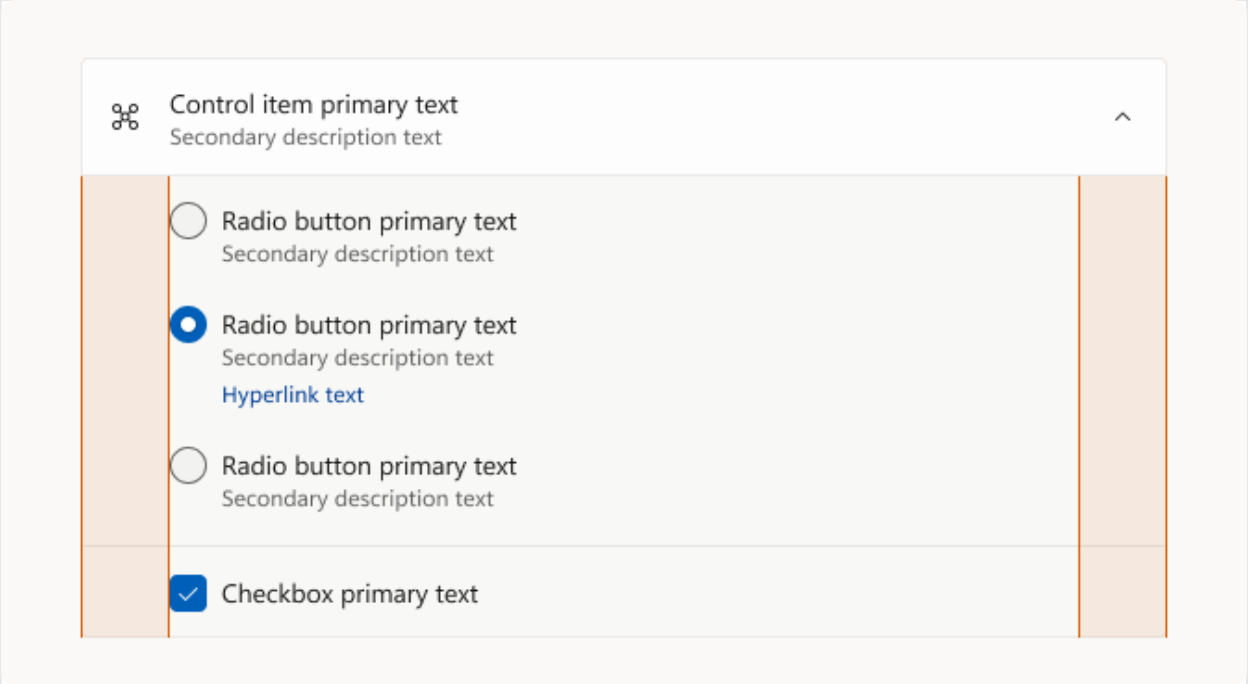
Use Body style for primary text and left-align to the image if your list contains large graphical elements with text.

Using controls

Some examples of how controls can relate to each other in common configurations.



Examples showing how to use an expander control (link) with list styles and common controls. Controls should be right-aligned with 16epx between the control and expander button.



This example shows controls alignment when placed inside the expander. Indent the controls 48epx.

Writing style

Article • 06/24/2021

The way you phrase an error message, the way you write help documentation, and even the text you choose for a button have big impacts on the usability of your app. Writing style can make a big difference between an awful user experience and a better one.

Voice and tone principles

Research shows that people respond best to a writing style that's friendly, helpful, and concise. As a part of this research, Microsoft developed three voice and tone principles that we apply across all our content, and are an integral part of Fluent design.

Be warm and relaxed

Above all else, you don't want to scare off the user. Be informal, be casual, and don't use terms they won't understand. Even when things break, don't blame the user for any problems. Your app should take responsibility instead, and offer welcoming guidance that puts the user's actions first.

Be ready to lend a hand

Always show empathy in your writing. Be focused on explaining what's going on and providing the information that the user needs, without overloading them with unnecessary info. And if possible, always provide a solution when there's a problem.

Be crisp and clear

Most of the time, text isn't the focus of an app. It's there to guide people, to teach them what's going on and what they should do next. Don't lose sight of this when writing the text in your app, and don't assume that users will read every word. Use language that is familiar to your audience, make sure it's easy to understand at a glance.

Lead with what's important

Users need to be able to read and understand your text at a glance. Don't pad your words with unnecessary introductions. Give your key points the most visibility, and always present the core of an idea before you add onto it.

✓ Do Select **filters** to add effects to your image.

✕ Don't If you want to add visual effects or alterations to your image, select **filters.**

Emphasize action

Apps are defined by actions. Users take action when they use the app, and the app takes action when it responds to the user. Make sure your text uses the *active voice* throughout your app. People and functions should be described as doing things, instead of having things done to them.

✓ Do Restart the app to see your changes.

✕ Don't The changes will be applied when the app is restarted.

Short and sweet

Users scan text, and will often skip over larger blocks of words entirely. Don't sacrifice necessary information and presentation, but don't use more words than you have to.

Sometimes, this will mean relying on many shorter sentences or fragments. Other times, this will mean being extra choosy about the words and structure of longer sentences.

✔ **Do** We couldn't upload the picture. If this happens again, try restarting the app. But don't worry — your picture will be waiting when you come back.

✘ **Don't** An error occurred, and we weren't able to upload the picture. Please try again, and if you encounter this problem again, you may need to restart the app. But don't worry — we've saved your work locally, and it'll be waiting for you when you come back.

Style conventions

If you don't consider yourself to be a writer, it can be intimidating to try to implement these principles and recommendations. But don't worry — using simple and straightforward language is a great way to provide a good user experience. And if you're still unsure how to structure your words, here are some helpful guidelines. And if you want more information, check out the Microsoft Style Guide.

Addressing the user

Speak directly to the user.

- Always address the user as "you."
- Use "we" to refer to your own perspective. It's welcoming and helps the user feel like part of the experience.
- Don't use "I" or "me" to refer to the app's perspective, even if you're the only one creating it.

✔ **Do** We couldn't save your file to that location.

Abbreviations

Abbreviations can be useful when you need to refer to products, places, or technical concepts multiple times throughout your app. They can save space and feel more natural, as long as the user understands them.

- Don't assume that users are already familiar with any abbreviations, even if you think they're common.
- Always define what a new abbreviation means the first time the user will see it.
- Don't use abbreviations that are too similar to one another.
- Don't use abbreviations if you're localizing your app, or if your users speak English as a second language.

✓ Do

The Windows app design guidance is a resource to help you design and build beautiful, polished apps. With the design features that are included in every Windows app, you can build user interfaces (UI) that scale across a range of devices.

Contractions

People are used to contractions, and expect to see them. Avoiding them can make your app seem too formal or even stilted.

- Use contractions when they're a natural fit for the text.
- Don't use unnatural contractions just to save space, or when they would make your words sound less conversational.

✓ Do

When you're happy with your image, select **save** to add it to your gallery. From there, you'll be able to share it with friends.

Periods

Ending text with a period implies that that text is a full sentence. Use a period for larger blocks of text, and avoid them for text that's shorter than a complete sentence.

- Use periods to end full sentences in tooltips, error messages, and dialogs.
- Don't end text for buttons, radio buttons, labels, or checkboxes with a period.

✓ Do

You're not connected.

- Check that your network cables are plugged in.
- Make sure you're not in airplane mode.
- See if your wireless switch is turned on.

- Restart your router.

Capitalization

While capital letters are important, they're easy to overuse.

- Capitalize proper nouns.
- Capitalize the start of every string of text in your app: the start of every sentence, label, and title.

✓ Do **Which part is giving you trouble?**

- I forgot your password.
- It won't accept password.
- Someone else might be using my account.

Error messages

When something goes wrong in your app, users pay attention. Because users might be confused or frustrated when they encounter an error message, they're an area where good voice and tone can have a particularly significant impact.

More than anything else, it's important that your error message doesn't blame the user. But it's also important not to overwhelm them with information that they don't understand. Most of the time a user who encounters an error just wants to get back to what they were doing as quickly and as easily as they can. Therefore, any error message you write should:

- **Be warm and relaxed** by using a conversational tone and avoiding unfamiliar terms and technical jargon.
- **Be ready to lend a hand** by telling the user what went wrong to the best of your ability, by telling them what will happen next, and by providing a realistic solution they can accomplish.
- **Be crisp and clear** by eliminating extraneous information.

✓ Do **You're not connected.**

- Check that your network cables are plugged in.

- Make sure you're not in airplane mode.
- See if your wireless switch is turned on.
- Restart your router.

Dialogs

Many of the same advice for writing error messages also applies when creating the text for any dialogs in your app. While dialogs are expected by the user, they still interrupt the normal flow of the app, and need to be helpful and concise so the user can get back to what they were doing.

But most important is the "call and response" between the title of a dialog and its buttons. Make sure that your buttons are clear answers to the question posed by the title, and that their format is consistent across your app.

✓ Do **Which part is giving you trouble?**

1. I forgot my password
2. It won't accept my password
3. Someone else might be using my account

Buttons

Text on buttons needs to be concise enough that users can read it all at a glance and clear enough that the button's function is immediately obvious. The longest the text on a button should ever be is a couple short words, and many should be shorter than that. When writing the text for buttons, remember that every button represents an action. Be sure to use the *active voice* in button text, to use words that represent actions rather than reactions.

✓ Do

- Install now
- Share

Spoken experiences

The same general principles and recommendations apply when writing text for spoken experiences, such as Cortana. In those features, the principles of good writing are even

more important, because you are unable to provide users with other visual design elements to supplement the spoken words.

- **Be warm and relaxed** by engaging your users with a conversational tone. More than in any other area, it's vital that a spoken experience sound warm and approachable, and be something that users aren't afraid to talk to.
- **Be ready to lend a hand** by providing alternative suggestions when the user asks the impossible. Much like in an error message, if something went wrong and your app isn't able to fulfill the request, it should give the user a realistic alternative that they can try asking, instead.
- **Be crisp and clear** by keeping your language simple. Spoken experiences aren't suitable for long sentences or complicated words.

Accessibility and localization

Your app can reach a wider audience if it's written with accessibility and localization in mind. This is something that can't only be accomplished through text, though straightforward and friendly language is a great start. For more information, see our accessibility overview and localization guidelines.

- **Be ready to lend a hand** by taking different experiences into account. Avoid phrases that might not make sense to an international audience, and don't use words that make assumptions about what the user can and can't do.
- **Be crisp and clear** by avoiding unusual and specialized words when they aren't necessary. The more straightforward your text is, the easier it is to localize.

Techniques for non-writers

You don't need to be a trained or experienced writer to provide your users with a good experience. Pick words that sound comfortable to you — they'll feel comfortable to others, too. But sometimes, that's not as easy as it sounds. If you get stuck, these techniques can help you out.

- Imagine that you're talking to a friend about your app. How would you explain the app to them? How would you talk about its features or give them instructions? Better yet, explain the app to an actual person who hasn't used it yet.
- Imagine how you would describe a completely different app. For instance, if you're making a game, think of what you'd say or write to describe a financial or a news

app. The contrast in the language and structure you use can give you more insight into the right words for what you're actually writing about.

- Take a look at similar apps for inspiration.

Finding the right words is a problem that many people struggle with, so don't feel bad if it's not easy to settle on something that feels natural.

Commanding basics

Article • 08/01/2022

In a Windows app, *command elements* are interactive UI elements that let users perform actions such as sending an email, deleting an item, or submitting a form. *Command interfaces* are composed of common command elements, the command surfaces that host them, the interactions they support, and the experiences they provide.

Provide the best command experience

The most important aspect of a command interface is what you're trying to let a user accomplish. As you plan the functionality of your app, consider the steps required to accomplish those tasks and the user experiences you want to enable. Once you've completed an initial draft of these experiences, then you can make decisions on the tools and interactions to implement them.

Here are some common command experiences:

- Sending or submitting information
- Selecting settings and choices
- Searching and filtering content
- Opening, saving, and deleting files
- Editing or creating content

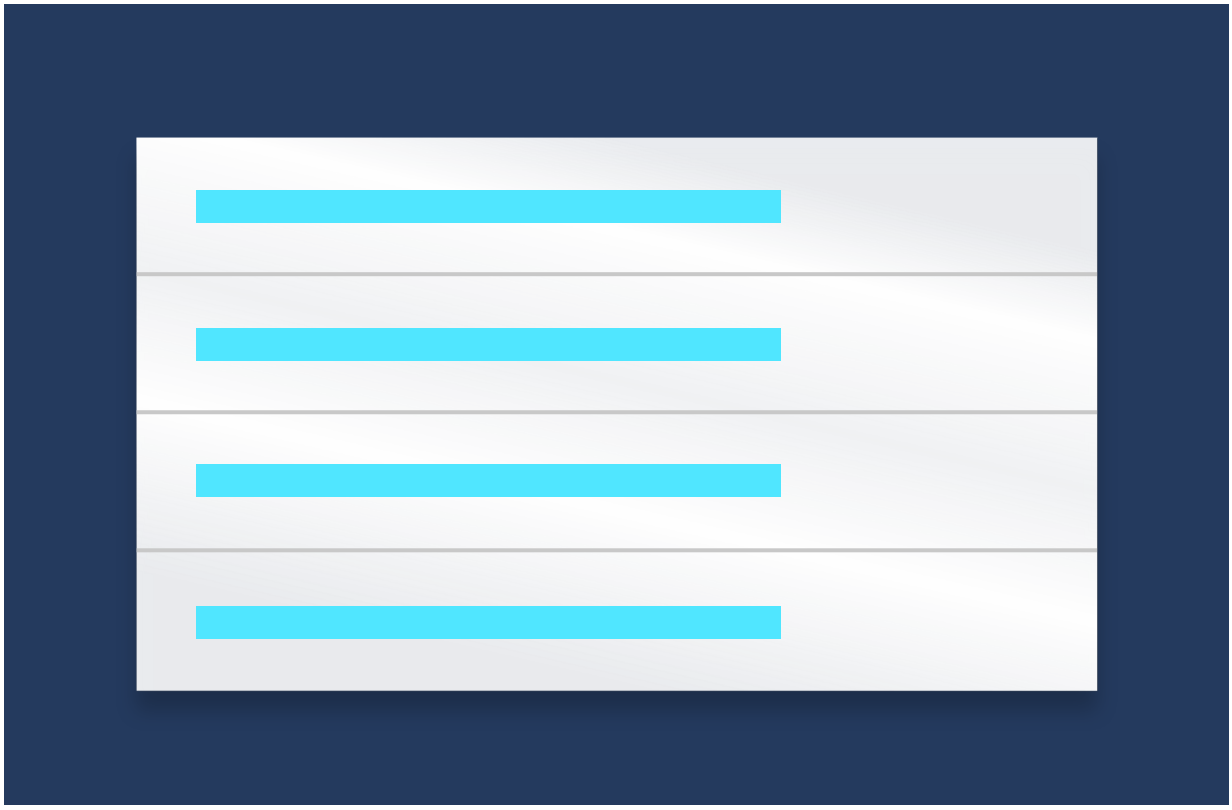
Be creative with the design of your command experiences. Choose which input devices your app supports, and how your app responds to each device. By supporting the broadest range of capabilities and preferences you make your app as usable, portable, and accessible as possible (see Commanding design for Windows apps for more detail).

Choose the right command elements

Using the right elements in a command interface can make the difference between an intuitive, easy-to-use app and a difficult, confusing app. A comprehensive set of command elements are available in the Windows app. Here's a list of some of the most common UWP command elements.

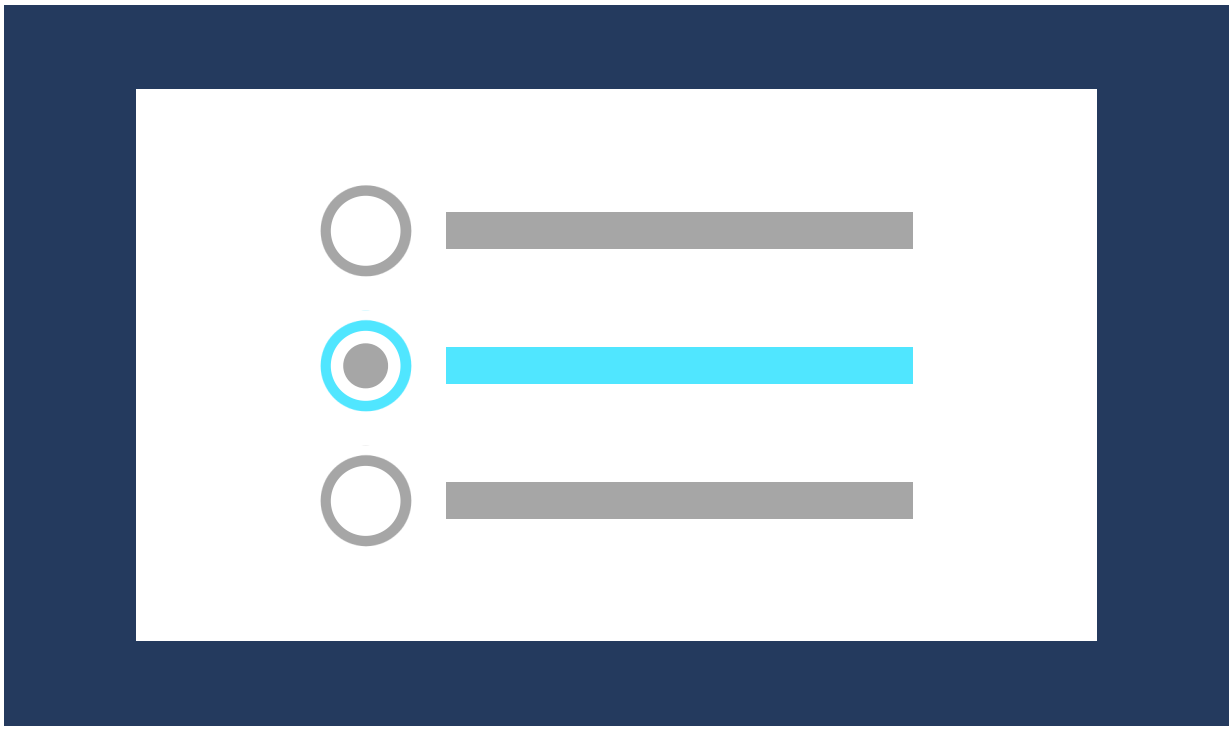
Buttons

Buttons trigger an immediate action. Examples include sending an email, submitting form data, or confirming an action in a dialog.



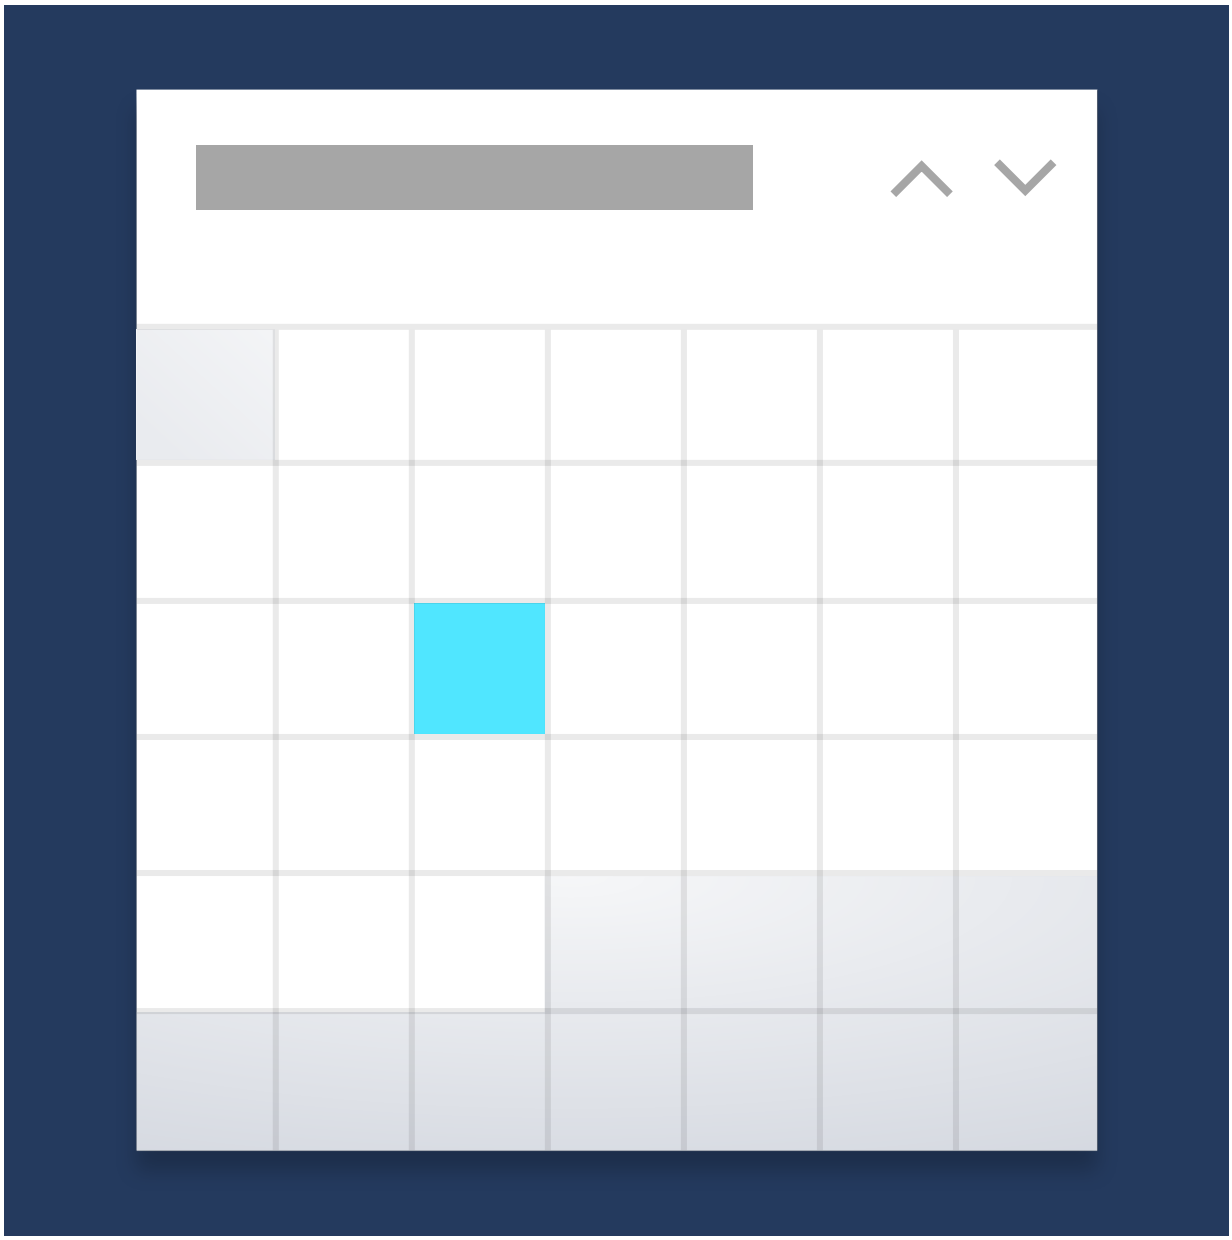
Lists

Lists present items in an interactive list or a grid. Usually used for many options or display items. Examples include drop-down list, list box, list view and grid view.



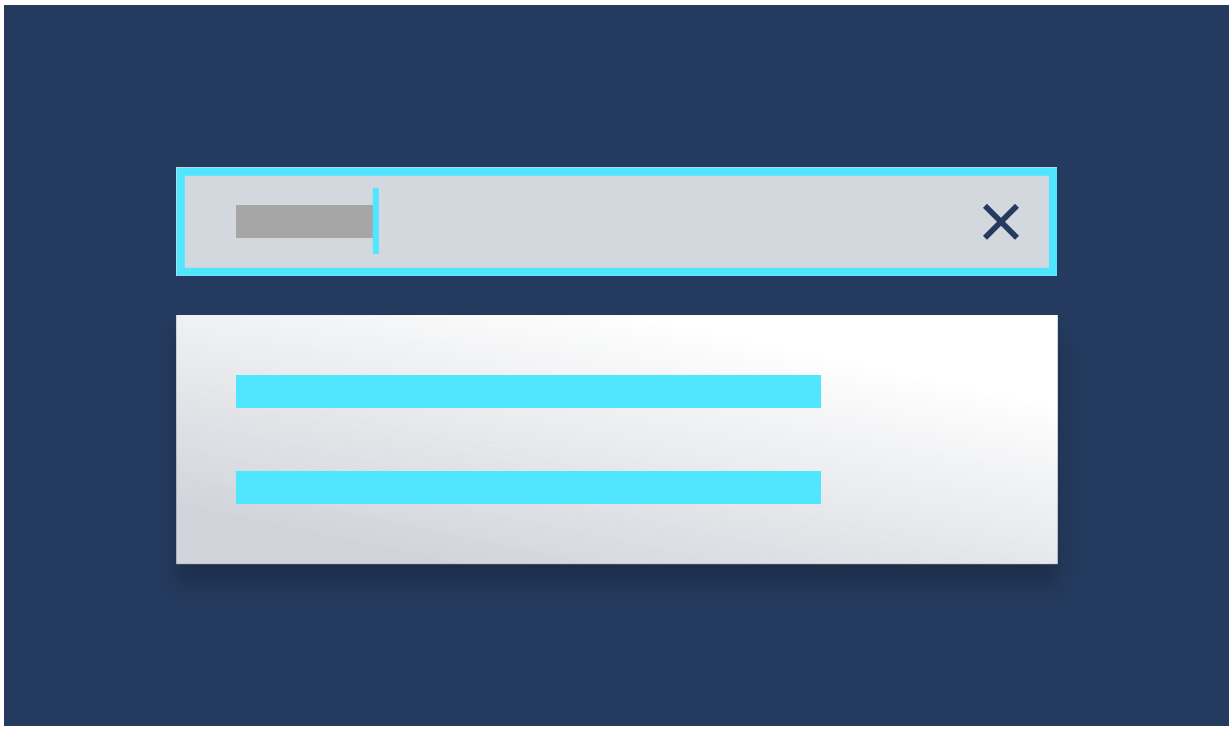
Selection controls

Lets users choose from a few options, such as when completing a survey or configuring app settings. Examples include CheckBox, RadioButton, and Toggle switch.



Calendar, date and time pickers

Calendar, date and time pickers enable users to view and modify date and time info, such as when creating an event or setting an alarm. Examples include calendar date picker, calendar view, date picker, time picker.



Predictive text entry

Provides suggestions as users type, such as when entering data or performing queries. Examples include AutoSuggestBox.

For a complete list, see Controls and UI elements

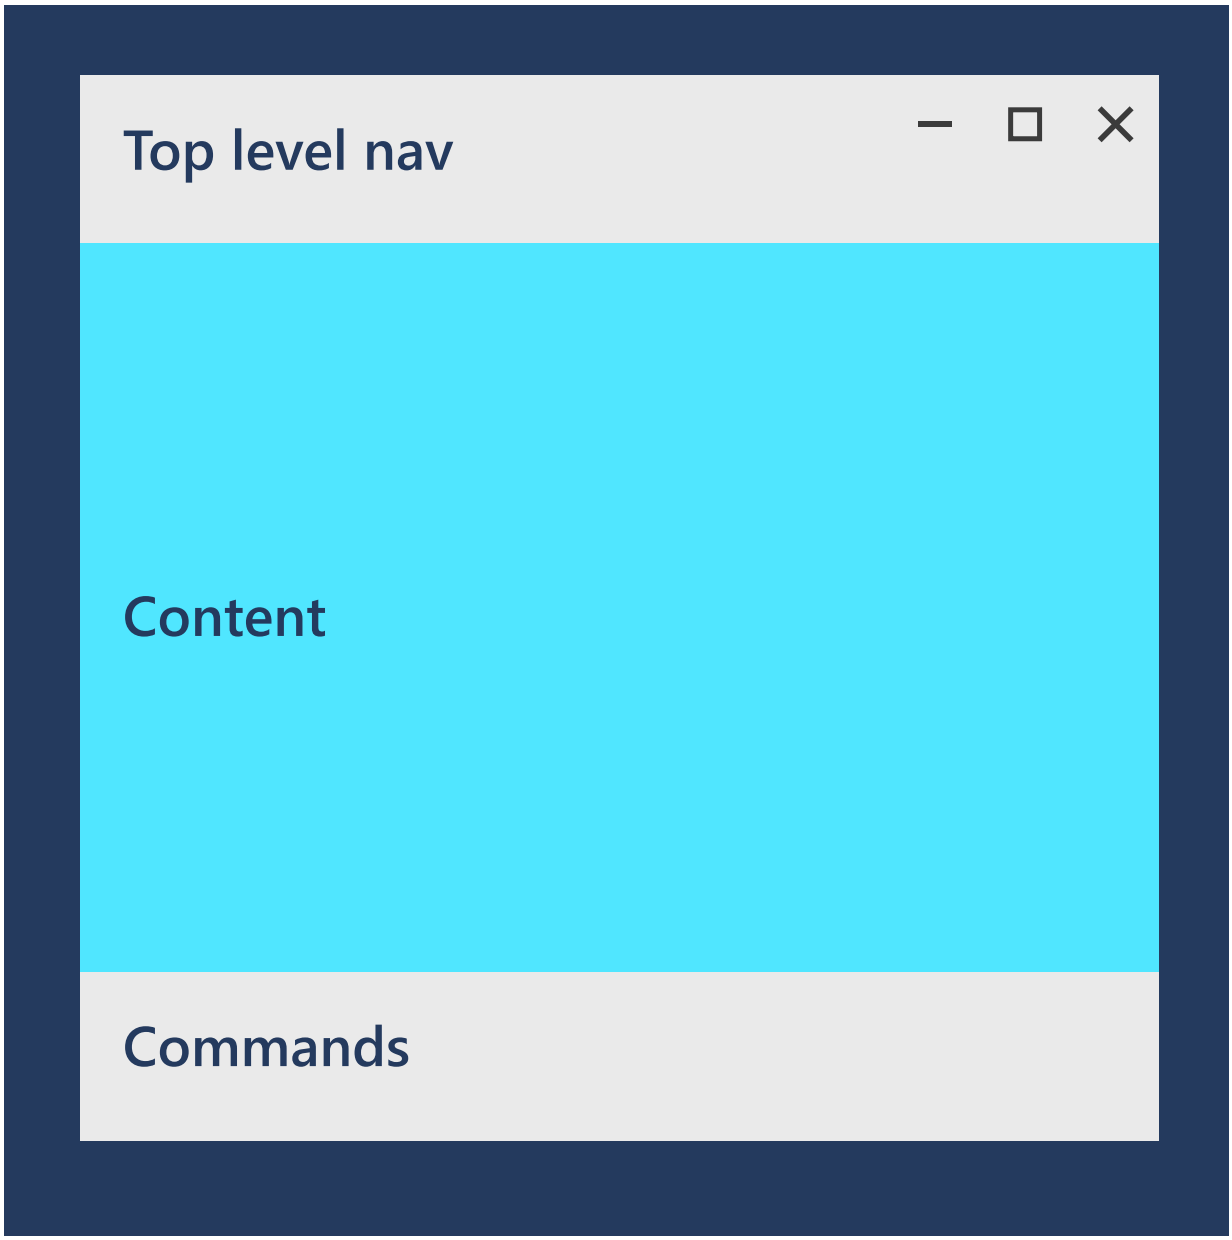
Place commands on the right surface

You can place command elements on a number of surfaces in your app, including the app canvas or special command containers, such as a command bar, command bar flyout, menu bar, or dialog.

Always try to let users manipulate content directly rather than through commands that act on the content, such as dragging and dropping to rearrange list items rather than up and down command buttons.

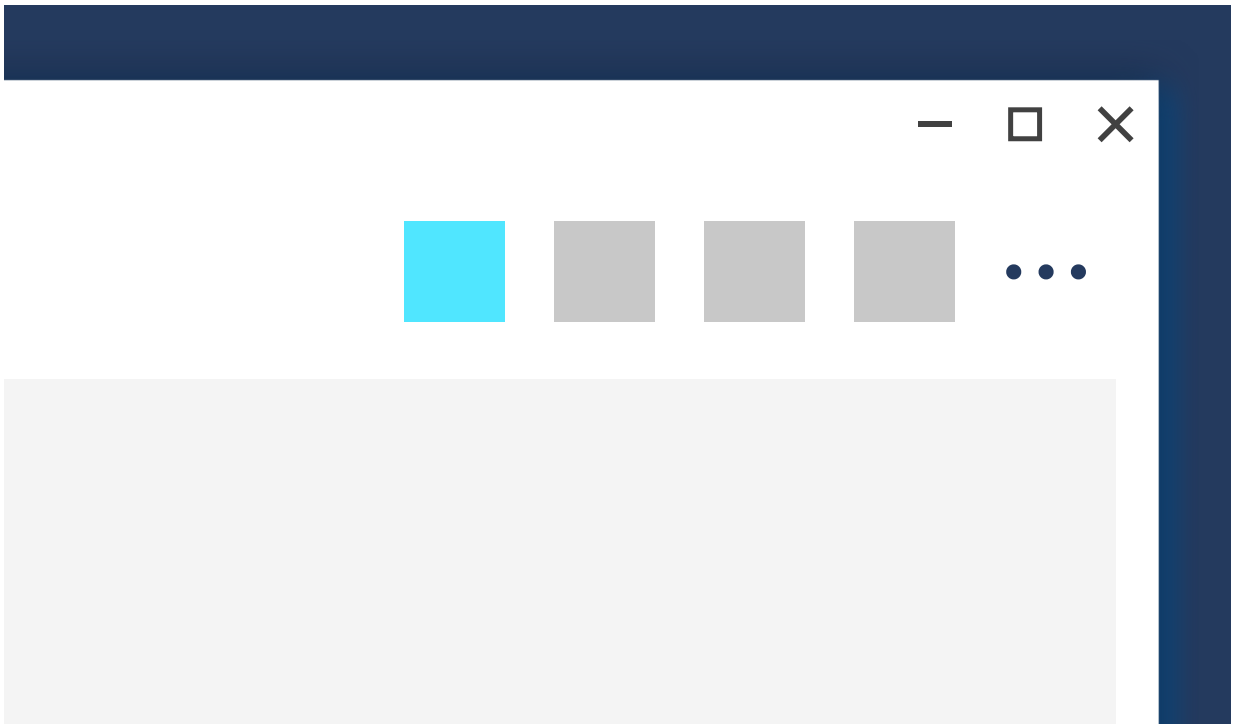
However, this might not be possible with certain input devices, or when accommodating specific user abilities and preferences. In these cases, provide as many commanding affordances as possible, and place these command elements on a command surface in your app.

Here's a list of some of the most common command surfaces.



App canvas (content area)

If a command is constantly needed for users to complete core scenarios, put it on the canvas. Because you can put commands near (or on) the objects they affect, putting commands on the canvas makes them easy and obvious to use. However, choose the commands you put on the canvas carefully. Too many commands on the app canvas take up valuable screen space and can overwhelm the user. If the command won't be frequently used, consider putting it in another command surface.



Command bars and menu bars

Command bars help organize commands and make them easy to access. Command bars can be placed at the top of the screen, at the bottom of the screen, or at both the top and bottom of the screen (a MenuBar can also be used when the functionality in your app is too complex for a command bar).

Menus and context menus

Menus and context menus save space by organizing commands and hiding them until the user needs them. Users typically access a menu or context menu by clicking a button or right-clicking a control.

The CommandBarFlyout is a type of contextual menu that combines the benefits of a command bar and a context menu into a single control. It can provide shortcuts to commonly-used actions and provide access to secondary commands that are only relevant in certain contexts, such as clipboard or custom commands.

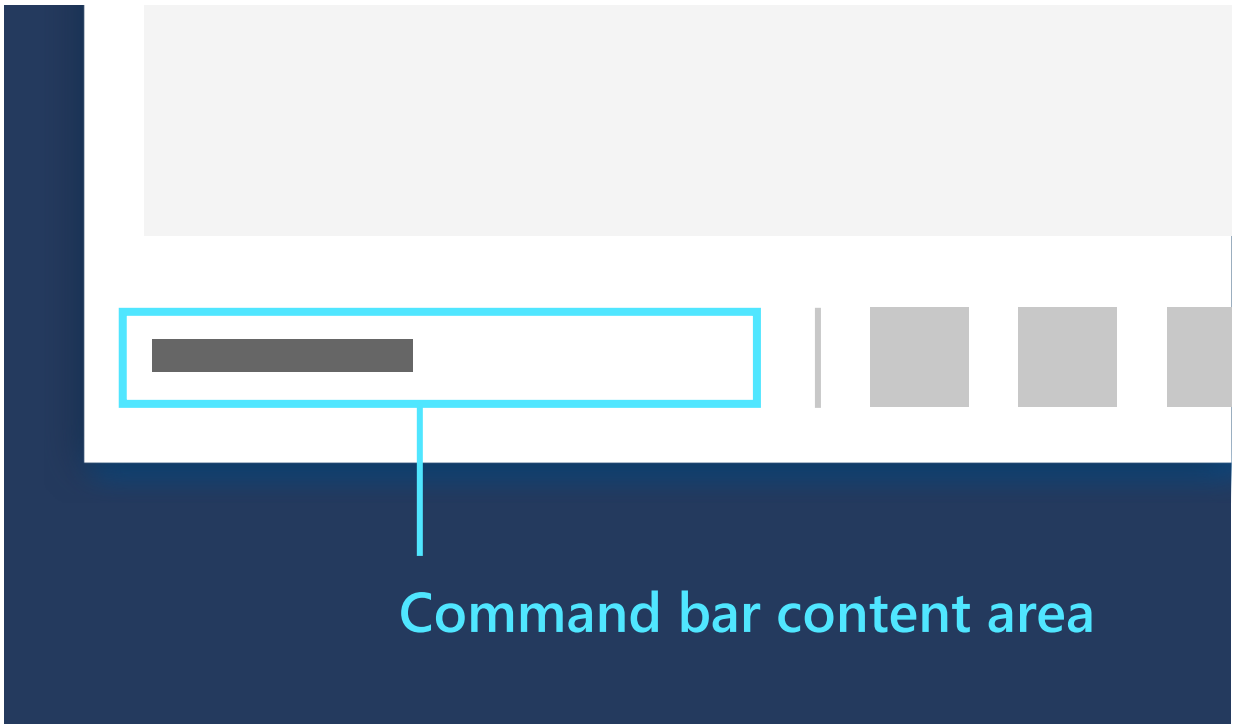
UWP also provides a set of traditional menus and context menus; for more info, see Menus and context menus.

Provide command feedback

Command feedback communicates to users that an interaction or command was detected, how the command was interpreted and handled, and whether the command was successful or not. This helps users understand what they've done, and what they can do next. Ideally, feedback should be integrated naturally in your UI, so users don't have to be interrupted, or take additional action unless absolutely necessary.

> **Note**
>
> Provide feedback only when necessary and only if it's not available elsewhere. Keep your application UI clean and uncluttered unless you are adding value.

Here are some ways to provide feedback in your app.



Command bar

The content area of the CommandBar is an intuitive place to communicate status to users if they'd like to see feedback.

Flyouts

Flyouts are lightweight contextual popups that can be dismissed by tapping or clicking somewhere outside the flyout.

Dialog controls

Dialog controls are modal UI overlays that provide contextual app information. In most cases, dialogs block interactions with the app window until being explicitly dismissed, and often request some kind of action from the user. Dialogs can be disruptive and should only be used in certain situations. For more info, see the When to confirm or undo actions section.

> **Tip**
>
> Be careful of how much your app uses confirmation dialogs; they can be very helpful when the user makes a mistake, but they are a hindrance whenever the user is trying to perform an action intentionally.

When to confirm or undo actions

No matter how well-designed your application's UI is, all users perform an action they wish they hadn't. Your app can help in these situations by requiring confirmation of an action, or by providing a way to undo recent actions.

For actions that can't be undone and have major consequences, we recommend using a confirmation dialog. Examples of such actions include:

- Overwriting a file

- Not saving a file before closing
- Confirming permanent deletion of a file or data
- Making a purchase (unless the user opts out of requiring a confirmation)
- Submitting a form, such as signing up for something

For actions that can be undone, offering a simple undo command is usually enough. Examples of such actions include:

- Deleting a file
- Deleting an email (not permanently)
- Modifying content or editing text
- Renaming a file

Optimize for specific input types

See the Interaction primer for more detail on optimizing user experiences around a specific input type or device.

Sound

Article • 05/17/2022

There are many ways to use sound to enhance your app. You can use to sound to supplement other UI elements, enabling users to recognize events audibly. Sound can be an effective user interface element for people with visual disabilities. You can use sound to create an atmosphere that immerses the user; for example, you might play a whimsical soundtrack in the background of puzzle game, or use ominous sound effects for a horror/survival game.

Examples

WinUI 2 Gallery

If you have the **WinUI 2 Gallery** app installed, click here to open the app and see Sound in action.

- Get the WinUI 2 Gallery app (Microsoft Store)
- Get the source code (GitHub)

Sound Global API

UWP provides an easily accessible sound system that allows you to simply "flip a switch" and get an immersive audio experience across your entire app.

The **ElementSoundPlayer** is an integrated sound system within XAML, and when turned on all default controls will play sounds automatically.

C#

```
ElementSoundPlayer.State = ElementSoundPlayerState.On;
```

The **ElementSoundPlayer** has three different states: **On Off** and **Auto**.

If set to **Off**, no matter where your app is run, sound will never play. If set to **On** sounds for your app will play on every platform.

Enabling ElementSoundPlayer will automatically enable spatial audio (3D sound) as well. To disable 3D sound (while still keeping the sound on), disable the **SpatialAudioMode** of the ElementSoundPlayer:

C#

```
ElementSoundPlayer.SpatialAudioMode = ElementSpatialAudioMode.Off
```

The **SpatialAudioMode** property can takes these values:

- **Auto**: Spatial audio will turn on when sound is on.
- **Off**: Spatial audio is always off, even if sound is on.
- **On**: Spatial audio will always play.

To learn more about spatial audio and how XAML handles it see AudioGraph - Spatial Audio.

Sound for TV and Xbox

Sound is a key part of the 10-foot experience, and by default, the **ElementSoundPlayer**'s state is **Auto**, meaning that you will only get sound when your app is running on Xbox. Please see Designing for Xbox and TV for more details.

Sound Volume Override

All sounds within the app can be dimmed with the **Volume** control. However, sounds within the app cannot get *louder than the system volume*.

To set the app volume level, call:

C#

```
ElementSoundPlayer.Volume = 0.5;
```

Where maximum volume (relative to system volume) is 1.0, and minimum is 0.0 (essentially silent).

Control Level State

If a control's default sound is not desired, it can be disabled. This is done through the **ElementSoundMode** on the control.

The **ElementSoundMode** has two states: **Off** and **Default**. When not set, it is **Default**. If set to **Off**, every sound that control plays will be muted *except for focus*.

XAML

```
<Button Name="ButtonName" Content="More Info" ElementSoundMode="Off"/>
```

C#

```
ButtonName.ElementSoundState = ElementSoundMode.Off;
```

Is This The Right Sound?

When creating a custom control, or changing an existing control's sound, it is important to understand the usages of all the sounds the system provides.

Each sound relates to a certain basic user interaction, and although sounds can be customized to play on any interaction, this section serves to illustrate the scenarios where sounds should be used to maintain a consistent experience across all UWP apps.

Invoking an Element

The most common control-triggered sound in our system today is the **Invoke** sound. This sound plays when a user invokes a control through a tap/click/enter/space or press of the 'A' button on a gamepad.

Typically, this sound is only played when a user explicitly targets a simple control or control part through an input device.

To play this sound from any control event, simply call the Play method from **ElementSoundPlayer** and pass in **ElementSound.Invoke**:

C#

```
ElementSoundPlayer.Play(ElementSoundKind.Invoke);
```

Showing & Hiding Content

There are many flyouts, dialogs and dismissible UIs in XAML, and any action that triggers one of these overlays should call a **Show** or **Hide** sound.

When an overlay content window is brought into view, the **Show** sound should be called:

```
C#

ElementSoundPlayer.Play(ElementSoundKind.Show);
```

Conversely when an overlay content window is closed (or is light dismissed), the **Hide** sound should be called:

```
C#

ElementSoundPlayer.Play(ElementSoundKind.Hide);
```

Navigation Within a Page

When navigating between panels or views within an app's page (see NavigationView), there is typically bidirectional movement. Meaning you can move to the next view/panel or the previous one, without leaving the current app page you're on.

The audio experience around this navigation concept is encompassed by the **MovePrevious** and **MoveNext** sounds.

When moving to a view/panel that is considered the *next item* in a list, call:

```
C#

ElementSoundPlayer.Play(ElementSoundKind.MoveNext);
```

And when moving to a previous view/panel in a list considered the *previous item*, call:

```
C#

ElementSoundPlayer.Play(ElementSoundKind.MovePrevious);
```

Back Navigation

When navigating from the current page to the previous page within an app the **GoBack** sound should be called:

```
C#

ElementSoundPlayer.Play(ElementSoundKind.GoBack);
```

Focusing on an Element

The **Focus** sound is the only implicit sound in our system. Meaning a user isn't directly interacting with anything, but is still hearing a sound.

Focusing happens when a user navigates through an app, this can be with the gamepad/keyboard/remote or kinect. Typically the **Focus** sound *does not play on PointerEntered or mouse hover events*.

To set up a control to play the **Focus** sound when your control receives focus, call:

```
C#

ElementSoundPlayer.Play(ElementSoundKind.Focus);
```

Cycling Focus Sounds

As an added feature to calling **ElementSound.Focus**, the sound system will, by default, cycle through 4 different sounds on each navigation trigger. Meaning that no two exact focus sounds will play right after the other.

The purpose behind this cycling feature is to keep the focus sounds from becoming monotonous and from being noticeable by the user; focus sounds will be played most often and therefore should be the most subtle.

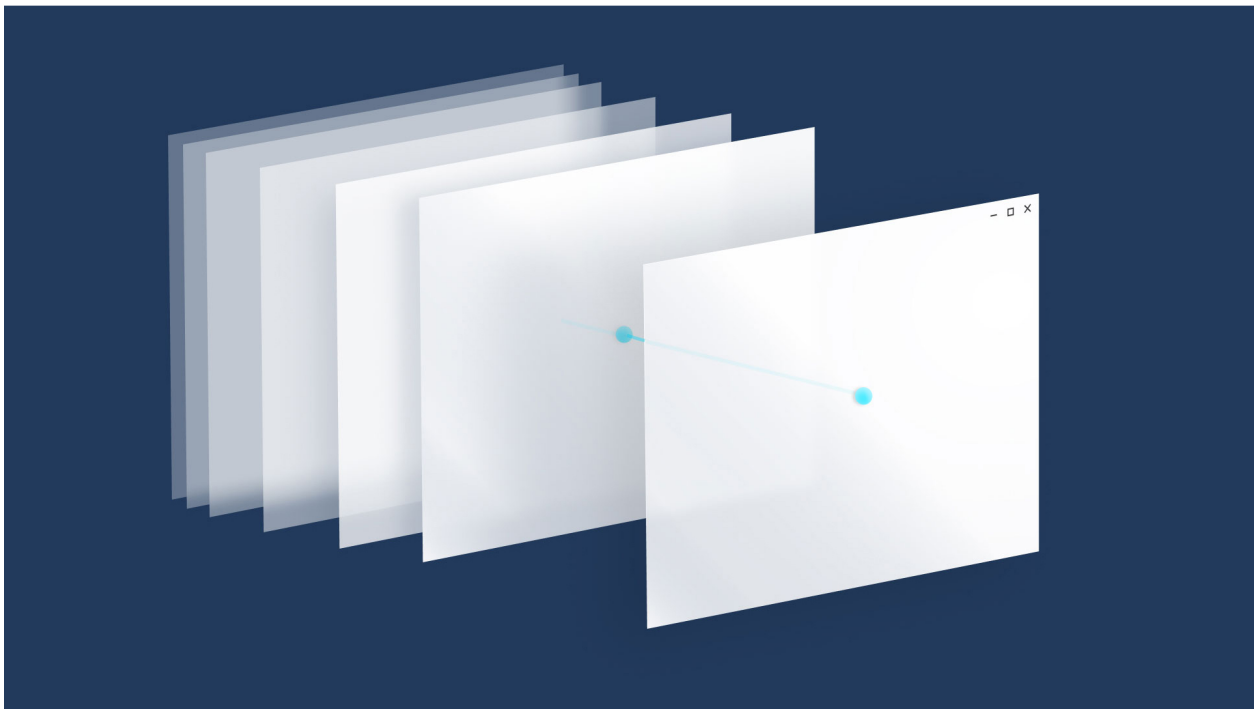
Navigation design basics for Windows apps

Article • 04/12/2023

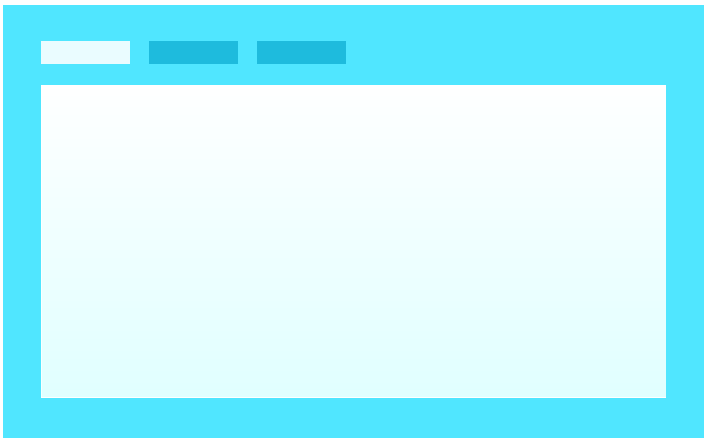


If you think of an app as a collection of pages, *navigation* describes the act of moving between pages and within a page. It's the starting point of the user experience, and it's how users find the content and features they're interested in. It's very important, and it can be difficult to get right.

You have a huge number of choices to make for navigation. You could:

Require users to go through a series of pages in order.

Provide a menu that allows users to jump directly to any page.



Place everything on a single page and provide filtering mechanisms for viewing content.

While there's no single navigation design that works for every app, there are principles and guidelines to help you decide the right design for your app.

Principles of good navigation

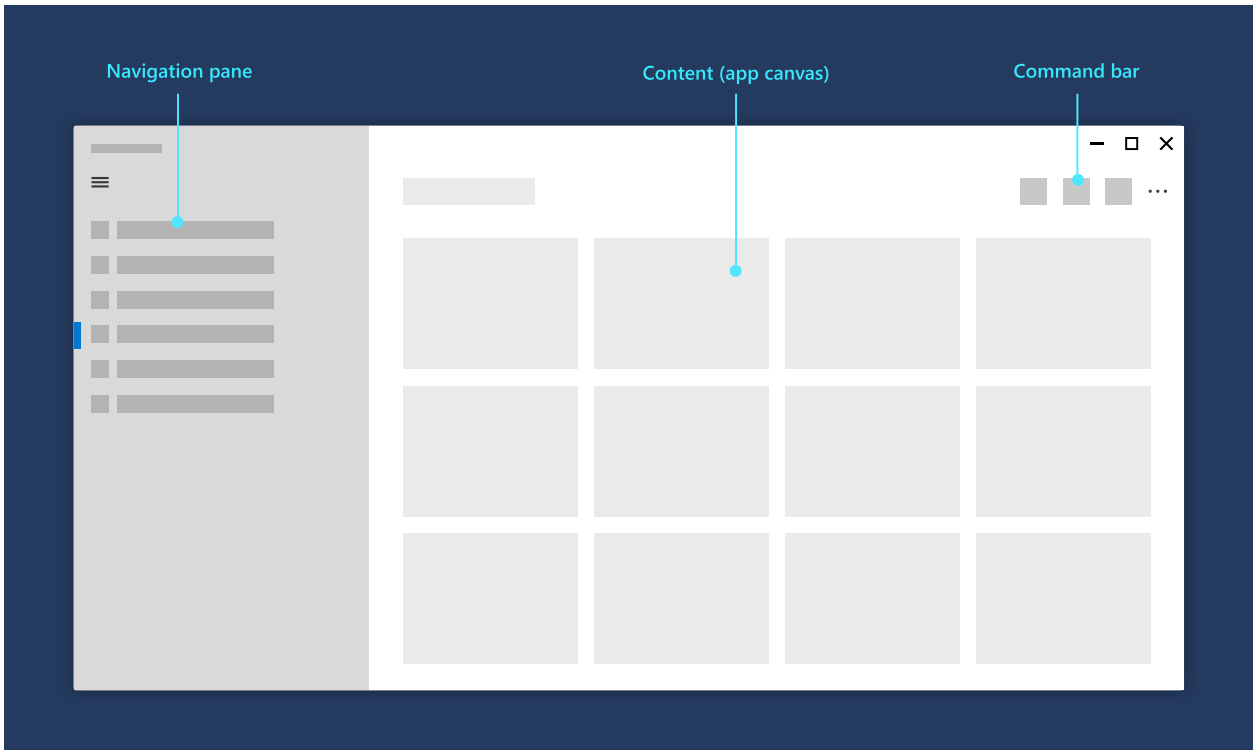
Let's start with the basic principles of good navigation design:

- **Consistency:** Meet user expectations.

- **Simplicity:** Don't do more than you need to.
- **Clarity:** Provide clear paths and options.

Consistency

Navigation should be consistent with user expectations. Using standard controls that users are familiar with and following standard conventions for icons, location, and styling will make navigation predictable and intuitive for users.

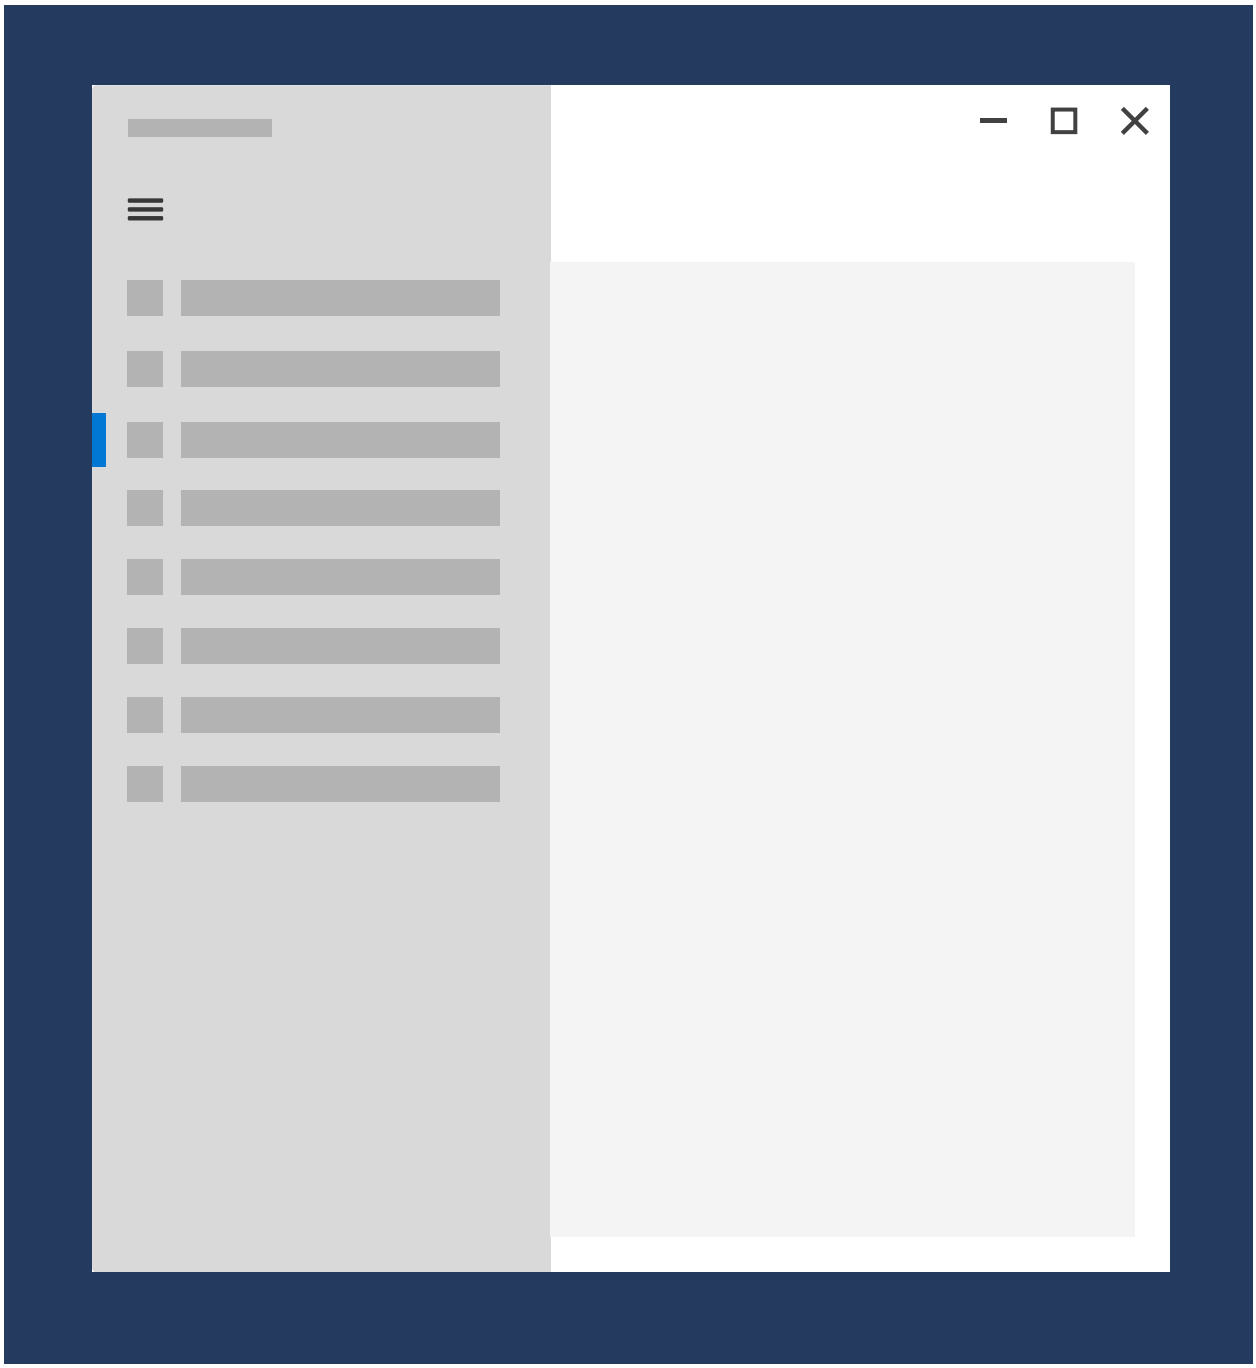


> *Users expect to find certain UI elements in standard locations.*

Simplicity

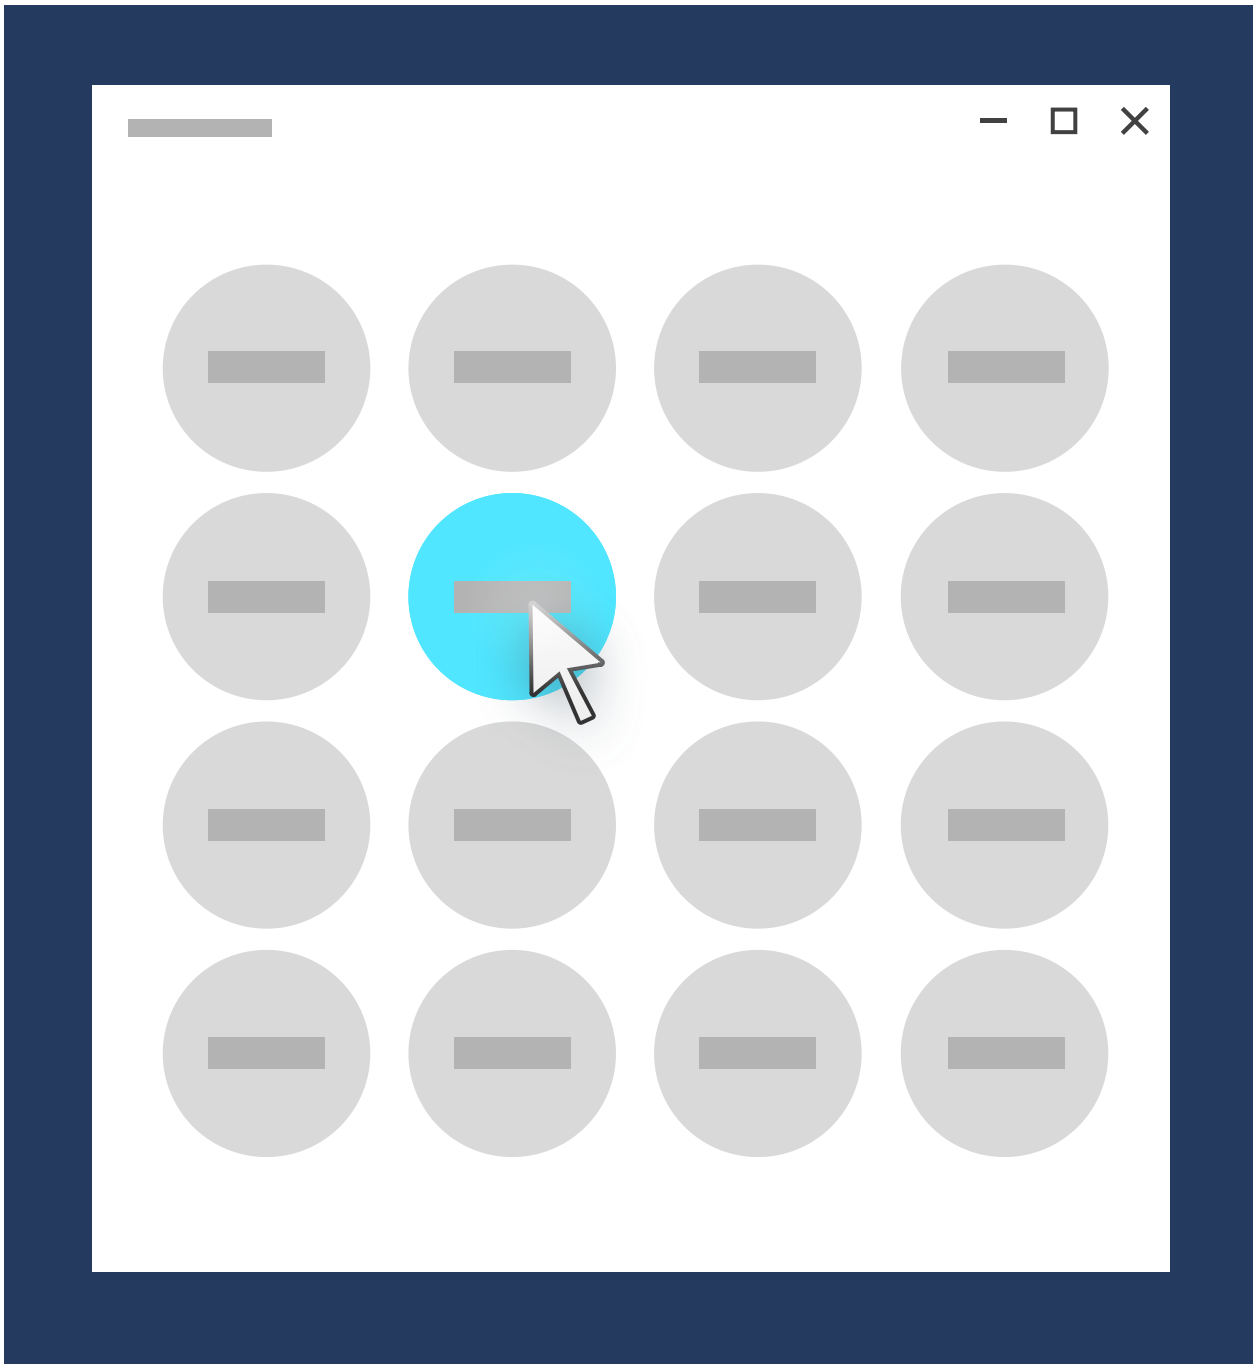
Fewer navigation items simplify decision making for users. Providing easy access to important destinations and hiding less important items will help users get where they want, faster.

Do



Present navigation items in a familiar navigation menu.

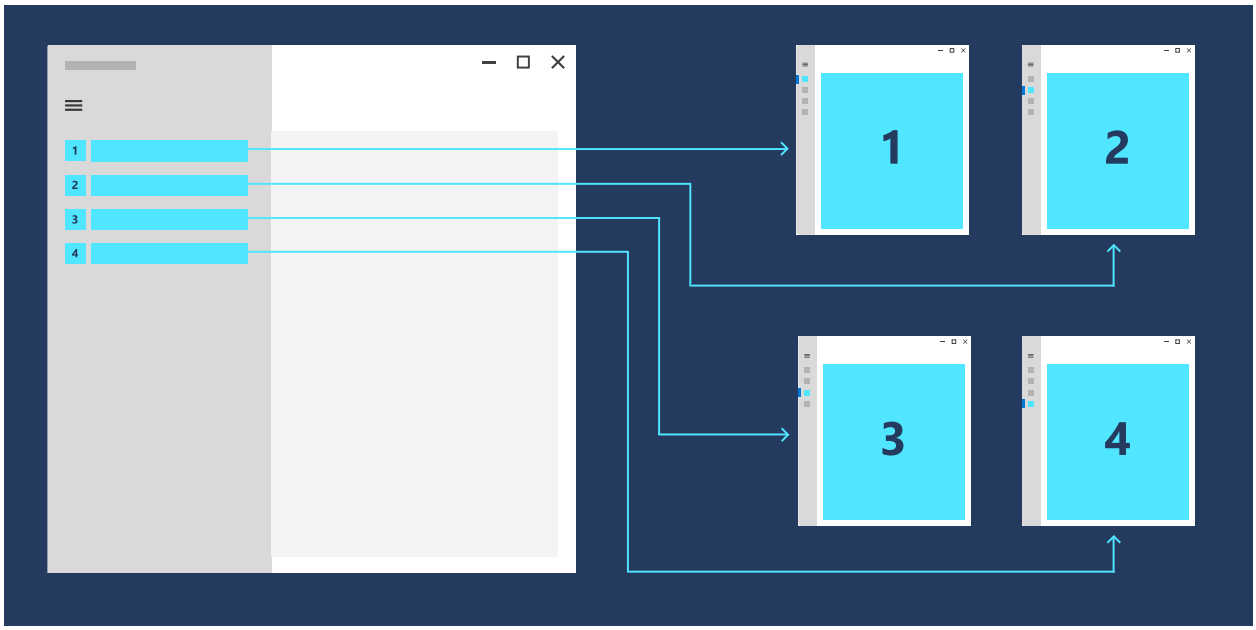
✕ Don’t



Don't overwhelm users with many navigation options.

Clarity

Clear paths allow for logical navigation for users. Making navigation options obvious and clarifying relationships between pages should prevent users from getting lost.



> *Destinations are clearly labeled so users know where they are.*

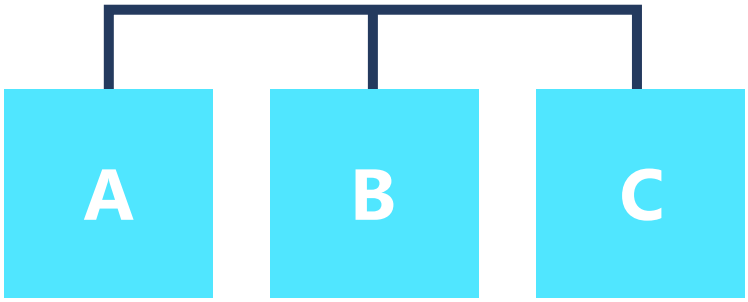
General recommendations

Now, let's take our design principles--consistency, simplicity, and clarity--and use them to come up with some general recommendations.

- Think about your users. Trace out typical paths they might take through your app, and for each page, think about why the user is there and where they might want to go.
- Avoid deep navigation hierarchies. If you go beyond two levels of navigation, provide a breadcrumb bar that shows the user where they are and let's them quickly get back out. Otherwise, you risk stranding your user in a deep hierarchy that they will have difficulty leaving.
- Avoid "pogo-sticking." Pogo-sticking occurs when there is related content, but navigating to it requires the user to go up a level and then down again.

Use the right structure

Now that you're familiar with general navigation principles, how should you structure your app? There are two general structures: flat and hierarchal.

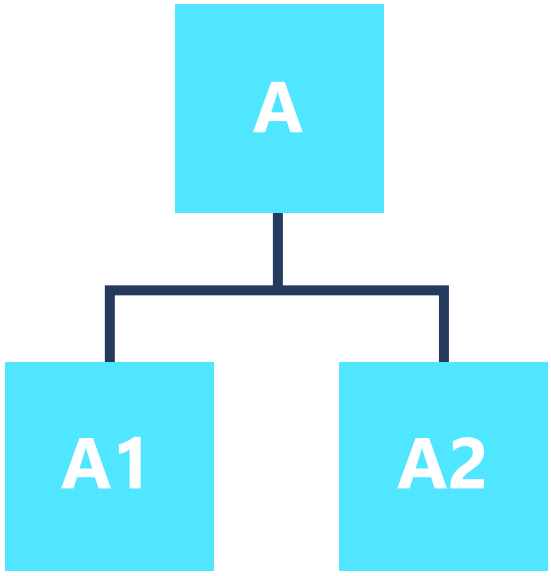


Flat/lateral

In a flat/lateral structure, pages exist side-by-side. You can go from one page to another in any order.

We recommend using a flat structure when:

- The pages can be viewed in any order.
- The pages are clearly distinct from each other and don't have an obvious parent/child relationship.
- There are less than 8 pages in the group.
  (When there are more pages, it might be difficult for users to understand how the pages are unique or to understand their current location within the group. If you don't think that's an issue for your app, go ahead and make the pages peers. Otherwise, consider using a hierarchical structure to break the pages into two or more smaller groups.)



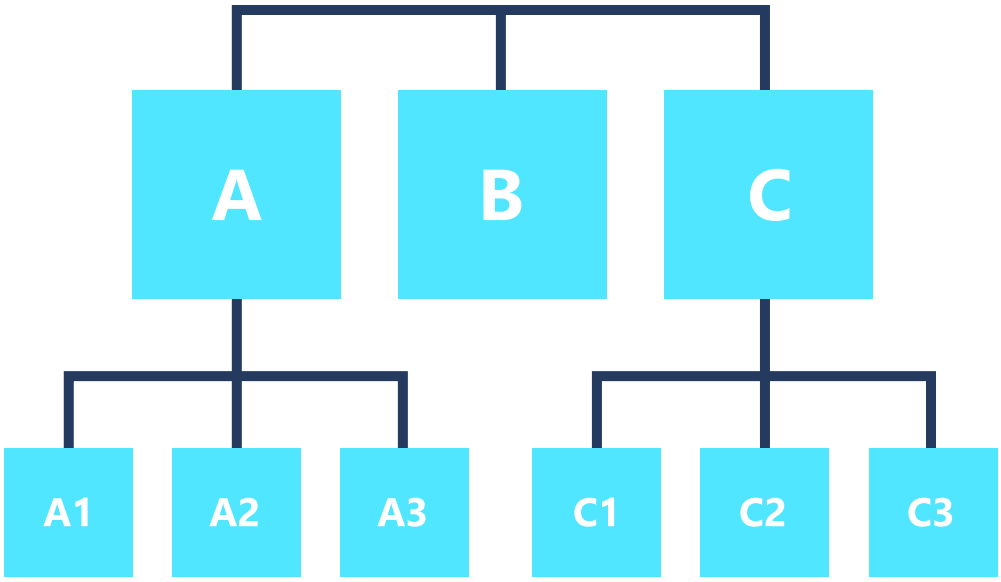
Hierarchical

In a hierarchical structure, pages are organized into a tree-like structure. Each child page has one parent, but a parent can have one or more child pages. To reach a child page, you travel through the parent.

Hierarchical structures are good for organizing complex content that spans lots of pages. The downside is some navigation overhead: the deeper the structure, the more clicks it takes to get from page to page.

We recommend a hierarchical structure when:

- Pages should be traversed in a specific order.
- There is a clear parent-child relationship between pages.
- There are more than 7 pages in the group.



Combining structures

You don't have to choose one structure or the other; many well-designed apps use both. An app can use flat structures for top-level pages that can be viewed in any order, and hierarchical structures for pages that have more complex relationships.

If your navigation structure has multiple levels, we recommend that peer-to-peer navigation elements only link to the peers within their current subtree. Consider the adjacent illustration, which shows a navigation structure that has two levels:

- At level 1, the peer-to-peer navigation element should provide access to pages A, B, and C.

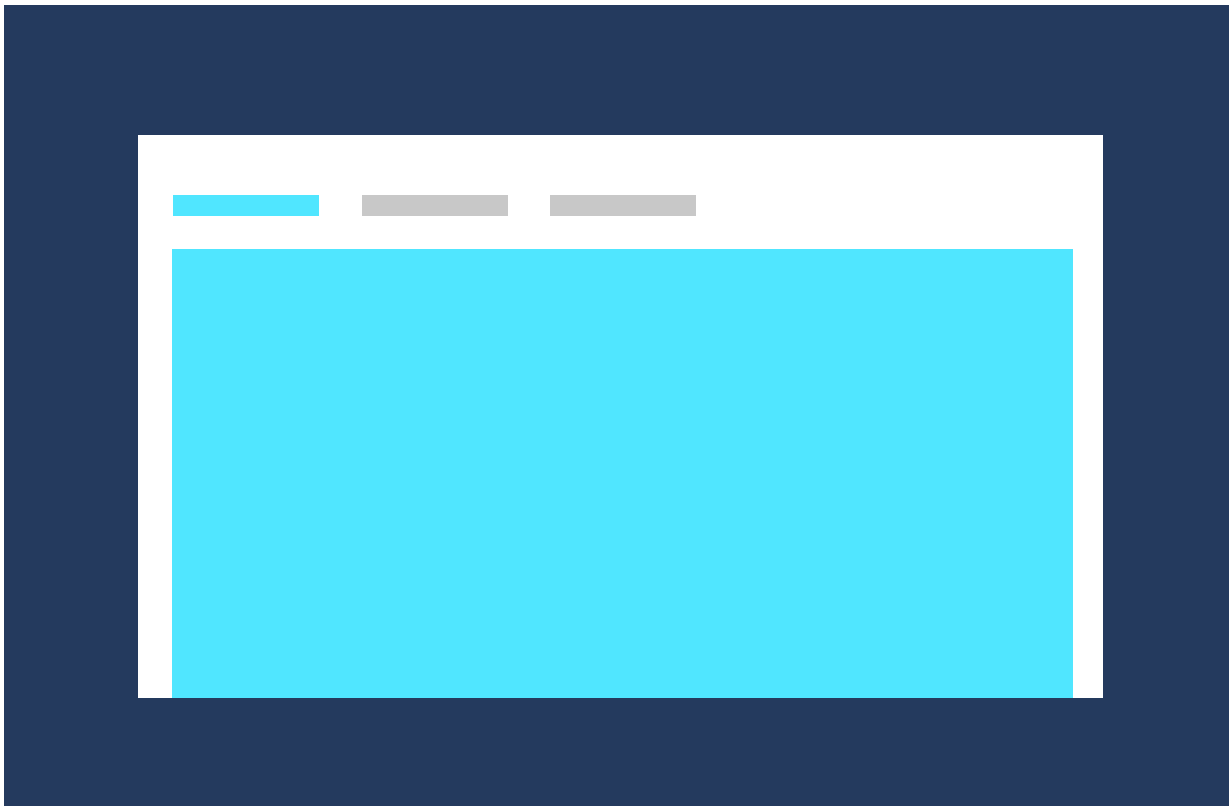
- At level 2, the peer-to-peer navigation elements for the A2 pages should only link to the other A2 pages. They should not link to level 2 pages in the C subtree.

Use the right controls

Once you've decided on a page structure, you need to decide how users navigate through those pages. XAML provides a variety of navigation controls to help ensure a consistent, reliable navigation experience in your app.

Frame

With few exceptions, any app that has multiple pages uses a frame. Typically, an app has a main page that contains the frame and a primary navigation element, such as a navigation view control. When the user selects a page, the frame loads and displays it.

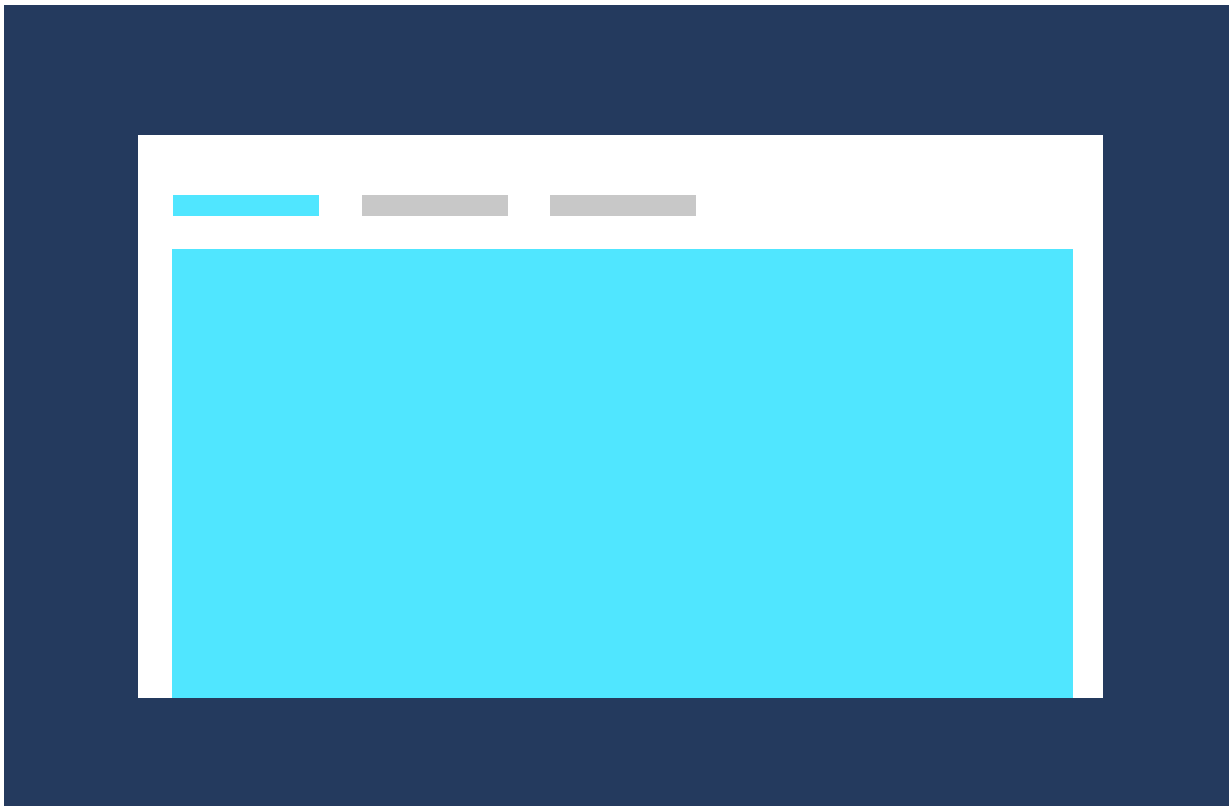


Top navigation

Displays a horizontal list of links to pages at the same level. The NavigationView control implements the top navigation pattern.

Use top navigation when:

- You want to show all navigation options on the screen.
- You desire more space for your app's content.
- Icons cannot clearly describe your navigation categories.

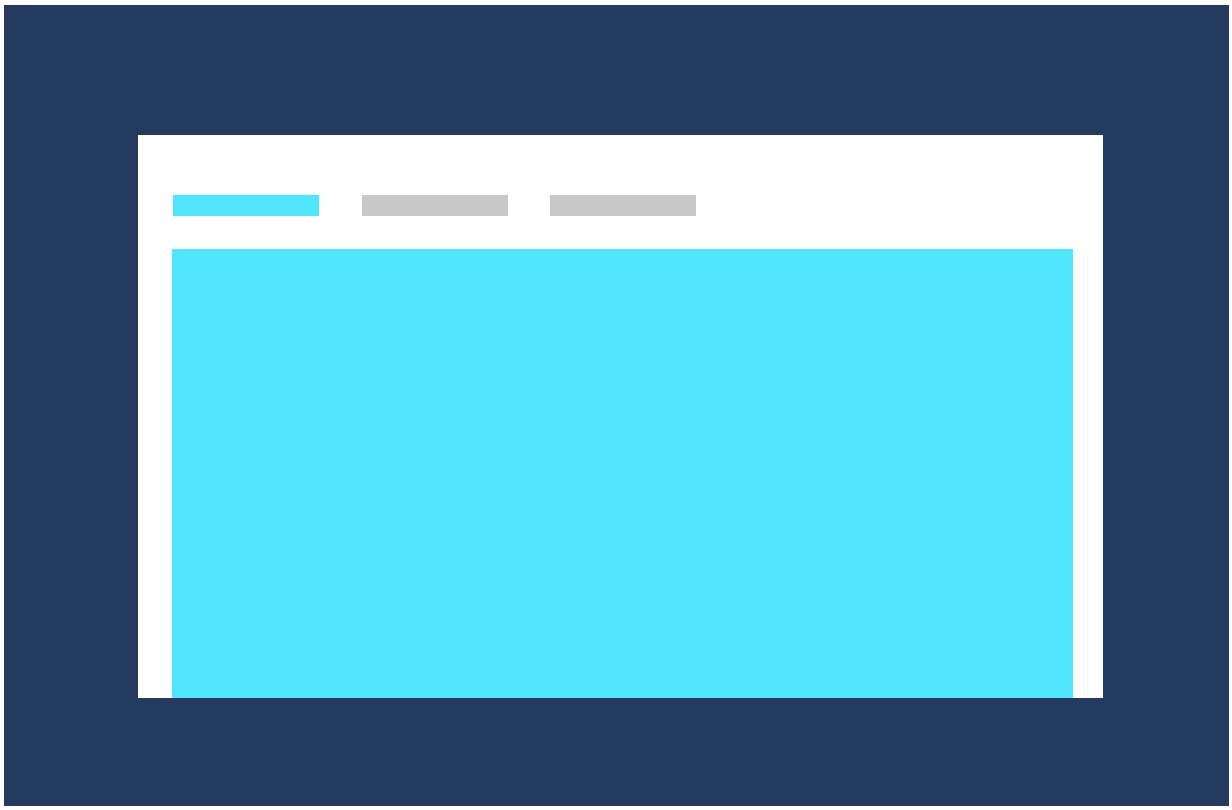


Tabs

Displays a horizontal set of tabs and their respective content. The TabView control is useful for displaying several pages (or documents) while giving the user the capability to rearrange, open, or close tabs.

Use tabs when:

- You want users to be able to dynamically open, close, or rearrange tabs.
- You expect that there might be a large number of tabs open at once.
- You expect users to be able to easily move tabs between windows in your application that use tabs, similar to web browsers like Microsoft Edge.

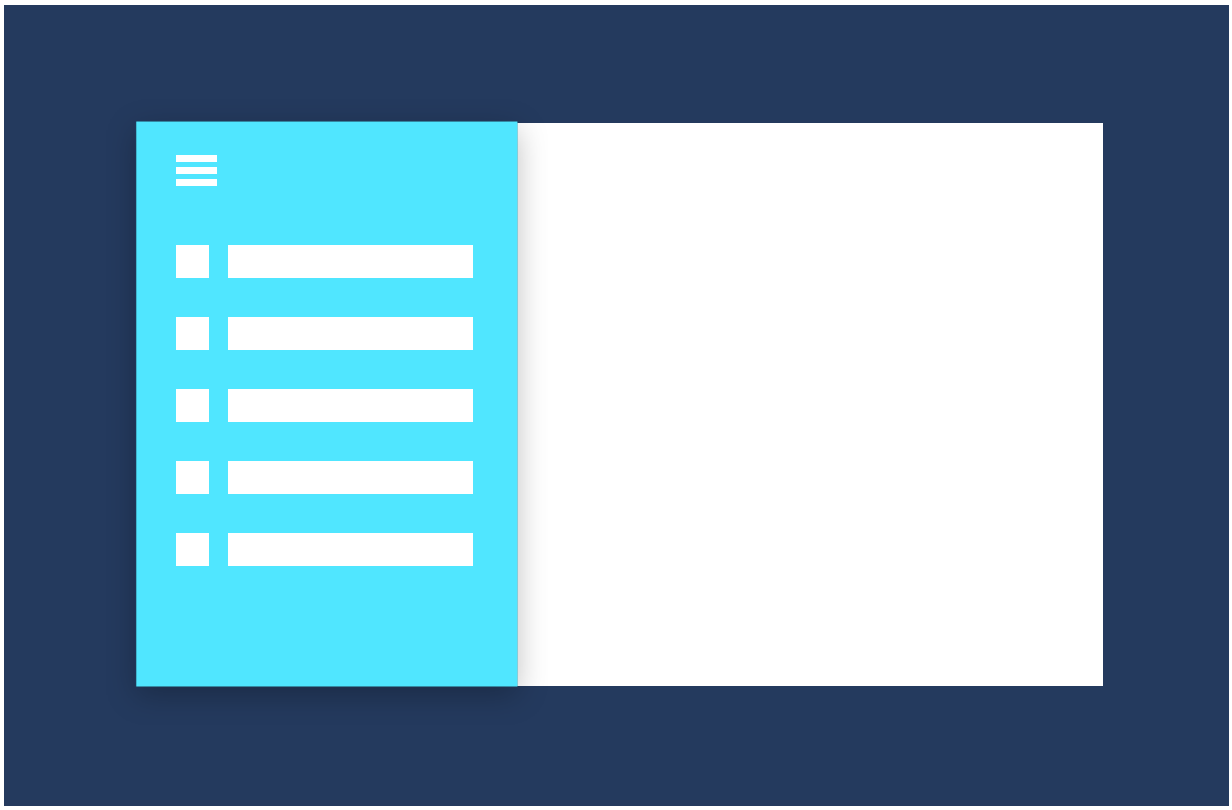


Breadcrumb

Displays a horizontal list of links to pages at each of the higher levels. The BreadcrumbBar control implements the top navigation pattern.

Use a breadcrumb when:

- You want to show the path to the current location
- You have many levels of navigation
- You expect users to be able to return to any previous level



Left navigation

Displays a vertical list of links to top-level pages. Use when:

- The pages exist at the top level.
- There are many navigation items (more than 5)
- You don't expect users to switch between pages frequently.

List/details

Displays a list of items. Selecting an item displays its corresponding page in the details section. Use when:

- You expect users to switch between child items frequently.
- You want to enable the user to perform high-level operations, such as deleting or sorting, on individual items or groups of items, and also want to enable the user to view or update the details for each item.

List/details is well suited for email inboxes, contact lists, and data entry.

Hyperlinks

Embedded navigation elements can appear in a page's content. Unlike other navigation elements, which should be consistent across the pages, content-embedded navigation elements are unique from page to page.

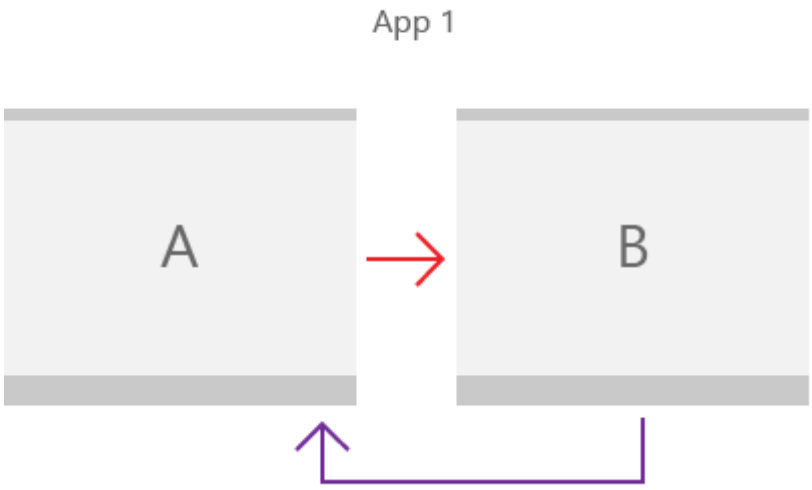
Next: Add navigation code to your app

The next article, Implement basic navigation, shows the code required to use a `Frame` control to enable basic navigation between two pages in your app.

Implement navigation between two pages

Article • 04/12/2023

Learn how to use a frame and pages to enable basic peer-to-peer navigation in your app.



Almost every app requires navigation between pages. Even a simple app with a single content page will typically have a settings page that requires navigation. In this article, we walk through the basics of adding a XAML `Page` to your app, and using a `Frame` to navigate between pages.

> **ⓘ Important**
>
> We use the **Blank App** template from Microsoft Visual Studio for this example. There are differences in the templates for Windows App SDK/WinUI 3 apps and UWP apps, so be sure to select the correct tab for your app type.

Windows App SDK

- ✓ **Applies to**: Windows App SDK/WinUI3
- ✓ **Important APIs**: Microsoft.UI.Xaml.Controls.Frame class, Microsoft.UI.Xaml.Controls.Page class, Microsoft.UI.Xaml.Navigation namespace

1. Create a blank app

Windows App SDK

To create a blank app in Visual Studio:

1. To set up your development computer, see Install tools for the Windows App SDK.
2. From the Microsoft Visual Studio start window, select **Create a new project**, OR, on the Visual Studio menu, choose **File** > **New** > **Project**.
3. In the **Create a new project** dialog's drop-down filters, select **C#** or **C++**, **Windows**, and **WinUI**, respectively.
4. Select the **Blank App, Packaged (WinUI 3 in Desktop)** project template, and click **Next**. That template creates a desktop app with a WinUI 3-based user interface.
5. In the **Project name** box, enter `BasicNavigation`, and click **Create**.
6. To run the program, choose **Debug** > **Start Debugging** from the menu, or press F5. Build and run your solution on your development computer to confirm that the app runs without errors. A blank page is displayed.
7. To stop debugging and return to Visual Studio, exit the app, or click **Stop Debugging** from the menu.
8. Remove any example code that's included in the template from the `MainWindow.xaml` and `MainWindow` code-behind files.

> **Tip**
>
> For more info, see **Create your first WinUI 3 (Windows App SDK) project**.

2. Use a Frame to navigate between pages

When your app has multiple pages, you use a Frame to navigate between them. The `Frame` class supports various navigation methods such as Navigate, GoBack, and GoForward, and properties such as BackStack, ForwardStack, and BackStackDepth.

Windows App SDK

When you create a new Windows App SDK project in Visual Studio, the project template creates a `MainWindow` class (of type Microsoft.UI.Xaml.Window). However, it doesn't create a Frame or Page and doesn't provide any navigation code.

To enable navigation between pages, add a `Frame` as the root element of `MainWindow`. You can do that in the Application.OnLaunched method override in the `App.xaml` code-behind file. Open the `App` code-behind file, update the `OnLaunched` override, and handle the NavigationFailed event as shown here.

C#

```
// App.xaml.cs

protected override void
OnLaunched(Microsoft.UI.Xaml.LaunchActivatedEventArgs args)
{
    m_window = new MainWindow();

    // Create a Frame to act as the navigation context and navigate to
the first page
    Frame rootFrame = new Frame();
    rootFrame.NavigationFailed += OnNavigationFailed;
    // Navigate to the first page, configuring the new page
    // by passing required information as a navigation parameter
    rootFrame.Navigate(typeof(MainPage), args.Arguments);

    // Place the frame in the current Window
    m_window.Content = rootFrame;
    // Ensure the MainWindow is active
    m_window.Activate();
}

void OnNavigationFailed(object sender, NavigationFailedEventArgs e)
{
    throw new Exception("Failed to load Page " +
e.SourcePageType.FullName);
}
```

> **Note**
>
> For apps with more complex navigation, you will typically use a **NavigationView** as the root of MainWindow, and place a `Frame` as the content of the navigation view. For more info, see **Navigation view**.

The Navigate method is used to display content in this `Frame`. Here, `MainPage.xaml` is passed to the `Navigate` method, so the method loads `MainPage` in the `Frame`.

If the navigation to the app's initial window fails, a `NavigationFailed` event occurs, and this code throws an exception in the event handler.

3. Add basic pages

The **Blank App** template doesn't create multiple app pages for you. Before you can navigate between pages, you need to add some pages to your app.

Windows App SDK

To add a new item to your app:

1. In **Solution Explorer**, right-click the `BasicNavigation` project node to open the context menu.
2. Choose **Add** > **New Item** from the context menu.
3. In the **Add New Item** dialog box, select the **WinUI** node in the left pane, then choose **Blank Page (WinUI 3)** in the middle pane.
4. In the **Name** box, enter `MainPage` and press the **Add** button.
5. Repeat steps 1-4 to add the second page, but in the **Name** box, enter `Page2`.

Now, these files should be listed as part of your `BasicNavigation` project.

C#	C++
• MainPage.xaml • MainPage.xaml.cs • Page2.xaml • Page2.xaml.cs	• MainPage.xaml • MainPage.xaml.cpp • MainPage.xaml.h • Page2.xaml • Page2.xaml.cpp • Page2.xaml.h

> **ⓘ Important**
>
> **For C++ projects**, you must add a `#include` directive in the header file of each page that references another page. For the inter-page navigation example presented here, mainpage.xaml.h file contains `#include "Page2.xaml.h"`, in turn, page2.xaml.h contains `#include "MainPage.xaml.h"`.
>
> C++ page templates also include an example `Button` and click handler code that you will need to remove from the XAML and code-behind files for the page.

Add content to the pages

In `MainPage.xaml`, replace the existing page content with the following content:

XAML

```
<Grid>
    <TextBlock x:Name="pageTitle" Text="Main Page"
               Margin="16" Style="{StaticResource TitleTextBlockStyle}"/>
    <HyperlinkButton Content="Click to go to page 2"
                     Click="HyperlinkButton_Click"
                     HorizontalAlignment="Center"/>
</Grid>
```

This XAML adds:

- A TextBlock element named `pageTitle` with its Text property set to `Main Page` as a child element of the root Grid.
- A HyperlinkButton element that is used to navigate to the next page as a child element of the root Grid.

In the `MainPage` code-behind file, add the following code to handle the `Click` event of the HyperlinkButton you added to enable navigation to `Page2.xaml`.

Windows App SDK

C#

```
// MainPage.xaml.cs

private void HyperlinkButton_Click(object sender, RoutedEventArgs e)
{
    Frame.Navigate(typeof(Page2));
}
```

`MainPage` is a subclass of the Page class. The `Page` class has a read-only Frame property that gets the `Frame` containing the `Page`. When the `Click` event handler of the `HyperlinkButton` in `MainPage` calls `Frame.Navigate(typeof(Page2))`, the `Frame` displays the content of `Page2.xaml`.

Whenever a page is loaded into the frame, that page is added as a PageStackEntry to the BackStack or ForwardStack of the Frame, allowing for history and backwards navigation.

Now, do the same in `Page2.xaml`. Replace the existing page content with the following content:

XAML

```
<Grid>
    <TextBlock x:Name="pageTitle" Text="Page 2"
               Margin="16" Style="{StaticResource TitleTextBlockStyle}"/>
    <HyperlinkButton Content="Click to go to main page"
                     Click="HyperlinkButton_Click"
                     HorizontalAlignment="Center"/>
</Grid>
```

In the `Page2` code-behind file, add the following code to handle the `Click` event of the HyperlinkButton to navigate to `MainPage.xaml`.

Windows App SDK

C#

```
// Page2.xaml.cs

private void HyperlinkButton_Click(object sender, RoutedEventArgs e)
{
    Frame.Navigate(typeof(MainPage));
}
```

Build and run the app. Click the link that says "Click to go to page 2". The second page that says "Page 2" at the top should be loaded and displayed in the frame. Now click the link on Page 2 to go back to Main Page.

4. Pass information between pages

Your app now navigates between two pages, but it really doesn't do anything interesting yet. Often, when an app has multiple pages, the pages need to share information. Now you'll pass some information from the first page to the second page.

In `MainPage.xaml`, replace the `HyperlinkButton` you added earlier with the following StackPanel. This adds a TextBlock label and a TextBox `name` for entering a text string.

XAML

```
<StackPanel VerticalAlignment="Center">
    <TextBlock HorizontalAlignment="Center" Text="Enter your name"/>
    <TextBox HorizontalAlignment="Center" Width="200" x:Name="name"/>
    <HyperlinkButton Content="Click to go to page 2"
                             Click="HyperlinkButton_Click"
```

```
                                HorizontalAlignment="Center"/>
</StackPanel>
```

Now you'll use the second overload of the `Navigate` method and pass the text from the text box as the second parameter. Here's the signature of this `Navigate` overload:

C#

```
public bool Navigate(System.Type sourcePageType, object parameter);
```

In the `HyperlinkButton_Click` event handler of the `MainPage` code-behind file, add a second parameter to the `Navigate` method that references the `Text` property of the `name` text box.

Windows App SDK

C#

```
// MainPage.xaml.cs

private void HyperlinkButton_Click(object sender, RoutedEventArgs e)
{
    Frame.Navigate(typeof(Page2), name.Text);
}
```

In `Page2.xaml`, replace the `HyperlinkButton` you added earlier with the following `StackPanel`. This adds a TextBlock for displaying the text string passed from `MainPage`.

XAML

```
<StackPanel VerticalAlignment="Center">
    <TextBlock HorizontalAlignment="Center" x:Name="greeting"/>
    <HyperlinkButton Content="Click to go to page 1"
                     Click="HyperlinkButton_Click"
                     HorizontalAlignment="Center"/>
</StackPanel>
```

In the `Page2` code-behind file, add the following code to override the `OnNavigatedTo` method:

Windows App SDK

C#

```
// Page2.xaml.cs

protected override void OnNavigatedTo(NavigationEventArgs e)
{
    if (e.Parameter is string &&
!string.IsNullOrWhiteSpace((string)e.Parameter))
    {
        greeting.Text = $"Hello, {e.Parameter.ToString()}";
    }
    else
    {
        greeting.Text = "Hello!";
    }
    base.OnNavigatedTo(e);
}
```

Run the app, type your name in the text box, and then click the link that says `Click to go to page 2`.

When the `Click` event of the `HyperlinkButton` in `MainPage` calls `Frame.Navigate(typeof(Page2), name.Text)`, the `name.Text` property is passed to `Page2`, and the value from the event data is used for the message displayed on the page.

5. Cache a page

Page content and state is not cached by default, so if you'd like to cache information, you must enable it in each page of your app.

In our basic peer-to-peer example, when you click the `Click to go to page 1` link on `Page2`, the `TextBox` (and any other field) on `MainPage` is set to its default state. One way to work around this is to use the NavigationCacheMode property to specify that a page be added to the frame's page cache.

By default, a new page instance is created with its default values every time navigation occurs. In `MainPage.xaml`, set `NavigationCacheMode` to `Enabled` (in the opening `Page` tag) to cache the page and retain all content and state values for the page until the page cache for the frame is exceeded. Set NavigationCacheMode to Required if you want to ignore CacheSize limits, which specify the number of pages in the navigation history that can be cached for the frame. However, keep in mind that cache size limits might be crucial, depending on the memory limits of a device.

XAML

```
<Page
    x:Class="BasicNavigation.MainPage"
    ...
    mc:Ignorable="d"
    NavigationCacheMode="Enabled">
```

Now, when you click back to main page, the name you entered in the text box is still there.

6. Customize page transition animations

By default, each page is animated into the frame when navigation occurs. The default animation is an "entrance" animation that causes the page to slide up from the bottom of the window. However, you can choose different animation options that better suit the navigation of your app. For example, you can use a "drill in" animation to give the feeling that the user is going deeper into your app, or a horizontal slide animation to give the feeling that two pages are peers. For more info, see Page transitions.

These animations are represented by sub-classes of NavigationTransitionInfo. To specify the animation to use for a page transition, you'll use the third overload of the `Navigate` method and pass a `NavigationTransitionInfo` sub-class as the third parameter (`infoOverride`). Here's the signature of this `Navigate` overload:

C#

```
public bool Navigate(System.Type sourcePageType,
                     object parameter,
                     NavigationTransitionInfo infoOverride);
```

In the `HyperlinkButton_Click` event handler of the `MainPage` code-behind file, add a third parameter to the `Navigate` method that sets the `infoOverride` parameter to a SlideNavigationTransitionInfo with its Effect property set to FromRight.

Windows App SDK

C#

```
// MainPage.xaml.cs

private void HyperlinkButton_Click(object sender, RoutedEventArgs e)
{
    Frame.Navigate(typeof(Page2),
                   name.Text,
```

```
                    new SlideNavigationTransitionInfo()
                        { Effect =
SlideNavigationTransitionEffect.FromRight});
}
```

In the `HyperlinkButton_Click` event handler of the `Page2` code-behind file, set the `infoOverride` parameter to a SlideNavigationTransitionInfo with its Effect property set to FromLeft.

Windows App SDK

C#

```
// Page2.xaml.cs

private void HyperlinkButton_Click(object sender, RoutedEventArgs e)
{
    Frame.Navigate(typeof(MainPage),
                    null,
                    new SlideNavigationTransitionInfo()
                        { Effect =
SlideNavigationTransitionEffect.FromLeft});
}
```

Now, when you navigate between pages, the pages slide left and right, which provides a more natural feeling for this transition and reinforces the connection between the pages.

Navigation history and backwards navigation for Windows apps

Article • 05/24/2022

> **Important APIs**: BackRequested event, SystemNavigationManager class, OnNavigatedTo

The Windows app provides a consistent back navigation system for traversing the user's navigation history within an app and, depending on the device, from app to app.

To implement backwards navigation in your app, place a back button at the top left corner of your app's UI. The user expects the back button to navigate to the previous location in the app's navigation history. Note that it's up to you to decide which navigation actions to add to the navigation history and how to respond to the back button press.

For most apps that have multiple pages, we recommend that you use the NavigationView control to provide the navigation framework for your app. It adapts to a variety of screen sizes and supports both *top* and *left* navigation styles. If your app uses the `NavigationView` control, then you can use NavigationView's built-in back button.

> ⓘ **Note**
>
> The guidelines and examples in this article should be used when you implement navigation without using the `NavigationView` control. If you use `NavigationView`, this information provides useful background knowledge, but you should use the specific guidance and examples in the **NavigationView** article

Back button

To create a back button, use the Button control with the `NavigationBackButtonNormalStyle` style, and place the button at the top left hand corner of your app's UI (for details, see the XAML code examples below).

XAML

```
<Page>
    <Grid>
        <Grid.RowDefinitions>
            <RowDefinition Height="Auto"/>
            <RowDefinition Height="*"/>
        </Grid.RowDefinitions>

        <Button x:Name="BackButton"
                Style="{StaticResource NavigationBackButtonNormalStyle}"
                IsEnabled="{x:Bind Frame.CanGoBack, Mode=OneWay}"
                ToolTipService.ToolTip="Back"/>

    </Grid>
</Page>
```

If your app has a top CommandBar, the Button control that is 44epx in height will not align with 48epx AppBarButtons very nicely. However, to avoid inconsistency, align the top of the Button control inside the 48epx bounds.

XAML

```
<Page>
    <Grid>
        <Grid.RowDefinitions>
            <RowDefinition Height="Auto"/>
            <RowDefinition Height="*"/>
        </Grid.RowDefinitions>

        <CommandBar>
            <CommandBar.Content>
                <Button x:Name="BackButton"
                        Style="{StaticResource
NavigationBackButtonNormalStyle}"
                        IsEnabled="{x:Bind Frame.CanGoBack, Mode=OneWay}"
                        ToolTipService.ToolTip="Back"
                        VerticalAlignment="Top"/>
            </CommandBar.Content>

            <AppBarButton Icon="Delete" Label="Delete"/>
            <AppBarButton Icon="Save" Label="Save"/>
        </CommandBar>
    </Grid>
</Page>
```

In order to minimize UI elements moving around in your app, show a disabled back button when there is nothing in the backstack (`IsEnabled="{x:Bind Frame.CanGoBack, Mode=OneWay}"`). However, if you expect your app will never have a backstack, you don't need to display the back button at all.

Optimize for different devices and inputs

This backwards navigation design guidance is applicable to all devices, but your users will benefit if you optimize for different form factors and methods of input.

To optimize your UI:

- **Desktop/Hub**: Draw the in-app back button on the top left corner of your app's UI.
- **Tablet Mode**: A hardware or software back button might be present on tablets, but we recommend drawing an in-app back button for clarity.
- **Xbox/TV**: Do not draw a back button; it will add unnecessary UI clutter. Instead, rely on the game pad B button to navigate backwards.

If your app will run on Xbox, create a custom visual trigger for Xbox to toggle the visibility of the button. If you use a NavigationView control, it will automatically toggle the back button's visibility when your app is running on Xbox.

We recommend handling the following events (in addition to the back button Click) to support the most common inputs for back navigation.

Event	Input
CoreDispatcher.AcceleratorKeyActivated	Alt+Left arrow, VirtualKey.GoBack
SystemNavigationManager.BackRequested	Windows + Backspace, Gamepad B button, Tablet Mode back button, Hardware back button
CoreWindow.PointerPressed	VirtualKey.XButton1 (Such as the back button found on some mice.)

Code examples

This section demonstrates how to handle back navigation using a variety of inputs.

Back button and back navigation

At a minimum, you need to handle the back button `Click` event and provide the code to perform the back navigation. You should also disable the back button when the backstack is empty.

This example code demonstrates how to implement backwards navigation behavior with a back button. The code responds to the Button Click event to navigate. The back

button is enabled or disabled in the OnNavigatedTo method, which is called when navigating to a new page.

The code is shown for `MainPage`, but you add this code to each page that supports back navigation. To avoid duplication, you can put the navigation related code in the `App` class in the `App.xaml.*` code-behind page.

XAML

```
<!-- MainPage.xaml -->
<Page x:Class="AppName.MainPage">
...
        <Button x:Name="BackButton" Click="BackButton_Click"
                Style="{StaticResource NavigationBackButtonNormalStyle}"
                IsEnabled="{x:Bind Frame.CanGoBack, Mode=OneWay}"
                ToolTipService.ToolTip="Back"/>
...
<Page/>
```

Code-behind:

C#

```
// MainPage.xaml.cs
private void BackButton_Click(object sender, RoutedEventArgs e)
{
    App.TryGoBack();
}

// App.xaml.cs
//
// Add this method to the App class.
public static bool TryGoBack()
{
    Frame rootFrame = Window.Current.Content as Frame;
    if (rootFrame.CanGoBack)
    {
        rootFrame.GoBack();
        return true;
    }
    return false;
}
```

Support access keys

Keyboard support is integral to ensuring your applications work great for users with different skills, abilities, and expectations. We recommend that you support accelerator

keys for both forward and back navigation because users who rely on these will expect both. For more info, see Keyboard interactions and Keyboard accelerators.

The common accelerator keys for forward and back navigation are Alt+Right arrow (forward) and Alt+Left arrow (back). To support these keys for navigation, handle the CoreDispatcher.AcceleratorKeyActivated event. You handle an event that's directly on the Window (rather than an element on the page) so the app responds to the accelerator keys regardless of which element has focus.

Add the code to the `App` class to support accelerator keys and forward navigation, as shown here. (This assumes that the previous code to support the back button has already been added.) You can see all the `App` code together at the end of the Code examples section.

C#

```
// App.xaml.cs
// Add event handler in OnLaunced.
protected override void OnLaunched(LaunchActivatedEventArgs e)
{
    // ...
    // Do not repeat app initialization when the Window already has content,
    // just ensure that the window is active
    if (rootFrame == null)
    {
        // ...
        // rootFrame.NavigationFailed += OnNavigationFailed;

        // Add support for accelerator keys.
        // Listen to the window directly so the app responds
        // to accelerator keys regardless of which element has focus.
        Window.Current.CoreWindow.Dispatcher.AcceleratorKeyActivated +=
            CoreDispatcher_AcceleratorKeyActivated;

        // ...

    }
}

// ...

// Add this code after the TryGoBack method added previously.
// Perform forward navigation if possible.
private bool TryGoForward()
{
    Frame rootFrame = Window.Current.Content as Frame;
    if (rootFrame.CanGoForward)
    {
        rootFrame.GoForward();
        return true;
    }
```

```
    return false;
}

// Invoked on every keystroke, including system keys such as Alt key
combinations.
// Used to detect keyboard navigation between pages even when the page
itself
// doesn't have focus.
private void CoreDispatcher_AcceleratorKeyActivated(CoreDispatcher sender,
AcceleratorKeyEventArgs e)
{
    // When Alt+Left are pressed navigate back.
    // When Alt+Right are pressed navigate forward.
    if (e.EventType == CoreAcceleratorKeyEventType.SystemKeyDown
        && (e.VirtualKey == VirtualKey.Left || e.VirtualKey ==
VirtualKey.Right)
        && e.KeyStatus.IsMenuKeyDown == true
        && !e.Handled)
    {
        if (e.VirtualKey == VirtualKey.Left)
        {
            e.Handled = TryGoBack();
        }
        else if (e.VirtualKey == VirtualKey.Right)
        {
            e.Handled = TryGoForward();
        }
    }
}
```

Handle system back requests

Windows devices provide various ways that the system can pass a back navigation request to your app. Some common ways are the B button on a gamepad, the Windows key + Backspace key shortcut, or the system back button in Tablet Mode; the exact options available depend on the device.

You can support system provided back requests from hardware and software system back keys by registering a listener for the SystemNavigationManager.BackRequested event.

Here's the code added to the `App` class to support system provided back requests. (This assumes that the previous code to support the back button has already been added.) You can see all the `App` code together at the end of the Code examples section.

C#

```
// App.xaml.cs
// Add event handler in OnLaunced.
```

```
protected override void OnLaunched(LaunchActivatedEventArgs e)
{
    // ...
    // Do not repeat app initialization when the Window already has content,
    // just ensure that the window is active
    if (rootFrame == null)
    {
        // ...
        // Add support for accelerator keys.
        // ... (Previously added code.)

        // Add support for system back requests.
        SystemNavigationManager.GetForCurrentView().BackRequested
            += System_BackRequested;

        // ...

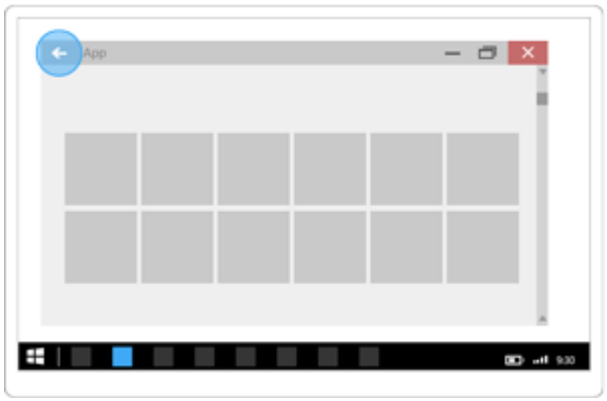
    }
}

// ...
// Handle system back requests.
private void System_BackRequested(object sender, BackRequestedEventArgs e)
{
    if (!e.Handled)
    {
        e.Handled = TryGoBack();
    }
}
```

System back behavior for backward compatibility

Previously, UWP apps used SystemNavigationManager.AppViewBackButtonVisibility to show or hide a system back button for backwards navigation. (This button raises a SystemNavigationManager.BackRequested event.) This API will continue to be supported to ensure backward compatibility, but we no longer recommend using the back button exposed by `AppViewBackButtonVisibility`. Instead, you should provide your own in-app back button as described in this article.

If you continue to use AppViewBackButtonVisibility, then the system UI renders the system back button inside the title bar. (The appearance and user interactions for the back button are unchanged from previous builds.)



Handle mouse navigation buttons

Some mice provide hardware navigation buttons for forward and back navigation. You can support these mouse buttons by handling the CoreWindow.PointerPressed event and checking for IsXButton1Pressed (back) or IsXButton2Pressed (forward).

Here's the code added to the `App` class to support mouse button navigation. (This assumes that the previous code to support the back button has already been added.) You can see all the `App` code together at the end of the Code examples section.

C#

```
// App.xaml.cs
// Add event handler in OnLaunced.
protected override void OnLaunched(LaunchActivatedEventArgs e)
{
    // ...
    // Do not repeat app initialization when the Window already has content,
    // just ensure that the window is active
    if (rootFrame == null)
    {
        // ...
        // Add support for system back requests.
        // ... (Previously added code.)

        // Add support for mouse navigation buttons.
        Window.Current.CoreWindow.PointerPressed +=
CoreWindow_PointerPressed;

        // ...

    }
}

// ...

// Handle mouse back button.
private void CoreWindow_PointerPressed(CoreWindow sender, PointerEventArgs
e)
```

```
{
    // For this event, e.Handled arrives as 'true'.
    if (e.CurrentPoint.Properties.IsXButton1Pressed)
    {
        e.Handled = !TryGoBack();
    }
    else if (e.CurrentPoint.Properties.IsXButton2Pressed)
    {
        e.Handled = !TryGoForward();
    }
}
```

All code added to App class

C#

```
// App.xaml.cs
//
// (Add event handlers in OnLaunched override.)
protected override void OnLaunched(LaunchActivatedEventArgs e)
{
    // ...
    // Do not repeat app initialization when the Window already has content,
    // just ensure that the window is active
    if (rootFrame == null)
    {
        // ...
        // rootFrame.NavigationFailed += OnNavigationFailed;

        // Add support for accelerator keys.
        // Listen to the window directly so the app responds
        // to accelerator keys regardless of which element has focus.
        Window.Current.CoreWindow.Dispatcher.AcceleratorKeyActivated +=
            CoreDispatcher_AcceleratorKeyActivated;

        // Add support for system back requests.
        SystemNavigationManager.GetForCurrentView().BackRequested
            += System_BackRequested;

        // Add support for mouse navigation buttons.
        Window.Current.CoreWindow.PointerPressed +=
CoreWindow_PointerPressed;

        // ...

    }
}

// ...

// (Add these methods to the App class.)
public static bool TryGoBack()
```

```
{
    Frame rootFrame = Window.Current.Content as Frame;
    if (rootFrame.CanGoBack)
    {
        rootFrame.GoBack();
        return true;
    }
    return false;
}

// Perform forward navigation if possible.
private bool TryGoForward()
{
    Frame rootFrame = Window.Current.Content as Frame;
    if (rootFrame.CanGoForward)
    {
        rootFrame.GoForward();
        return true;
    }
    return false;
}

// Invoked on every keystroke, including system keys such as Alt key
combinations.
// Used to detect keyboard navigation between pages even when the page
itself
// doesn't have focus.
private void CoreDispatcher_AcceleratorKeyActivated(CoreDispatcher sender,
AcceleratorKeyEventArgs e)
{
    // When Alt+Left are pressed navigate back.
    // When Alt+Right are pressed navigate forward.
    if (e.EventType == CoreAcceleratorKeyEventType.SystemKeyDown
        && (e.VirtualKey == VirtualKey.Left || e.VirtualKey ==
VirtualKey.Right)
        && e.KeyStatus.IsMenuKeyDown == true
        && !e.Handled)
    {
        if (e.VirtualKey == VirtualKey.Left)
        {
            e.Handled = TryGoBack();
        }
        else if (e.VirtualKey == VirtualKey.Right)
        {
            e.Handled = TryGoForward();
        }
    }
}

// Handle system back requests.
private void System_BackRequested(object sender, BackRequestedEventArgs e)
{
    if (!e.Handled)
    {
        e.Handled = TryGoBack();
```

```
    }
}

// Handle mouse back button.
private void CoreWindow_PointerPressed(CoreWindow sender, PointerEventArgs
e)
{
    // For this event, e.Handled arrives as 'true'.
    if (e.CurrentPoint.Properties.IsXButton1Pressed)
    {
        e.Handled = !TryGoBack();
    }
    else if (e.CurrentPoint.Properties.IsXButton2Pressed)
    {
        e.Handled = !TryGoForward();
    }
}
```

Guidelines for custom back navigation behavior

If you choose to provide your own back stack navigation, the experience should be consistent with other apps. We recommend that you follow the following patterns for navigation actions:

Navigation action	Add to navigation history?
Page to page, different peer groups	Yes In this illustration, the user navigates from level 1 of the app to level 2, crossing peer groups, so the navigation is added to the navigation history.

Navigation action	Add to navigation history?
	 In the next illustration, the user navigates between two peer groups at the same level, again crossing peer groups, so the navigation is added to the navigation history. Page to page, same peer group, no on-screen navigation element The user navigates from one page to another with the same peer group. There is no on-screen navigation element (such as NavigationView)	**Yes** In the following illustration, the user navigates between two pages in the same peer group, and the navigation should be added to the navigation history.

Navigation action	Add to navigation history?
that provides direct navigation to both pages.	Page to page, same peer group, with an on-screen navigation element The user navigates from one page to another in the same peer group. Both pages are shown in the same navigation element, such as NavigationView.	**It depends** Yes, add to the navigation history, with two notable exceptions. If you expect users of your app to switch between pages in the peer group frequently, or if you wish to preserve the navigational hierarchy, then do not add to the navigation history. In this case, when the user presses back, go back to the last page before the user navigated to the current peer group. Show a transient UI	**No**

Navigation action	Add to navigation history?
The app displays a pop-up or child window, such as a dialog, splash screen, or on-screen keyboard, or the app enters a special mode, such as multiple selection mode.	When the user presses the back button, dismiss the transient UI (hide the on-screen keyboard, cancel the dialog, etc) and return to the page that spawned the transient UI. Enumerate items The app displays content for an on-screen item, such as the details for the selected item in list/details list.	**No** Enumerating items is similar to navigating within a peer group. When the user presses back, navigate to the page that preceded the current page that has the item enumeration. 
Resuming

When the user switches to another app and returns to your app, we recommend returning to the last page in the navigation history.

Controls for Windows apps

Article • 03/03/2025

In Windows app development, a *control* is a UI element that displays content or enables interaction. Controls are the building blocks of the user interface. A *pattern* is a recipe for combining several controls to make something new.

We provide 45+ controls for you to use, ranging from simple buttons to powerful data controls like the grid view. These controls are a part of the Fluent Design System and can help you create a bold, scalable UI that looks great on all devices and screen sizes.

The articles in this section provide design guidance and coding instructions for adding controls & patterns to your Windows app.

General instructions and code examples

The topics highlighted here provide instructions and code examples for adding and styling controls in XAML and C#.

Add controls and handle events

There are 3 key steps to adding controls to your app: Add a control to your app UI, set properties on the control, and add code to the control's event handlers so that it does something.

Styling controls

You can customize the appearance of your apps in many ways by using the XAML framework. Styles let you set control properties and reuse those settings for a consistent appearance across multiple controls.

Get WinUI

Some controls are only available in WinUI, a NuGet package that contains new controls and UI features. To get it, see the WinUI overview and installation instructions.

Index of controls

The following table lists the common Windows app controls and patterns along with those that are exclusive to WinUI.

WinUI Gallery

Get the *WinUI Gallery* apps from the Microsoft Store to see XAML controls and the Fluent Design System in action. The **WinUI 3 Gallery** and **WinUI 2 Gallery** apps include interactive examples of most WinUI 3 and WinUI 2 controls, features, and functionality. The apps are an interactive companion to this website. When you have them installed, you can use links on individual control pages to launch the app and see the control in action.

- ✓ Get the **WinUI 3 Gallery** and the **WinUI 2 Gallery** from the Microsoft Store.
- ✓ Get the source code for both from GitHub (use the *main* branch for WinUI 3 and the *winui2* branch for WinUI 2).

Additional controls

Additional controls for Windows development are available from companies such as Telerik, SyncFusion, DevExpress, Infragistics, ComponentOne, and ActiPro. These controls provide additional support for enterprise and .NET developers by augmenting the standard system controls with custom controls and services.

Intro to controls and patterns

Article • 06/09/2022

In Windows app development, a *control* is a UI element that displays content or enables interaction. You create the UI for your app by using controls such as buttons, text boxes, and combo boxes to display data and get user input.

> **Important APIs**: Windows.UI.Xaml.Controls namespace

A *pattern* is a recipe for modifying a control or combining several controls to make something new. For example, the list/details pattern is a way that you can use a SplitView control for app navigation. Similarly, you can customize the template of a NavigationView control to implement the tab pattern.

In many cases, you can use a control as-is. But XAML controls separate function from structure and appearance, so you can make various levels of modification to make them fit your needs. In the Style section, you can learn how to use XAML styles and control templates to modify a control.

In this section, we provide guidance for each of the XAML controls you can use to build your app UI. To start, this article shows you how to add controls to your app. There are 3 key steps to using controls to your app:

- Add a control to your app UI.
- Set properties on the control, such as width, height, or foreground color.
- Add code to the control's event handlers so that it does something.

Add a control

You can add a control to an app in several ways:

- Use a design tool like Blend for Visual Studio or the Microsoft Visual Studio Extensible Application Markup Language (XAML) designer.
- Add the control to the XAML markup in the Visual Studio XAML editor.
- Add the control in code. Controls that you add in code are visible when the app runs, but are not visible in the Visual Studio XAML designer.

In Visual Studio, when you add and manipulate controls in your app, you can use many of the program's features, including the Toolbox, XAML designer, XAML editor, and the Properties window.

The Visual Studio Toolbox displays many of the controls that you can use in your app. To add a control to your app, double-click it in the Toolbox. For example, when you double-click the TextBox control, this XAML is added to the XAML view.

XAML

```
<TextBox HorizontalAlignment="Left" Text="TextBox" VerticalAlignment="Top"/>
```

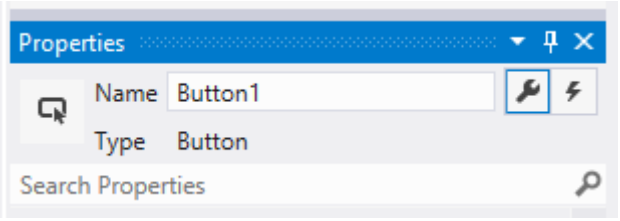
You can also drag the control from the Toolbox to the XAML designer.

Set the name of a control

To work with a control in code, you set its x:Name attribute and reference it by name in your code. You can set the name in the Visual Studio Properties window or in XAML. Here's how to set the name of the currently selected control by using the Name text box at the top of the Properties window.

To name a control

1. Select the element to name.
2. In the Properties panel, type a name into the Name text box.
3. Press Enter to commit the name.



Here's how to set the name of a control in the XAML editor by adding the x:Name attribute.

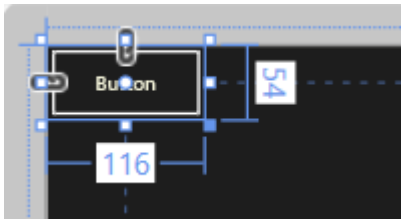
XAML

```
<Button x:Name="Button1" Content="Button"/>
```

Set the control properties

You use properties to specify the appearance, content, and other attributes of controls. When you add a control using a design tool, some properties that control size, position, and content might be set for you by Visual Studio. You can change some properties,

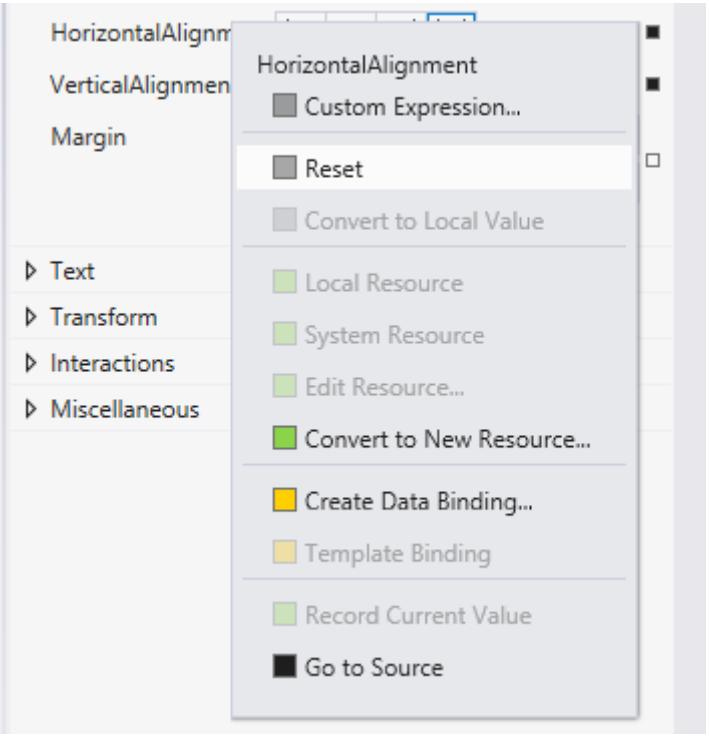
such as Width, Height or Margin, by selecting and manipulating the control in the Design view. This illustration shows some of the resizing tools available in Design view.



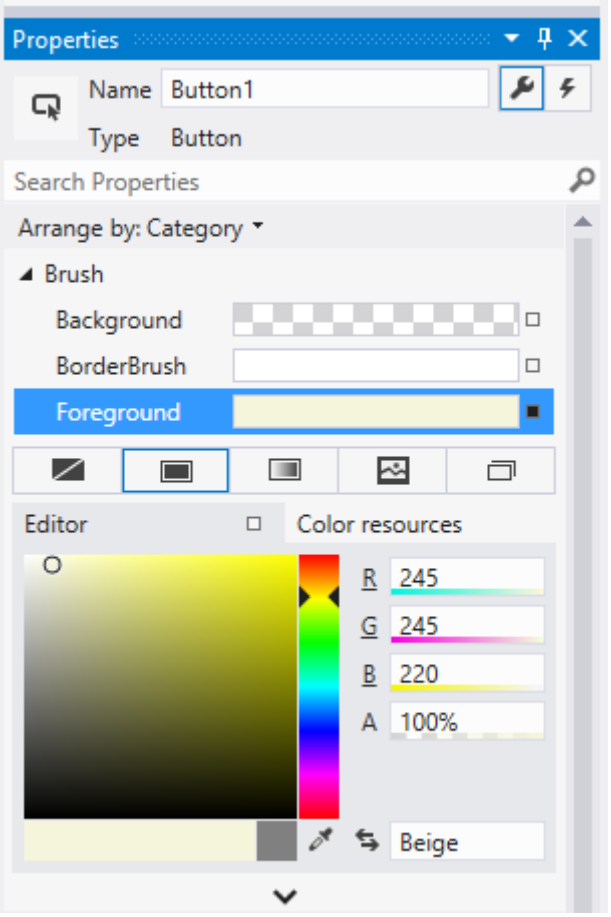
You might want to let the control be sized and positioned automatically. In this case, you can reset the size and position properties that Visual Studio set for you.

To reset a property

1. In the Properties panel, click the property marker next to the property value. The property menu opens.
2. In the property menu, click Reset.



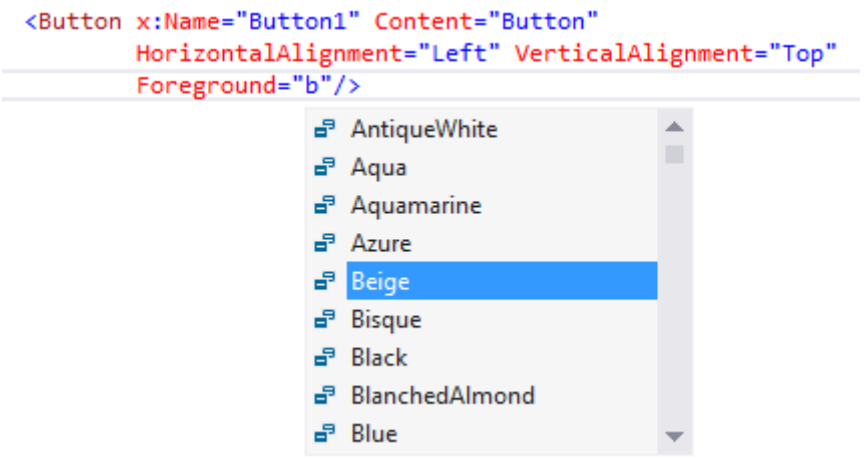
You can set control properties in the Properties window, in XAML, or in code. For example, to change the foreground color for a Button, you set the control's Foreground property. This illustration shows how to set the Foreground property by using the color picker in the Properties window.



Here's how to set the Foreground property in the XAML editor. Notice the Visual Studio IntelliSense window that opens to help you with the syntax.

```
<Button x:Name="Button1" Content="Button"
        HorizontalAlignment="Left" VerticalAlignment="Top"
        For/>
```

FontSize
FontStretch
FontStyle
FontWeight
Foreground
GotFocus
Grid
Height
Holding



Here's the resulting XAML after you set the Foreground property.

XAML

```
<Button x:Name="Button1" Content="Button"
        HorizontalAlignment="Left" VerticalAlignment="Top"
        Foreground="Beige"/>
```

Here's how to set the Foreground property in code.

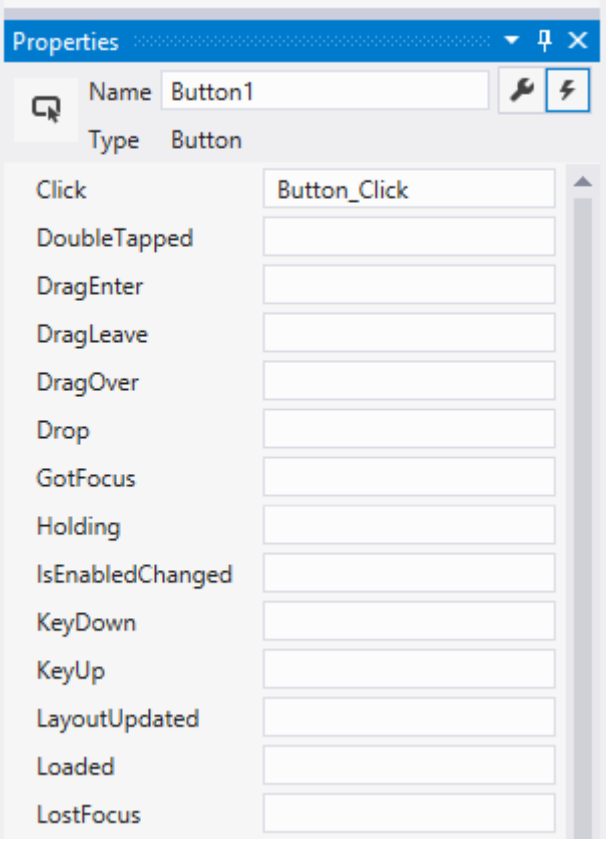
C#

```
Button1.Foreground = new SolidColorBrush(Windows.UI.Colors.Beige);
```

Create an event handler

Each control has events that enable you to respond to actions from your user or other changes in your app. For example, a Button control has a Click event that is raised when a user clicks the Button. You create a method, called an event handler, to handle the event. You can associate a control's event with an event handler method in the Properties window, in XAML, or in code. For more info about events, see Events and routed events overview.

To create an event handler, select the control and then click the Events tab at the top of the Properties window. The Properties window lists all of the events available for that control. Here are some of the events for a Button.



To create an event handler with the default name, double-click the text box next to the event name in the Properties window. To create an event handler with a custom name, type the name of your choice into the text box and press enter. The event handler is created and the code-behind file is opened in the code editor. The event handler method has 2 parameters. The first is `sender`, which is a reference to the object where the handler is attached. The `sender` parameter is an **Object** type. You typically cast `sender` to a more precise type if you expect to check or change the state on the `sender` object itself. Based on your own app design, you expect a type that is safe to cast the `sender` to, based on where the handler is attached. The second value is event data, which generally appears in signatures as the `e` or `args` parameter.

Here's code that handles the Click event of a Button named `Button1`. When you click the button, the Foreground property of the Button you clicked is set to blue.

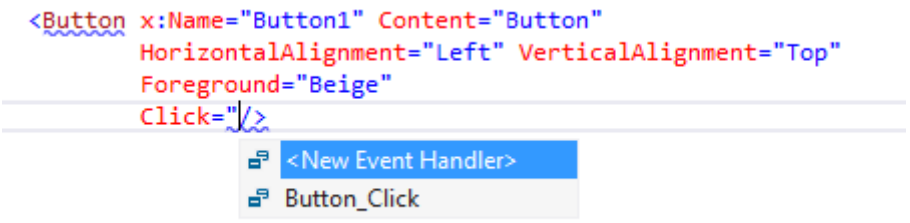
C#

```
private void Button_Click(object sender, RoutedEventArgs e)
{
    Button b = (Button)sender;
    b.Foreground = new SolidColorBrush(Windows.UI.Colors.Blue);
}
```

You can also associate an event handler in XAML. In the XAML editor, type in the event name that you want to handle. Visual Studio shows an IntelliSense window when you begin typing. After you specify the event, you can double-click `<New Event Handler>` in

the IntelliSense window to create a new event handler with the default name, or select an existing event handler from the list.

Here's the IntelliSense window that appears. It helps you create a new event handler or select an existing event handler.



This example shows how to associate a Click event with an event handler named Button_Click in XAML.

XAML

```
<Button Name="Button1" Content="Button" Click="Button_Click"/>
```

You can also associate an event with its event handler in the code-behind. Here's how to associate an event handler in code.

C#

```
Button1.Click += new RoutedEventHandler(Button_Click);
```

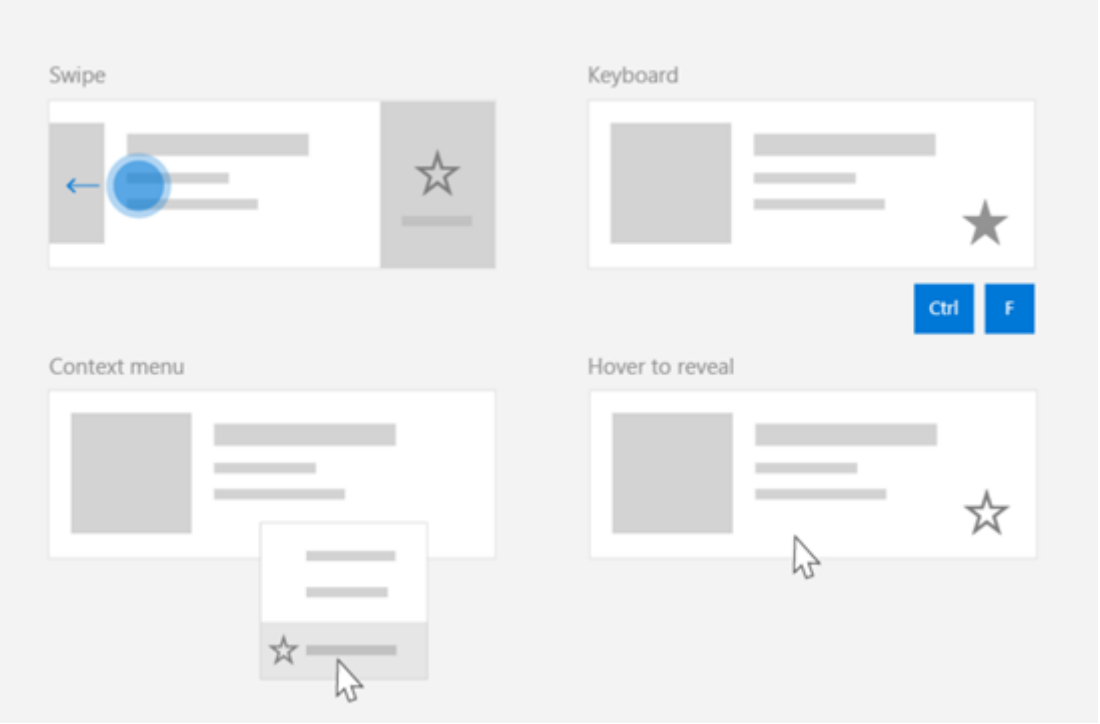
Commanding in Windows apps using StandardUICommand, XamlUICommand, and ICommand

Article • 01/03/2023

In this topic, we describe commanding in Windows applications. Specifically, we discuss how you can use the XamlUICommand and StandardUICommand classes (along with the ICommand interface) to share and manage commands across various control types, regardless of the device and input type being used.



Share commands across various controls, regardless of device and input type

Important APIs

- Windows.UI.Xaml.Input.ICommand and System.Windows.Input.ICommand
- XamlUICommand
- StandardUICommand

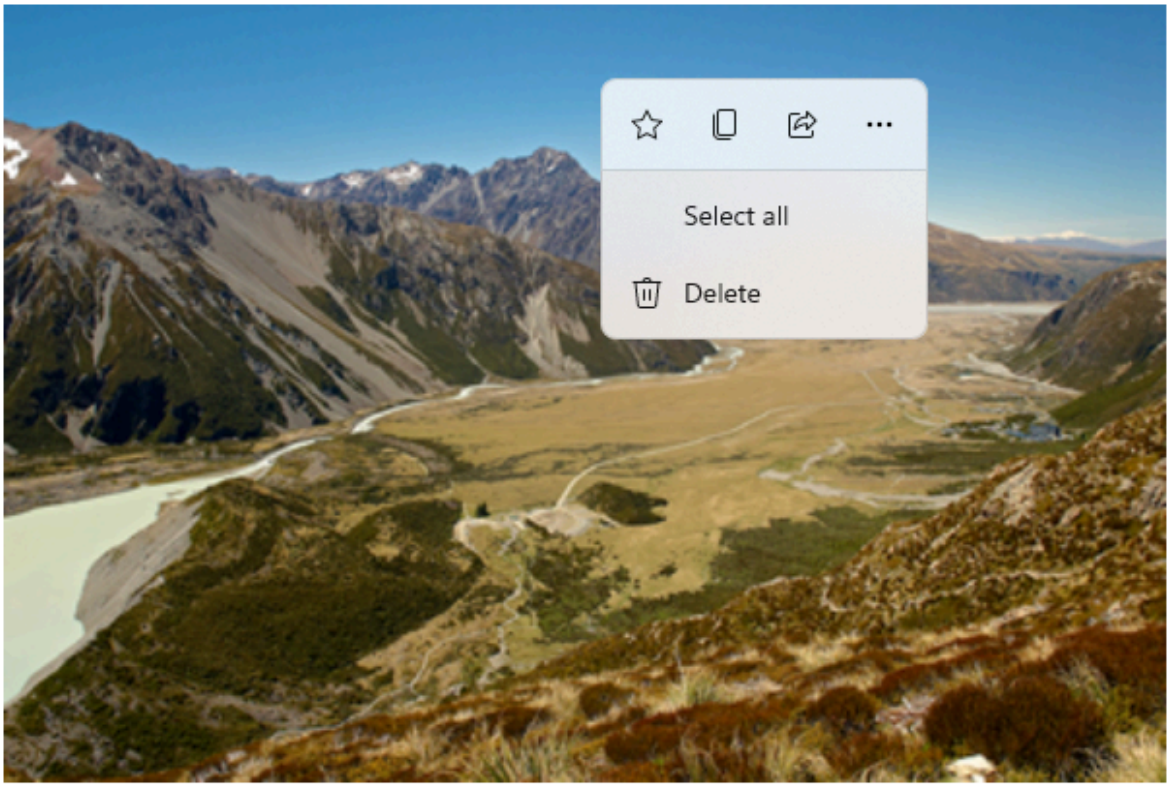
Overview

Commands can be invoked directly through UI interactions like clicking a button or selecting an item from a context menu. They can also be invoked indirectly through an input device such as a keyboard accelerator, gesture, speech recognition, or an

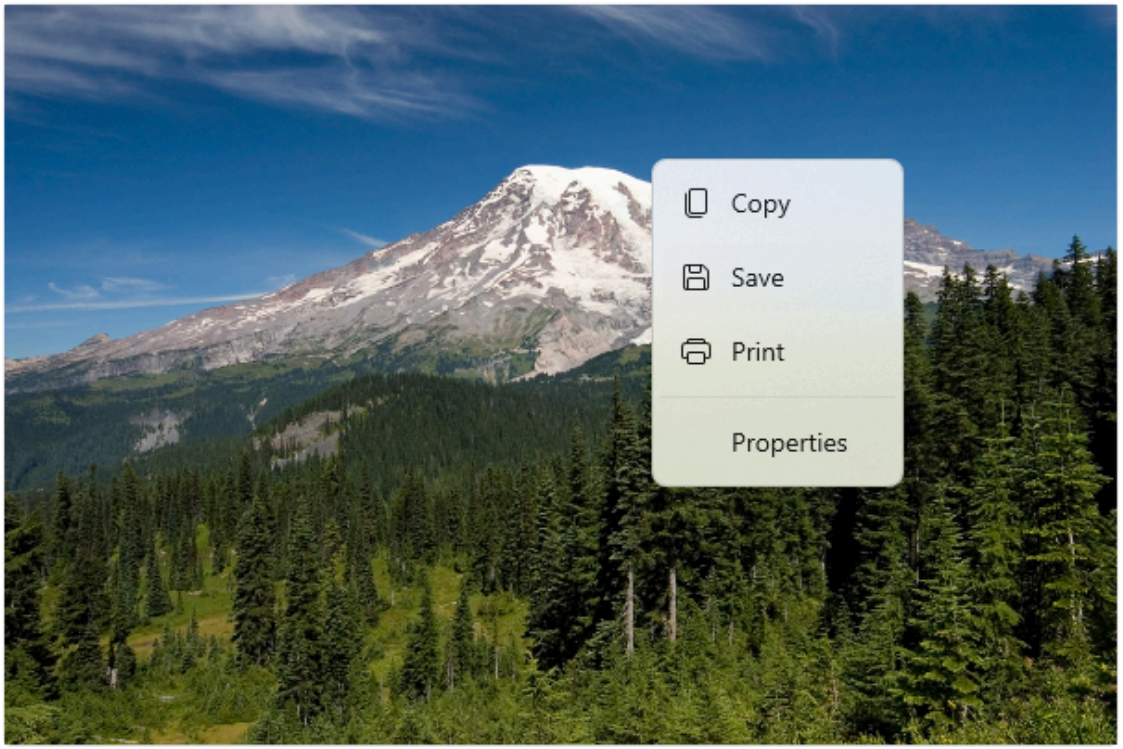
automation/accessibility tool. Once invoked, the command can then be handled by a control (text navigation in an edit control), a window (back navigation), or the application (exit).

Commands can operate on a specific context within your app, such as deleting text or undoing an action, or they can be context-free, such as muting audio or adjusting brightness.

The following image shows two command interfaces (a CommandBar and a floating contextual CommandBarFlyout) that share some of the same commands.



Command bar



Context menu in the Microsoft Photos gallery

Command interactions

Due to the variety of devices, input types, and UI surfaces that can affect how a command is invoked, we recommend exposing your commands through as many commanding surfaces as possible. These can include a combination of Swipe, MenuBar, CommandBar, CommandBarFlyout, and traditional context menu.

For critical commands, use input-specific accelerators. Input accelerators let a user perform actions more quickly depending on the input device they're using.

Here are some common input accelerators for various input types:

- **Pointer** - Mouse & Pen hover buttons
- **Keyboard** - Shortcuts (access keys and accelerator keys)
- **Touch** - Swipe
- **Touch** - Pull to refresh data

You must consider the input type and user experiences to make your application's functionality universally accessible. For example, collections (especially user editable ones) typically include a variety of specific commands that are performed quite differently depending on the input device.

The following table shows some typical collection commands and ways to expose those commands.

Expand table

Command	Input-agnostic	Mouse accelerator	Keyboard accelerator	Touch accelerator
Delete item	Context menu	Hover button	DEL key	Swipe to delete
Flag item	Context menu	Hover button	Ctrl+Shift+G	Swipe to flag
Refresh data	Context menu	N/A	F5 key	Pull to refresh
Favorite an item	Context menu	Hover button	F, Ctrl+S	Swipe to favorite

Always provide a context menu We recommend including all relevant contextual commands in a traditional context menu or CommandBarFlyout, as both are supported for all input types. For example, if a command is exposed only during a pointer hover event, it cannot be used on a touch-only device.

Commands in Windows applications

There are a few ways you can share and manage commanding experiences in a Windows application. You can define event handlers for standard interactions, such as Click, in code-behind (this can be quite inefficient, depending on the complexity of your UI), you can bind event listener for standard interactions to a shared handler, or you can bind the control's Command property to an ICommand implementation that describes the command logic.

To provide rich and comprehensive user experiences across command surfaces efficiently and with minimal code duplication, we recommend using the command binding features described in this topic(for standard event handling, see the individual event topics).

To bind a control to a shared command resource, you can implement the ICommand interfaces yourself, or you can build your command from either the XamlUICommand base class or one of the platform commands defined by the StandardUICommand derived class.

- The ICommand interface (Windows.UI.Xaml.Input.ICommand or System.Windows.Input.ICommand) lets you create fully customized, reusable commands across your app.

- XamlUICommand also provides this capability but simplifies development by exposing a set of built-in command properties such as the command behavior, keyboard shortcuts (access key and accelerator key), icon, label, and description.
- StandardUICommand simplifies things further by letting you choose from a set of standard platform commands with predefined properties.

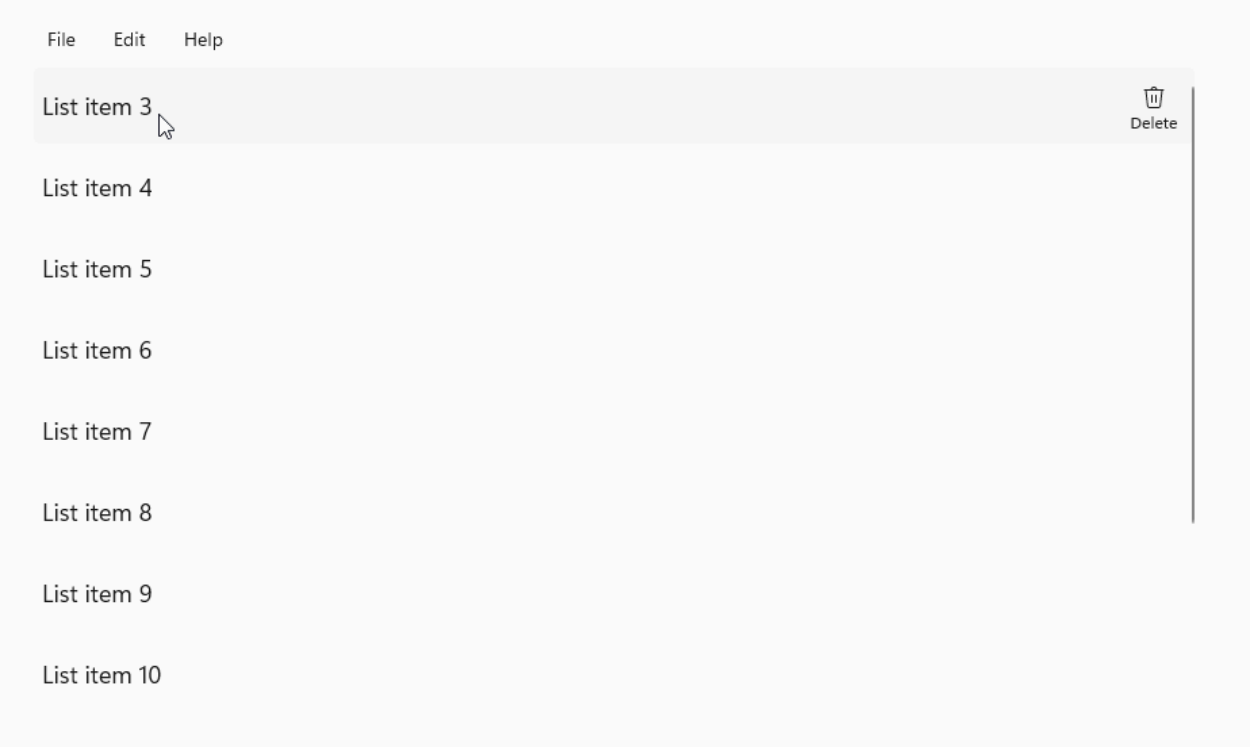
> **Important**
>
> In UWP applications, commands are implementations of either the **Windows.UI.Xaml.Input.ICommand** (C++) or the **System.Windows.Input.ICommand** (C#) interface, depending on your chosen language framework.

Command experiences using the StandardUICommand class

Derived from XamlUICommand (derived from Windows.UI.Xaml.Input.ICommand for C++ or System.Windows.Input.ICommand for C#), the StandardUICommand class exposes a set of standard platform commands with pre-defined properties such as icon, keyboard accelerator, and description.

A StandardUICommand provides a quick and consistent way to define common commands such as `Save` or `Delete`. All you have to do is provide the execute and canExecute functions.

Example



StandardUICommandSample

Expand table

Download the code for this example
UWP commanding sample (StandardUICommand)

In this example, we show how to enhance a basic ListView with a Delete item command implemented through the StandardUICommand class, while optimizing the user experience for a variety of input types using a MenuBar, Swipe control, hover buttons, and context menu.

> **Note**
>
> This sample requires the Microsoft.UI.Xaml.Controls NuGet package, a part of WinUI 2.

Xaml:

The sample UI includes a ListView of five items. The Delete StandardUICommand is bound to a MenuBarItem, a SwipeItem, an AppBarButton, and ContextFlyout menu.

XAML

```
<Page
    x:Class="StandardUICommandSample.MainPage"
```

```
    xmlns="http://schemas.microsoft.com/winfx/2006/xaml/presentation"
    xmlns:x="http://schemas.microsoft.com/winfx/2006/xaml"
    xmlns:local="using:StandardUICommandSample"
    xmlns:d="http://schemas.microsoft.com/expression/blend/2008"
    xmlns:mc="http://schemas.openxmlformats.org/markup-compatibility/2006"
    xmlns:muxcontrols="using:Microsoft.UI.Xaml.Controls"
    mc:Ignorable="d"
    Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">

    <Page.Resources>
        <Style x:Key="HorizontalSwipe"
               TargetType="ListViewItem"
               BasedOn="{StaticResource ListViewItemRevealStyle}">
            <Setter Property="Height" Value="60"/>
            <Setter Property="Padding" Value="0"/>
            <Setter Property="HorizontalContentAlignment" Value="Stretch"/>
            <Setter Property="VerticalContentAlignment" Value="Stretch"/>
            <Setter Property="BorderThickness" Value="0"/>
        </Style>
    </Page.Resources>

    <Grid Loaded="ControlExample_Loaded">
        <Grid.RowDefinitions>
            <RowDefinition Height="Auto" />
            <RowDefinition Height="Auto" />
            <RowDefinition Height="*"/>
        </Grid.RowDefinitions>

        <StackPanel Grid.Row="0"
                    Padding="10"
                    BorderThickness="0,0,0,1"
                    BorderBrush="LightBlue"
                    Background="AliceBlue">
            <TextBlock Style="{StaticResource HeaderTextBlockStyle}">
                StandardUICommand sample
            </TextBlock>
            <TextBlock Style="{StaticResource SubtitleTextBlockStyle}"
Margin="0,0,0,10">
                This sample shows how to use the StandardUICommand class to
                share a platform command and consistent user experiences
                across various controls.
            </TextBlock>
            <TextBlock Style="{StaticResource SubtitleTextBlockStyle}"
Margin="0,0,0,0">
                Specifically, we define a standard delete command and add it
                to a variety of command surfaces, all of which share a
common
                icon, label, keyboard accelerator, and description.
            </TextBlock>

                            <VisualStateManager.VisualStateGroups>
                                <VisualStateGroup x:Name="HoveringStates">
                                    <VisualState x:Name="HoverButtonsHidden"
/>
                                    <VisualState x:Name="HoverButtonsShown">
                                        <VisualState.Setters>
                                            <Setter
Target="HoverButton.Visibility"
                                                    Value="Visible" />
                                        </VisualState.Setters>
                                    </VisualState>
                                </VisualStateGroup>
                            </VisualStateManager.VisualStateGroups>
                            <SwipeControl x:Name="ListViewSwipeContainer" >
                                <SwipeControl.RightItems>
                                    <SwipeItems Mode="Execute">
                                        <SwipeItem x:Name="DeleteSwipeItem"
                                                   Background="Red"
                                                   Command="{x:Bind
Command}"
                                                   CommandParameter="{x:Bind
Text}"/>
                                    </SwipeItems>
                                </SwipeControl.RightItems>
                                <Grid VerticalAlignment="Center">
                                    <TextBlock Text="{x:Bind Text}"
                                               Margin="10"
                                               FontSize="18"
                                               HorizontalAlignment="Left"
```

```
                                                VerticalAlignment="Center"/>
                                    <AppBarButton x:Name="HoverButton"
                                                  IsTabStop="False"

HorizontalAlignment="Right"
                                                  Visibility="Collapsed"
                                                  Command="{x:Bind Command}"
                                                  CommandParameter="{x:Bind
Text}"/>
                                </Grid>
                            </SwipeControl>
                        </Grid>
                    </UserControl>
                </DataTemplate>
            </ListView.ItemTemplate>
        </ListView>
    </Grid>
</Page>
```

Code-behind

1. First, we define a `ListItemData` class that contains a text string and ICommand for each ListViewItem in our ListView.

C#

```
public class ListItemData
{
    public String Text { get; set; }
    public ICommand Command { get; set; }
}
```

2. In the MainPage class, we define a collection of `ListItemData` objects for the DataTemplate of the ListView ItemTemplate. We then populate it with an initial collection of five items (with text and associated StandardUICommand Delete).

C#

```
/// <summary>
/// ListView item collection.
/// </summary>
ObservableCollection<ListItemData> collection =
    new ObservableCollection<ListItemData>();

/// <summary>
/// Handler for the layout Grid control load event.
/// </summary>
/// <param name="sender">Source of the control loaded event</param>
/// <param name="e">Event args for the loaded event</param>
private void ControlExample_Loaded(object sender, RoutedEventArgs e)
```

```
{
    // Create the standard Delete command.
    var deleteCommand = new StandardUICommand(StandardUICommandKind.Delete);
    deleteCommand.ExecuteRequested += DeleteCommand_ExecuteRequested;

    DeleteFlyoutItem.Command = deleteCommand;

    for (var i = 0; i < 5; i++)
    {
        collection.Add(
            new ListItemData {
                Text = "List item " + i.ToString(),
                Command = deleteCommand });
    }
}

/// <summary>
/// Handler for the ListView control load event.
/// </summary>
/// <param name="sender">Source of the control loaded event</param>
/// <param name="e">Event args for the loaded event</param>
private void ListView_Loaded(object sender, RoutedEventArgs e)
{
    var listView = (ListView)sender;
    // Populate the ListView with the item collection.
    listView.ItemsSource = collection;
}
```

3. Next, we define the ICommand ExecuteRequested handler where we implement the item delete command.

C#

```
/// <summary>
/// Handler for the Delete command.
/// </summary>
/// <param name="sender">Source of the command event</param>
/// <param name="e">Event args for the command event</param>
private void DeleteCommand_ExecuteRequested(
    XamlUICommand sender, ExecuteRequestedEventArgs args)
{
    // If possible, remove specified item from collection.
    if (args.Parameter != null)
    {
        foreach (var i in collection)
        {
            if (i.Text == (args.Parameter as string))
            {
                collection.Remove(i);
                return;
            }
        }
    }
```

```
    if (ListViewRight.SelectedIndex != -1)
    {
        collection.RemoveAt(ListViewRight.SelectedIndex);
    }
}
```

4. Finally, we define handlers for various ListView events, including PointerEntered, PointerExited, and SelectionChanged events. The pointer event handlers are used to show or hide the Delete button for each item.

C#

```
/// <summary>
/// Handler for the ListView selection changed event.
/// </summary>
/// <param name="sender">Source of the selection changed event</param>
/// <param name="e">Event args for the selection changed event</param>
private void ListView_SelectionChanged(object sender,
SelectionChangedEventArgs e)
{
    if (ListViewRight.SelectedIndex != -1)
    {
        var item = collection[ListViewRight.SelectedIndex];
    }
}

/// <summary>
/// Handler for the pointer entered event.
/// Displays the delete item "hover" buttons.
/// </summary>
/// <param name="sender">Source of the pointer entered event</param>
/// <param name="e">Event args for the pointer entered event</param>
private void ListViewSwipeContainer_PointerEntered(
    object sender, PointerRoutedEventArgs e)
{
    if (e.Pointer.PointerDeviceType ==
        Windows.Devices.Input.PointerDeviceType.Mouse ||
        e.Pointer.PointerDeviceType ==
        Windows.Devices.Input.PointerDeviceType.Pen)
    {
        VisualStateManager.GoToState(
            sender as Control, "HoverButtonsShown", true);
    }
}

/// <summary>
/// Handler for the pointer exited event.
/// Hides the delete item "hover" buttons.
/// </summary>
/// <param name="sender">Source of the pointer exited event</param>
/// <param name="e">Event args for the pointer exited event</param>

private void ListViewSwipeContainer_PointerExited(
```

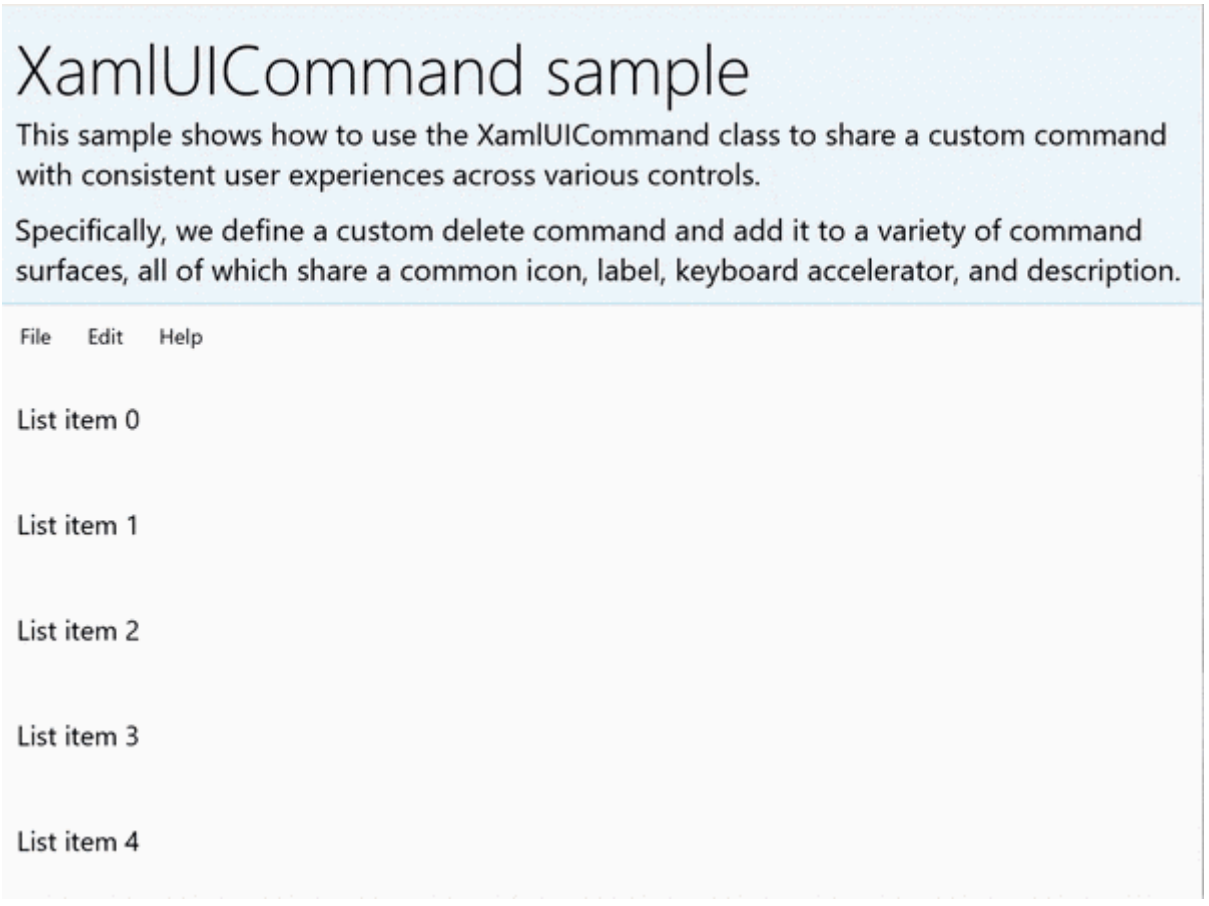
```
    object sender, PointerRoutedEventArgs e)
{
    VisualStateManager.GoToState(
        sender as Control, "HoverButtonsHidden", true);
}
```

Command experiences using the XamlUICommand class

If you need to create a command that isn't defined by the StandardUICommand class, or you'd like more control over the command appearance, the XamlUICommand class derives from the ICommand interface, adding various UI properties (such as an icon, label, description, and keyboard shortcuts), methods, and events to quickly define the UI and behavior of a custom command.

XamlUICommand lets you specify UI through the control binding, such as an icon, label, description, and keyboard shortcuts (both an access key and a keyboard accelerator), without setting the individual properties.

Example



XamlUICommandSample

Expand table

Download the code for this example
UWP commanding sample (XamlUICommand)

This example shares the Delete functionality of the previous StandardUICommand example, but shows how the XamlUICommand class lets you define a custom delete command with your own font icon, label, keyboard accelerator, and description. Like the StandardUICommand example, we enhance a basic ListView with a Delete item command implemented through the XamlUICommand class, while optimizing the user experience for a variety of input types using a MenuBar, Swipe control, hover buttons, and context menu.

Many platform controls use the XamlUICommand properties under the covers, just like our StandardUICommand example in the previous section.

> **Note**
>
> This sample requires the Microsoft.UI.Xaml.Controls NuGet package, a part of WinUI 2.

Xaml:

The sample UI includes a ListView of five items. The custom XamlUICommand CustomXamlUICommand is bound to a MenuBarItem, a SwipeItem, an AppBarButton, and ContextFlyout menu.

                                <SwipeControl.RightItems>
                                    <SwipeItems Mode="Execute">
                                        <SwipeItem x:Name="DeleteSwipeItem"
                                                   Background="Red"
                                                   Command="{x:Bind
Command}"
                                                   CommandParameter="{x:Bind
Text}"/>
                                    </SwipeItems>
                                </SwipeControl.RightItems>
                                <Grid VerticalAlignment="Center">
                                    <TextBlock Text="{x:Bind Text}"
                                               Margin="10"
                                               FontSize="18"
                                               HorizontalAlignment="Left"
```

```
                                                VerticalAlignment="Center"/>
                                        <AppBarButton x:Name="HoverButton"
                                                      IsTabStop="False"

HorizontalAlignment="Right"
                                                      Visibility="Collapsed"
                                                      Command="{x:Bind Command}"
                                                      CommandParameter="{x:Bind
Text}"/>
                                    </Grid>
                                </SwipeControl>
                            </Grid>
                        </UserControl>
                    </DataTemplate>
                </ListView.ItemTemplate>
            </ListView>
        </Grid>
</Page>
```

Code-behind

1. First, we define a `ListItemData` class that contains a text string and ICommand for each ListViewItem in our ListView.

C#

```
public class ListItemData
{
    public String Text { get; set; }
    public ICommand Command { get; set; }
}
```

2. In the MainPage class, we define a collection of `ListItemData` objects for the DataTemplate of the ListView ItemTemplate. We then populate it with an initial collection of five items (with text and associated XamlUICommand).

C#

```
ObservableCollection<ListItemData> collection = new
ObservableCollection<ListItemData>();

private void ControlExample_Loaded(object sender, RoutedEventArgs e)
{
    for (var i = 0; i < 5; i++)
    {
        collection.Add(
           new ListItemData { Text = "List item " + i.ToString(), Command =
CustomXamlUICommand });
    }
}
```

```
private void ListView_Loaded(object sender, RoutedEventArgs e)
{
    var listView = (ListView)sender;
    listView.ItemsSource = collection;
}
```

3. Next, we define the ICommand ExecuteRequested handler where we implement the item delete command.

C#

```
private void DeleteCommand_ExecuteRequested(
   XamlUICommand sender, ExecuteRequestedEventArgs args)
{
    if (args.Parameter != null)
    {
        foreach (var i in collection)
        {
            if (i.Text == (args.Parameter as string))
            {
                collection.Remove(i);
                return;
            }
        }
    }
    if (ListViewRight.SelectedIndex != -1)
    {
        collection.RemoveAt(ListViewRight.SelectedIndex);
    }
}
```

4. Finally, we define handlers for various ListView events, including PointerEntered, PointerExited, and SelectionChanged events. The pointer event handlers are used to show or hide the Delete button for each item.

C#

```
private void ListView_SelectionChanged(object sender,
SelectionChangedEventArgs e)
{
    if (ListViewRight.SelectedIndex != -1)
    {
        var item = collection[ListViewRight.SelectedIndex];
    }
}

private void ListViewSwipeContainer_PointerEntered(object sender,
PointerRoutedEventArgs e)
{
    if (e.Pointer.PointerDeviceType ==
```

```
        Windows.Devices.Input.PointerDeviceType.Mouse ||
        e.Pointer.PointerDeviceType ==
Windows.Devices.Input.PointerDeviceType.Pen)
    {
        VisualStateManager.GoToState(sender as Control, "HoverButtonsShown",
true);
    }
}

private void ListViewSwipeContainer_PointerExited(object sender,
PointerRoutedEventArgs e)
{
    VisualStateManager.GoToState(sender as Control, "HoverButtonsHidden",
true);
}
```

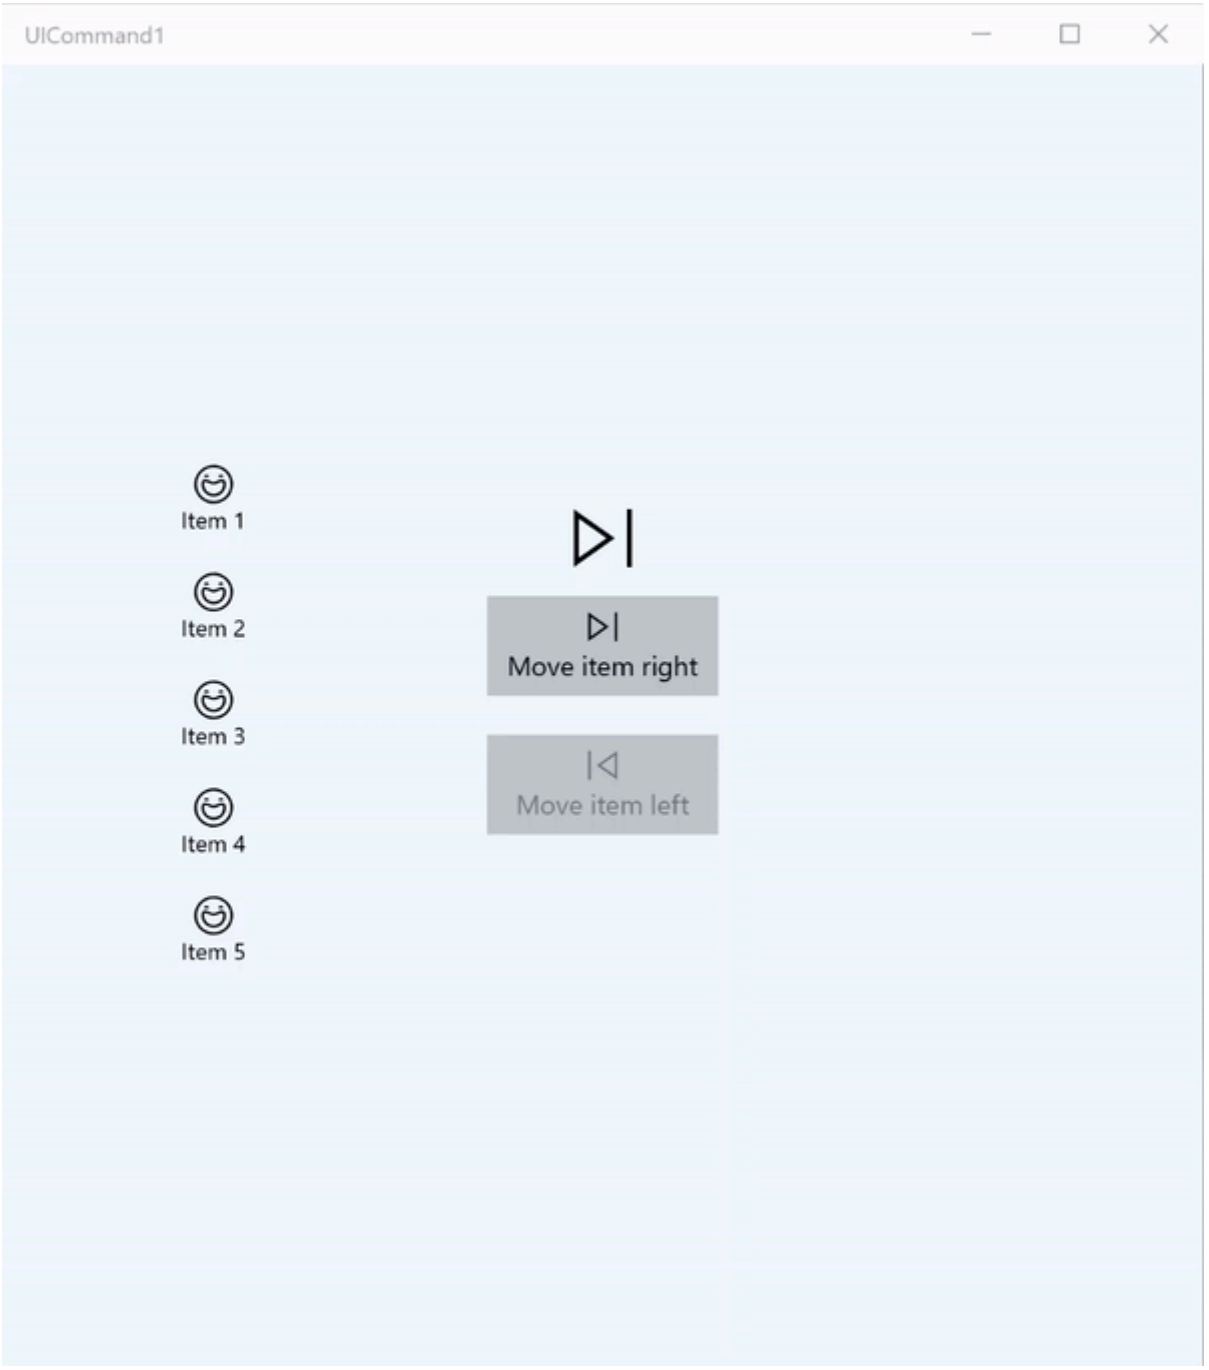
Command experiences using the ICommand interface

Standard UWP controls (button, list, selection, calendar, predictive text) provide the basis for many common command experiences. For a complete list of control types, see Controls and patterns for Windows apps.

The most basic way to support a structured commanding experience is to define an implementation of the ICommand interface (Windows.UI.Xaml.Input.ICommand for C++ or System.Windows.Input.ICommand for C#). This ICommand instance can then be bound to controls such as buttons.

> **Note**
>
> In some cases, it might be just as efficient to bind a method to the Click event and a property to the IsEnabled property.

Example



ICommand example

Expand table

Download the code for this example
UWP commanding sample (ICommand)

In this basic example, we demonstrate how a single command can be invoked with a button click, a keyboard accelerator, and rotating a mouse wheel.

We use two ListViews, one populated with five items and the other empty, and two buttons, one for moving items from the ListView on the left to the ListView on the right, and the other for moving items from the right to the left. Each button is bound to a

corresponding command (ViewModel.MoveRightCommand and ViewModel.MoveLeftCommand, respectively), and are enabled and disabled automatically based on the number of items in their associated ListView.

The following XAML code defines the UI for our example.

XAML

```
<Page
    x:Class="UICommand1.View.MainPage"
    xmlns="http://schemas.microsoft.com/winfx/2006/xaml/presentation"
    xmlns:x="http://schemas.microsoft.com/winfx/2006/xaml"
    xmlns:vm="using:UICommand1.ViewModel"
    xmlns:d="http://schemas.microsoft.com/expression/blend/2008"
    xmlns:mc="http://schemas.openxmlformats.org/markup-compatibility/2006"
    mc:Ignorable="d"
    Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">

    <Page.Resources>
        <vm:OpacityConverter x:Key="opaque" />
    </Page.Resources>

    <Grid Name="ItemGrid"
          Background="AliceBlue"
          PointerWheelChanged="Page_PointerWheelChanged">
        <Grid.ColumnDefinitions>
            <ColumnDefinition Width="*"/>
            <ColumnDefinition Width="2*"/>
            <ColumnDefinition Width="*"/>
        </Grid.ColumnDefinitions>
        <ListView Grid.Column="0" VerticalAlignment="Center"
                  x:Name="CommandListView"
                  ItemsSource="{x:Bind Path=ViewModel.ListItemLeft}"
                  SelectionMode="None" IsItemClickEnabled="False"
                  HorizontalAlignment="Right">
            <ListView.ItemTemplate>
                <DataTemplate x:DataType="vm:ListItemData">
                    <Grid VerticalAlignment="Center">
                        <AppBarButton Label="{x:Bind ListItemText}">
                            <AppBarButton.Icon>
                                <SymbolIcon Symbol="{x:Bind ListItemIcon}"/>
                            </AppBarButton.Icon>
                        </AppBarButton>
                    </Grid>
                </DataTemplate>
            </ListView.ItemTemplate>
        </ListView>
        <Grid Grid.Column="1" Margin="0,0,0,0"
              HorizontalAlignment="Center"
              VerticalAlignment="Center">
            <Grid.RowDefinitions>
                <RowDefinition Height="*"/>
                <RowDefinition Height="*"/>
```

```
                <RowDefinition Height="*"/>
            </Grid.RowDefinitions>
            <StackPanel Grid.Row="1">
                <FontIcon FontFamily="{StaticResource
SymbolThemeFontFamily}"

                        </AppBarButton>
                    </Grid>
                </DataTemplate>
            </ListView.ItemTemplate>
        </ListView>
    </Grid>
</Page>
```

Here's the code-behind for the preceding UI.

In code-behind, we connect to our view model that contains our command code. In addition, we define a handler for input from the mouse wheel, which also connects our command code.

C#

```
using Windows.UI.Xaml;
using Windows.UI.Xaml.Input;
using Windows.UI.Xaml.Controls;
using UICommand1.ViewModel;
using Windows.System;
using Windows.UI.Core;

namespace UICommand1.View
{
    /// <summary>
    /// An empty page that can be used on its own or navigated to within a
Frame.
    /// </summary>
    public sealed partial class MainPage : Page
    {
        // Reference to our view model.
        public UICommand1ViewModel ViewModel { get; set; }

        // Initialize our view and view model.
        public MainPage()
        {
            this.InitializeComponent();
            ViewModel = new UICommand1ViewModel();
        }

        /// <summary>
        /// Handle mouse wheel input and assign our
        /// commands to appropriate direction of rotation.
        /// </summary>
```

```
        /// <param name="sender"></param>
        /// <param name="e"></param>
        private void Page_PointerWheelChanged(object sender,
PointerRoutedEventArgs e)
        {
            var props = e.GetCurrentPoint(sender as UIElement).Properties;

            // Require CTRL key and accept only vertical mouse wheel
movement
            // to eliminate accidental wheel input.
            if ((Window.Current.CoreWindow.GetKeyState(VirtualKey.Control)
!=
                CoreVirtualKeyStates.None) && !props.IsHorizontalMouseWheel)
            {
                bool delta = props.MouseWheelDelta < 0 ? true : false;

                switch (delta)
                {
                    case true:
                        ViewModel.MoveRight();
                        break;
                    case false:
                        ViewModel.MoveLeft();
                        break;
                    default:
                        break;
                }
            }
        }
    }
}
```

Here's the code from our view model

Our view model is where we define the execution details for the two commands in our app, populate one ListView, and provide an opacity value converter for hiding or displaying some additional UI based on the item count of each ListView.

C#

```
using System;
using System.Collections.ObjectModel;
using System.ComponentModel;
using Windows.UI.Xaml.Controls;
using Windows.UI.Xaml.Data;

namespace UICommand1.ViewModel
{
    /// <summary>
    /// UI properties for our list items.
    /// </summary>
    public class ListItemData
```

```
    {
        /// <summary>
        /// Gets and sets the list item content string.
        /// </summary>
        public string ListItemText { get; set; }
        /// <summary>
        /// Gets and sets the list item icon.
        /// </summary>
        public Symbol ListItemIcon { get; set; }
    }

    /// <summary>
    /// View Model that sets up a command to handle invoking the move item
buttons.
    /// </summary>
    public class UICommand1ViewModel
    {
        /// <summary>
        /// The command to invoke when the Move item left button is pressed.
        /// </summary>
        public RelayCommand MoveLeftCommand { get; private set; }

        /// <summary>
        /// The command to invoke when the Move item right button is
pressed.
        /// </summary>
        public RelayCommand MoveRightCommand { get; private set; }

        // Item collections
        public ObservableCollection<ListItemData> ListItemLeft { get; } =
           new ObservableCollection<ListItemData>();
        public ObservableCollection<ListItemData> ListItemRight { get; } =
           new ObservableCollection<ListItemData>();

        public ListItemData listItem;

        /// <summary>
        /// Sets up a command to handle invoking the move item buttons.
        /// </summary>
        public UICommand1ViewModel()
        {
            MoveLeftCommand =
               new RelayCommand(new Action(MoveLeft),
CanExecuteMoveLeftCommand);
            MoveRightCommand =
               new RelayCommand(new Action(MoveRight),
CanExecuteMoveRightCommand);

            LoadItems();
        }

        /// <summary>
        ///  Populate our list of items.
        /// </summary>
        public void LoadItems()
```

```
        {
            for (var x = 0; x <= 4; x++)
            {
                listItem = new ListItemData();
                listItem.ListItemText = "Item " + (ListItemLeft.Count +
1).ToString();
                listItem.ListItemIcon = Symbol.Emoji;
                ListItemLeft.Add(listItem);
            }
        }

        /// <summary>
        /// Move left command valid when items present in the list on right.
        /// </summary>
        /// <returns>True, if count is greater than 0.</returns>
        private bool CanExecuteMoveLeftCommand()
        {

        /// The command implementation to execute when the Move item right
button is pressed.
        /// </summary>
        public void MoveRight()
        {
            if (ListItemLeft.Count > 0)
            {
                listItem = new ListItemData();
                ListItemRight.Add(listItem);
                listItem.ListItemText = "Item " +
ListItemRight.Count.ToString();
                listItem.ListItemIcon = Symbol.Emoji;
                ListItemLeft.RemoveAt(ListItemLeft.Count - 1);
                MoveRightCommand.RaiseCanExecuteChanged();
                MoveLeftCommand.RaiseCanExecuteChanged();
            }
        }

        /// <summary>
        /// The command implementation to execute when the Move item left
button is pressed.
        /// </summary>
        public void MoveLeft()
        {
            if (ListItemRight.Count > 0)
```

```
            {
                listItem = new ListItemData();
                ListItemLeft.Add(listItem);
                listItem.ListItemText = "Item " +
ListItemLeft.Count.ToString();
                listItem.ListItemIcon = Symbol.Emoji;
                ListItemRight.RemoveAt(ListItemRight.Count - 1);
                MoveRightCommand.RaiseCanExecuteChanged();
                MoveLeftCommand.RaiseCanExecuteChanged();
            }
        }

        /// <summary>
        /// Views subscribe to this event to get notified of property
updates.
        /// </summary>
        public event PropertyChangedEventHandler PropertyChanged;

        /// <summary>
        /// Notify subscribers of updates to the named property
        /// </summary>
        /// <param name="propertyName">The full, case-sensitive, name of a
property.</param>
        protected void NotifyPropertyChanged(string propertyName)
        {
            PropertyChangedEventHandler handler = this.PropertyChanged;
            if (handler != null)
            {
                PropertyChangedEventArgs args = new
PropertyChangedEventArgs(propertyName);
                handler(this, args);
            }
        }
    }

    /// <summary>
    /// Convert a collection count to an opacity value of 0.0 or 1.0.
    /// </summary>
    public class OpacityConverter : IValueConverter
    {
        /// <summary>
        /// Converts a collection count to an opacity value of 0.0 or 1.0.
        /// </summary>
        /// <param name="value">The count passed in</param>
        /// <param name="targetType">Ignored.</param>
        /// <param name="parameter">Ignored</param>
        /// <param name="language">Ignored</param>
        /// <returns>1.0 if count > 0, otherwise returns 0.0</returns>
        public object Convert(object value, Type targetType, object
parameter, string language)
        {
            return ((int)value > 0 ? 1.0 : 0.0);
        }

        /// <summary>
```

```
        /// Not used, converter is not intended for two-way binding.
        /// </summary>
        /// <param name="value">Ignored</param>
        /// <param name="targetType">Ignored</param>
        /// <param name="parameter">Ignored</param>
        /// <param name="language">Ignored</param>
        /// <returns></returns>
        public object ConvertBack(object value, Type targetType, object
parameter, string language)
        {
            throw new NotImplementedException();
        }
    }
}
```

Finally, here's our implementation of the ICommand interface

Here, we define a command that implements the ICommand interface and simply relays its functionality to other objects.

C#

```
using System;
using System.Windows.Input;

namespace UICommand1
{
    /// <summary>
    /// A command whose sole purpose is to relay its functionality
    /// to other objects by invoking delegates.
    /// The default return value for the CanExecute method is 'true'.
    /// <see cref="RaiseCanExecuteChanged"/> needs to be called whenever
    /// <see cref="CanExecute"/> is expected to return a different value.
    /// </summary>
    public class RelayCommand : ICommand
    {
        private readonly Action _execute;
        private readonly Func<bool> _canExecute;

        /// <summary>
        /// Raised when RaiseCanExecuteChanged is called.
        /// </summary>
        public event EventHandler CanExecuteChanged;

        /// <summary>
        /// Creates a new command that can always execute.
        /// </summary>
        /// <param name="execute">The execution logic.</param>
        public RelayCommand(Action execute)
            : this(execute, null)
        {
        }
```

```
        /// <summary>
        /// Creates a new command.
        /// </summary>
        /// <param name="execute">The execution logic.</param>
        /// <param name="canExecute">The execution status logic.</param>
        public RelayCommand(Action execute, Func<bool> canExecute)
        {
            if (execute == null)
                throw new ArgumentNullException("execute");
            _execute = execute;
            _canExecute = canExecute;
        }

        /// <summary>
        /// Determines whether this <see cref="RelayCommand"/> can execute
in its current state.
        /// </summary>
        /// <param name="parameter">
        /// Data used by the command. If the command does not require
        /// data to be passed, this object can be set to null.
        /// </param>
        /// <returns>true if this command can be executed; otherwise, false.
</returns>
        public bool CanExecute(object parameter)
        {
            return _canExecute == null ? true : _canExecute();
        }

        /// <summary>
        /// Executes the <see cref="RelayCommand"/> on the current command
target.
        /// </summary>
        /// <param name="parameter">
        /// Data used by the command. If the command does not require
        /// data to be passed, this object can be set to null.
        /// </param>
        public void Execute(object parameter)
        {
            _execute();
        }

        /// <summary>
        /// Method used to raise the <see cref="CanExecuteChanged"/> event
        /// to indicate that the return value of the <see
cref="CanExecute"/>
        /// method has changed.
        /// </summary>
        public void RaiseCanExecuteChanged()
        {
            var handler = CanExecuteChanged;
            if (handler != null)
            {
                handler(this, EventArgs.Empty);
            }
        }
```

```
    }
}
```

Summary

The Universal Windows Platform provides a robust and flexible commanding system that lets you build apps that share and manage commands across control types, devices, and input types.

Use the following approaches when building commands for your Windows apps:

- Listen for and handle events in XAML/code-behind
- Bind to an event handling method such as Click
- Define your own ICommand implementation
- Create XamlUICommand objects with your own values for a pre-defined set of properties
- Create StandardUICommand objects with a set of pre-defined platform properties and values

Next steps

For a complete example that demonstrates a XamlUICommand and StandardUICommand implementation, see the WinUI 2 Gallery sample.

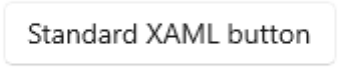
Buttons

Article • 02/26/2025

A button gives the user a way to trigger an immediate action. Some buttons are specialized for particular tasks, such as navigation, repeated actions, or presenting menus.



The Extensible Application Markup Language (XAML) framework provides a standard button control as well as several specialized button controls.

Expand table

Control	Description
Button	A button that initiates an immediate action. Can be used with a Click event or Command binding.
RepeatButton	A button that raises a Click event continuously while pressed.
HyperlinkButton	A button that's styled like a hyperlink and used for navigation. For more info about hyperlinks, see Hyperlinks.
DropDownButton	A button with a chevron to open an attached flyout.
SplitButton	A button with two sides. One side initiates an action, and the other side opens a menu.
ToggleSplitButton	A toggle button with two sides. One side toggles on/off, and the other side opens a menu.
ToggleButton	A button that can be on or off.

Is this the right control?

Use a **Button** control to let the user initiate an immediate action, such as submitting a form.

Don't use a **Button** control when the action is to navigate to another page; instead, use a HyperlinkButton control. For more info about hyperlinks, see Hyperlinks.

> **ⓘ Important**
>
> For wizard navigation, use buttons labeled *Back* and *Next*. For other types of backwards navigation or navigation to an upper level, use a **back button**.

Use a **RepeatButton** control when the user might want to trigger an action repeatedly. For example, use a **RepeatButton** control to increment or decrement a value in a counter.

Use a **DropDownButton** control when the button has a flyout that contains more options. The default chevron provides a visual indication that the button includes a flyout.

Use a **SplitButton** control when you want the user to be able to initiate an immediate action or choose from additional options independently.

Use a **ToggleButton** control when you want the user to be able to immediately switch between two mutually exclusive states, and a button is the best fit for your UI needs. Unless your UI benefits from a button, it might be a better choice to use an AppBarToggleButton, CheckBox, RadioButton, or ToggleSwitch.

Recommendations

- Make sure the purpose and state of a button are clear to the user.
- When there are multiple buttons for the same decision (such as in a confirmation dialog), present the commit buttons in this order, where [Do it] and [Don't do it] are specific responses to the main instruction:
  - OK/[Do it]/Yes
    - [Don't do it]/No
    - Cancel
- Expose only one or two buttons to the user at a time, for example, **Accept** and **Cancel**. If you need to expose more actions to the user, consider using checkboxes or radio buttons from which the user can select actions, with a single command button to trigger those actions.
- For an action that needs to be available across multiple pages within your app, instead of duplicating a button on multiple pages, consider using a bottom app bar.

Button text

A button's content is usually text. When you design that text, use the following recommendations:

- Use a concise, specific, self-explanatory text that clearly describes the action that the button performs. Usually button text is a single word that is a verb.
- Use the default font, unless your brand guidelines tell you to use something different.
- For shorter text, avoid narrow command buttons by using a minimum button width of 120px.
- For longer text, avoid wide command buttons by limiting text to a maximum length of 26 characters.
- If the button's text content is dynamic (that is, it is localized), consider how the button will be resized and what will happen to controls around it.

Expand table

Need to fix: Buttons with overflowing text.	
Option 1: Increase button width, stack buttons, and wrap if text length is greater than 26 characters.	Option 2: Increase button height, and wrap text.	

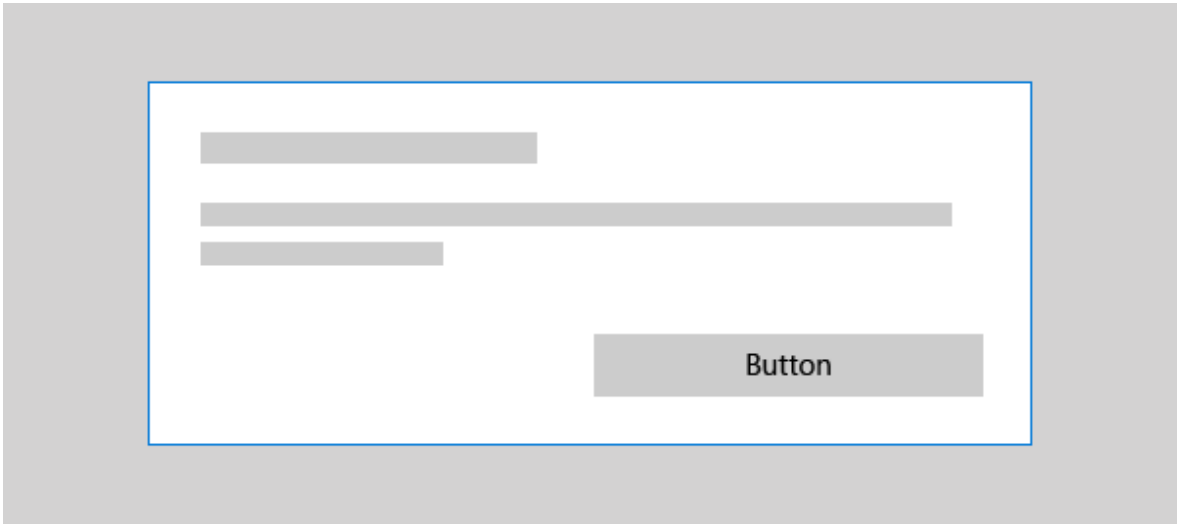
Recommended single-button layout

If your layout requires only one button, it should be either left- or right-aligned based on its container context.

- Dialogs with only one button should **right-align** the button. If your dialog contains only one button, ensure that the button performs the safe, nondestructive action. If you use ContentDialog and specify a single button, it will be automatically right-aligned.



- If your button appears within a container UI (for example, within a toast notification, a flyout, or a list view item), you should **right-align** the button within the container.

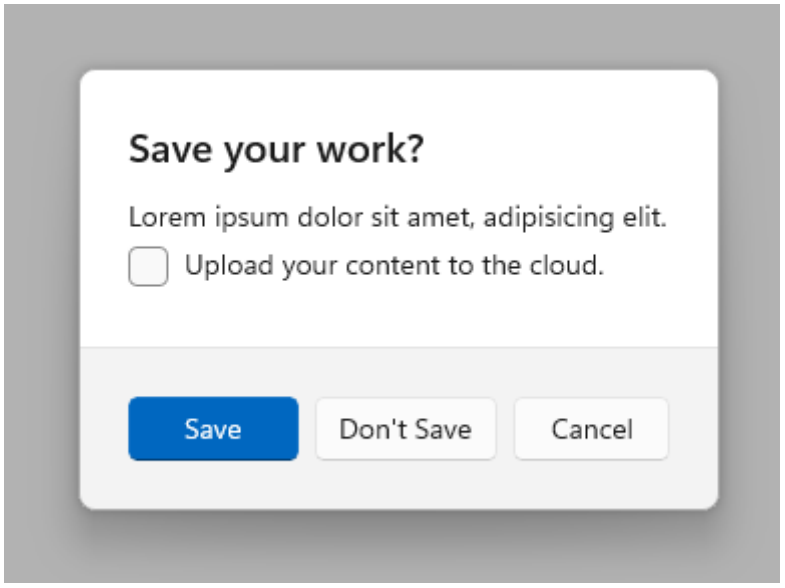
- In pages that contain a single button (for example, an **Apply** button at the bottom of a settings page), you should **left-align** the button. This ensures that the button aligns with the rest of the page content.

Back buttons

The back button is a system-provided UI element that enables backward navigation through either the back stack or navigation history of the user. You don't have to create your own back button, but you might have to do some work to enable a good backwards navigation experience. For more info, see Navigation history and backwards navigation for Windows apps.

Examples

This example uses three buttons, **Save**, **Don't Save**, and **Cancel**, in a dialog that asks users if they want to save their work.



Create a button

✔ **Important APIs:** Button class, Click event, Command property, Content property

Open the WinUI 3 Gallery app and see the Buttons in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

This example shows a button that responds to a click.

Create the button in XAML.

XAML

```
<Button Content="Subscribe" Click="SubscribeButton_Click"/>
```

Or create the button in code.

C#

```
Button subscribeButton = new Button();
subscribeButton.Content = "Subscribe";
subscribeButton.Click += SubscribeButton_Click;

// Add the button to a parent container in the visual tree.
stackPanel1.Children.Add(subscribeButton);
```

Handle the Click event.

C#

```
private async void SubscribeButton_Click(object sender, RoutedEventArgs e)
{
    // Call app specific code to subscribe to the service. For example:
    ContentDialog subscribeDialog = new ContentDialog
    {
        Title = "Subscribe to App Service?",
        Content = "Listen, watch, and play in high definition for only
$9.99/month. Free to try, cancel anytime.",
        CloseButtonText = "Not Now",
        PrimaryButtonText = "Subscribe",
        SecondaryButtonText = "Try it"
    };

    ContentDialogResult result = await subscribeDialog.ShowAsync();
}
```

Button interaction

When you tap a **Button** control with a finger or stylus, or press a left mouse button while the pointer is over it, the button raises the Click event. If a button has keyboard focus, pressing the Enter key or the Spacebar also raises the **Click** event.

You generally can't handle low-level PointerPressed events on a **Button** object because it has the **Click** behavior instead. For more info, see Events and routed events overview.

You can change how a button raises the **Click** event by changing the ClickMode property. The default value of **ClickMode** is **Release**, but you also can set a button's **ClickMode** value to **Hover** or **Press**. If **ClickMode** is **Hover**, the **Click** event can't be raised by using the keyboard or touch.

Button content

Button is a content control of the ContentControl class. Its XAML content property is Content, which enables a syntax like this for XAML: `<Button>A button's content</Button>`. You can set any object as the button's content. If the content is a UIElement object, it is rendered in the button. If the content is another type of object, its string representation is shown in the button.

A button's content is usually text. When you design that text, follow the Button text recommendations listed previously.

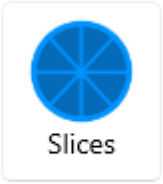
You can also customize visuals that make up the button's appearance. For example, you could replace the text with an icon, or use an icon in addition to text.

Here, a **StackPanel** that contains an image and text is set as the content of a button.

XAML

```
<Button x:Name="Button2" Click="Button_Click" Width="80" Height="90">
    <StackPanel>
        <Image Source="/Assets/Slices.png" Height="52"/>
        <TextBlock Text="Slices" Foreground="Black"
HorizontalAlignment="Center"/>
    </StackPanel>
</Button>
```

The button looks like this.



Create a repeat button

✔ **Important APIs:** RepeatButton class, Click event, Content property

Open the WinUI 3 Gallery app and see the RepeatButton in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

A RepeatButton control is a button that raises Click events repeatedly from the time it's pressed until it's released. Set the Delay property to specify the time that the **RepeatButton** control waits after it is pressed before it starts repeating the click action. Set the Interval property to specify the time between repetitions of the click action. Times for both properties are specified in milliseconds.

The following example shows two **RepeatButton** controls whose respective **Click** events are used to increase and decrease the value shown in a text block.

XAML

```
<StackPanel>
    <RepeatButton Width="100" Delay="500" Interval="100"
Click="Increase_Click">Increase</RepeatButton>
    <RepeatButton Width="100" Delay="500" Interval="100"
Click="Decrease_Click">Decrease</RepeatButton>
    <TextBlock x:Name="clickTextBlock" Text="Number of Clicks:" />
</StackPanel>
```

C#

```
private static int _clicks = 0;
private void Increase_Click(object sender, RoutedEventArgs e)
{
    _clicks += 1;
```

```
    clickTextBlock.Text = "Number of Clicks: " + _clicks;
}

private void Decrease_Click(object sender, RoutedEventArgs e)
{
    if(_clicks > 0)
    {
        _clicks -= 1;
        clickTextBlock.Text = "Number of Clicks: " + _clicks;
    }
}
```

Create a drop down button

✔ **Important APIs**: DropDownButton class, Flyout property

Open the WinUI 3 Gallery app and see the DropdownButton in action

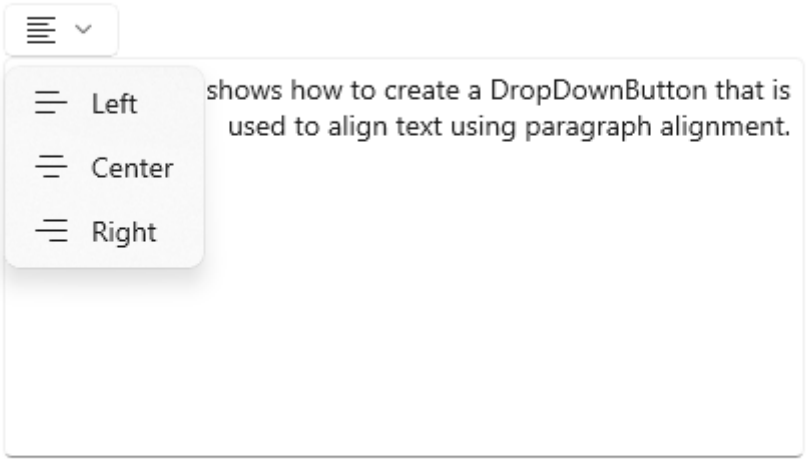
> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

A DropDownButton is a button that shows a chevron as a visual indicator that it has an attached flyout that contains more options. It has the same behavior as a standard **Button** control with a flyout; only the appearance is different.

The drop down button inherits the **Click** event, but you typically don't use it. Instead, you use the Flyout property to attach a flyout and invoke actions by using menu options in the flyout. The flyout opens automatically when the button is clicked. Be sure to specify the Placement property of your flyout to ensure the desired placement in relation to the button. The default placement algorithm might not produce the intended placement in all situations. For more info about flyouts, see Flyouts and Menu flyout and menu bar.

Example - Drop down button

This example shows how to create a drop down button with a flyout that contains commands for paragraph alignment in a **RichEditBox** control. (For more info and code, see Rich edit box).



XAML

```
<DropDownButton ToolTipService.ToolTip="Alignment">
    <TextBlock FontFamily="Segoe MDL2 Assets" FontSize="14"
Text="&#xE8E4;"/>
    <DropDownButton.Flyout>
        <MenuFlyout Placement="BottomEdgeAlignedLeft">
            <MenuFlyoutItem Text="Left" Icon="AlignLeft" Tag="left"
                            Click="AlignmentMenuFlyoutItem_Click"/>
            <MenuFlyoutItem Text="Center" Icon="AlignCenter" Tag="center"
                            Click="AlignmentMenuFlyoutItem_Click"/>
            <MenuFlyoutItem Text="Right" Icon="AlignRight" Tag="right"
                            Click="AlignmentMenuFlyoutItem_Click"/>
        </MenuFlyout>
    </DropDownButton.Flyout>
</DropDownButton>
```

C#

```
private void AlignmentMenuFlyoutItem_Click(object sender, RoutedEventArgs e)
{
    var option = ((MenuFlyoutItem)sender).Tag.ToString();

    Windows.UI.Text.ITextSelection selectedText = editor.Document.Selection;
    if (selectedText != null)
    {
        // Apply the alignment to the selected paragraphs.
        var paragraphFormatting = selectedText.ParagraphFormat;
        if (option == "left")
        {
            paragraphFormatting.Alignment =
Windows.UI.Text.ParagraphAlignment.Left;
        }
        else if (option == "center")
        {
```

```
            paragraphFormatting.Alignment =
Windows.UI.Text.ParagraphAlignment.Center;
        }
        else if (option == "right")
        {
            paragraphFormatting.Alignment =
Windows.UI.Text.ParagraphAlignment.Right;
        }
    }
}
```

Create a split button

✔ **Important APIs**: SplitButton class, Click event, Flyout property

Open the WinUI 3 Gallery app and see the SplitButton in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

A SplitButton control has two parts that can be invoked separately. One part behaves like a standard button and invokes an immediate action. The other part invokes a flyout that contains additional options that the user can choose from.

> **Note**
>
> When invoked with touch, the split button behaves as a drop down button; both halves of the button invoke the flyout. With other methods of input, a user can invoke either half of the button separately.

The typical behavior for a split button is:

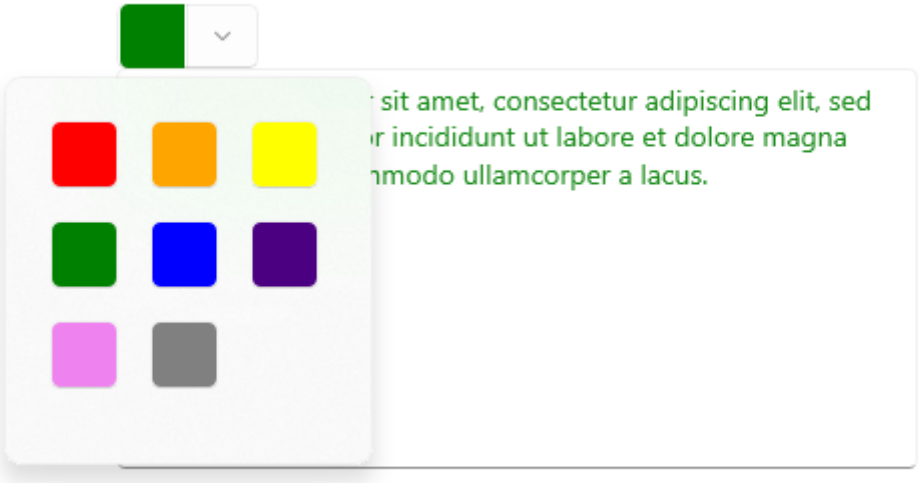
- When the user clicks the button part, handle the **Click** event to invoke the option that's currently selected in the drop down.
- When the drop down is open, handle invocation of the items in the drop down to both change which option is selected, and then invoke it. It's important to invoke the flyout item because the button **Click** event doesn't occur when using touch.

> **Tip**

There are many ways to put items in the drop down and handle their invocation. If you use a **ListView** or **GridView**, one way is to handle the **SelectionChanged** event. If you do this, set SingleSelectionFollowsFocus to **false**. This lets users navigate the options using a keyboard without invoking the item on each change.

Example - Split button

This example shows how to create a split button that is used to change the foreground color of selected text in a **RichEditBox** control. (For more info and code, see Rich edit box). Split button's flyout uses BottomEdgeAlignedLeft as the default value for its Placement property. You can't override this value.



XAML

```
<SplitButton ToolTipService.ToolTip="Foreground color"
             Click="BrushButtonClick">
    <Border x:Name="SelectedColorBorder" Width="20" Height="20"/>
    <SplitButton.Flyout>
        <Flyout x:Name="BrushFlyout">
            <!-- Set SingleSelectionFollowsFocus="False"
                 so that keyboard navigation works correctly. -->
            <GridView ItemsSource="{x:Bind ColorOptions}"
                      SelectionChanged="BrushSelectionChanged"
                      SingleSelectionFollowsFocus="False"
                      SelectedIndex="0" Padding="0">
                <GridView.ItemTemplate>
                    <DataTemplate>
                        <Rectangle Fill="{Binding}" Width="20" Height="20"/>
                    </DataTemplate>
                </GridView.ItemTemplate>
                <GridView.ItemContainerStyle>
```

```
                    <Style TargetType="GridViewItem">
                        <Setter Property="Margin" Value="2"/>
                        <Setter Property="MinWidth" Value="0"/>
                        <Setter Property="MinHeight" Value="0"/>
                    </Style>
                </GridView.ItemContainerStyle>
            </GridView>
        </Flyout>
    </SplitButton.Flyout>
</SplitButton>
```

C#

```
public sealed partial class MainPage : Page
{
    // Color options that are bound to the grid in the split button flyout.
    private List<SolidColorBrush> ColorOptions = new List<SolidColorBrush>
();
    private SolidColorBrush CurrentColorBrush = null;

    public MainPage()
    {
        this.InitializeComponent();

        // Add color brushes to the collection.
        ColorOptions.Add(new SolidColorBrush(Colors.Black));
        ColorOptions.Add(new SolidColorBrush(Colors.Red));
        ColorOptions.Add(new SolidColorBrush(Colors.Orange));
        ColorOptions.Add(new SolidColorBrush(Colors.Yellow));
        ColorOptions.Add(new SolidColorBrush(Colors.Green));
        ColorOptions.Add(new SolidColorBrush(Colors.Blue));
        ColorOptions.Add(new SolidColorBrush(Colors.Indigo));
        ColorOptions.Add(new SolidColorBrush(Colors.Violet));
        ColorOptions.Add(new SolidColorBrush(Colors.White));
    }

    private void BrushButtonClick(object sender, object e)
    {
        // When the button part of the split button is clicked,
        // apply the selected color.
        ChangeColor();
    }

    private void BrushSelectionChanged(object sender,
SelectionChangedEventArgs e)
    {
        // When the flyout part of the split button is opened and the user
selects
        // an option, set their choice as the current color, apply it, then
close the flyout.
        CurrentColorBrush = (SolidColorBrush)e.AddedItems[0];
        SelectedColorBorder.Background = CurrentColorBrush;
        ChangeColor();
```

```
            BrushFlyout.Hide();
        }

        private void ChangeColor()
        {
            // Apply the color to the selected text in a RichEditBox.
            Windows.UI.Text.ITextSelection selectedText =
editor.Document.Selection;
            if (selectedText != null)
            {
                Windows.UI.Text.ITextCharacterFormat charFormatting =
selectedText.CharacterFormat;
                charFormatting.ForegroundColor = CurrentColorBrush.Color;
                selectedText.CharacterFormat = charFormatting;
            }
        }
}
```

Create a toggle split button

✓ **Important APIs**: ToggleSplitButton class, IsCheckedChanged event, IsChecked property

Open the WinUI 3 Gallery app and see the ToggleSplitButton in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

A ToggleSplitButton control has two parts that can be invoked separately. One part behaves like a toggle button that can be on or off. The other part invokes a flyout that contains additional options that the user can choose from.

A toggle split button is typically used to enable or disable a feature when the feature has multiple options that the user can choose from. For example, in a document editor, it could be used to turn lists on or off, while the drop down is used to choose the style of the list.

Note

When invoked with touch, the toggle split button behaves as a drop down button. With other methods of input, a user can toggle and invoke the two halves of the button separately. With touch, both halves of the button invoke the flyout.

Therefore, you must include an option in your flyout content to toggle the button on or off.

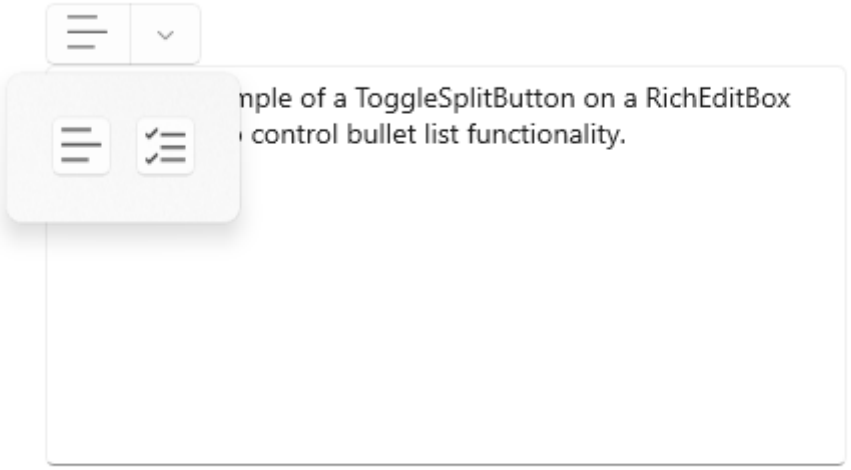
Differences with ToggleButton

Unlike ToggleButton, **ToggleSplitButton** does not have an indeterminate state. As a result, you should keep in mind these differences:

- **ToggleSplitButton** does not have an **IsThreeState** property or **Indeterminate** event.
- The ToggleSplitButton.IsChecked property is just a Boolean, not a **Nullable<bool>**.
- **ToggleSplitButton** has only the IsCheckedChanged event; it does not have separate **Checked** and **Unchecked** events.

Example - Toggle split button

The following example shows how a toggle split button could be used to turn list formatting on or off, and change the style of the list, in a **RichEditBox** control. (For more info and code, see Rich edit box). The flyout of the toggle split button uses BottomEdgeAlignedLeft as the default value for its Placement property. You can't override this value.



XAML

```
<ToggleSplitButton x:Name="ListButton"
                   ToolTipService.ToolTip="List style"
                   Click="ListButton_Click"
                   IsCheckedChanged="ListStyleButton_IsCheckedChanged">
```

```
    <TextBlock FontFamily="Segoe MDL2 Assets" FontSize="14"
Text="&#xE8FD;"/>
    <ToggleSplitButton.Flyout>
        <Flyout>
            <ListView x:Name="ListStylesListView"
                      SelectionChanged="ListStylesListView_SelectionChanged"
                      SingleSelectionFollowsFocus="False">
                <StackPanel Tag="bullet" Orientation="Horizontal">
                    <FontIcon FontFamily="Segoe MDL2 Assets"
Glyph="&#xE7C8;"/>
                    <TextBlock Text="Bullet" Margin="8,0"/>
                </StackPanel>
                <StackPanel Tag="alpha" Orientation="Horizontal">
                    <TextBlock Text="A" FontSize="24" Margin="2,0"/>
                    <TextBlock Text="Alpha" Margin="8"/>
                </StackPanel>
                <StackPanel Tag="numeric" Orientation="Horizontal">
                    <FontIcon FontFamily="Segoe MDL2 Assets"
Glyph="&#xF146;"/>
                    <TextBlock Text="Numeric" Margin="8,0"/>
                </StackPanel>
                <TextBlock Tag="none" Text="None" Margin="28,0"/>
            </ListView>
        </Flyout>
    </ToggleSplitButton.Flyout>
</ToggleSplitButton>
```

C#

```
private void ListStyleButton_IsCheckedChanged(ToggleSplitButton sender,
ToggleSplitButtonIsCheckedChangedEventArgs args)
{
    // Use the toggle button to turn the selected list style on or off.
    if (((ToggleSplitButton)sender).IsChecked == true)
    {
        // On. Apply the list style selected in the drop down to the
selected text.
        var listStyle = ((FrameworkElement)
(ListStylesListView.SelectedItem)).Tag.ToString();
        ApplyListStyle(listStyle);
    }
    else
    {
        // Off. Make the selected text not a list,
        // but don't change the list style selected in the drop down.
        ApplyListStyle("none");
    }
}

private void ListStylesListView_SelectionChanged(object sender,
SelectionChangedEventArgs e)
{
    var listStyle = ((FrameworkElement)(e.AddedItems[0])).Tag.ToString();
```

```
    if (ListButton.IsChecked == true)
    {
        // Toggle button is on. Turn it off...
        if (listStyle == "none")
        {
            ListButton.IsChecked = false;
        }
        else
        {
            // or apply the new selection.
            ApplyListStyle(listStyle);
        }
    }
    else
    {
        // Toggle button is off. Turn it on, which will apply the selection
        // in the IsCheckedChanged event handler.
        ListButton.IsChecked = true;
    }
}

private void ApplyListStyle(string listStyle)
{
    Windows.UI.Text.ITextSelection selectedText = editor.Document.Selection;
    if (selectedText != null)
    {
        // Apply the list style to the selected text.
        var paragraphFormatting = selectedText.ParagraphFormat;
        if (listStyle == "none")
        {
            paragraphFormatting.ListType = Windows.UI.Text.MarkerType.None;
        }
        else if (listStyle == "bullet")
        {
            paragraphFormatting.ListType =
Windows.UI.Text.MarkerType.Bullet;
        }
        else if (listStyle == "numeric")
        {
            paragraphFormatting.ListType =
Windows.UI.Text.MarkerType.Arabic;
        }
        else if (listStyle == "alpha")
        {
            paragraphFormatting.ListType =
Windows.UI.Text.MarkerType.UppercaseEnglishLetter;
        }
        selectedText.ParagraphFormat = paragraphFormatting;
    }
}
```

UWP and WinUI 2

> **ⓘ Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

The DropDownButton, SplitButton, and ToggleSplitButton controls for UWP apps are included as part of WinUI 2. For more info, including installation instructions, see WinUI 2. APIs for these controls exist in both the Windows.UI.Xaml.Controls and Microsoft.UI.Xaml.Controls namespaces.

- ✓ **UWP APIs:** Button class, RepeatButton class, HyperlinkButton class, DropDownButton, SplitButton, ToggleSplitButton, ToggleButton, Click event, Command property, Content property
- ✓ **WinUI 2 Apis:** DropDownButton, SplitButton, ToggleSplitButton
- ✓ Open the WinUI 2 Gallery app and see the Button in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles and templates for all controls. WinUI 2.2 or later includes a new template for these controls that uses rounded corners. For more info, see Corner radius.

To use the code in this article with WinUI 2, use an alias in XAML (we use `muxc`) to represent the Windows UI Library APIs that are included in your project. See Get Started with WinUI 2 for more info.

XAML

```
xmlns:muxc="using:Microsoft.UI.Xaml.Controls"

<muxc:DropDownButton />
<muxc:SplitButton />
<muxc:ToggleSplitButton />
```

Check boxes

Article • 02/26/2025

A check box is used to select or deselect action items. It can be used for a single item or for a list of multiple items that a user can choose from. The control has three selection states: unselected, selected, and indeterminate. Use the indeterminate state when a collection of sub-choices have both unselected and selected states.

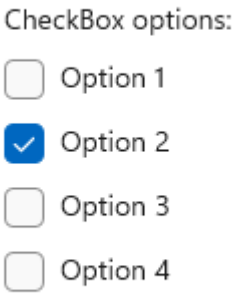
Is this the right control?

Use a **single check box** for a binary yes/no choice, such as with a "Remember me?" login scenario or with a terms of service agreement.

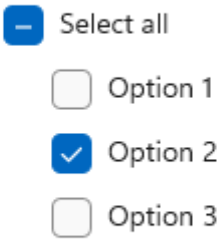
For a binary choice, the main difference between a **check box** and a toggle switch is that the check box is for status and the toggle switch is for action. You can delay committing a check box interaction (as part of a form submit, for example), while you should immediately commit a toggle switch interaction. Also, only check boxes allow for multi-selection.

Use **multiple check boxes** for multi-select scenarios in which a user chooses one or more items from a group of choices that are not mutually exclusive.

Create a group of check boxes when users can select any combination of options.



When options can be grouped, you can use an indeterminate check box to represent the whole group. Use the check box's indeterminate state when a user selects some, but not all, sub-items in the group.



Both **check box** and **radio button** controls let the user select from a list of options. Check boxes let the user select a combination of options. In contrast, radio buttons let the user make a single choice from mutually exclusive options. When there is more than one option but only one can be selected, use a radio button instead.

Recommendations

- Verify that the purpose and current state of the check box is clear.
- Limit check box text content to no more than two lines.
- Word the checkbox label as a statement that the check mark makes true and the absence of a check mark makes false.
- Use the default font unless your brand guidelines tell you to use another.
- If the text content is dynamic, consider how the control will resize and what will happen to visuals around it.

- If there are two or more mutually exclusive options from which to choose, consider using radio buttons.
- Don't put two check box groups next to each other. Use group labels to separate the groups.
- Don't use a check box as an on/off control or to perform a command; instead, use a toggle switch.
- Don't use a check box to display other controls, such as a dialog box.
- Use the indeterminate state to indicate that an option is set for some, but not all, sub-choices.
- When using indeterminate state, use subordinate check boxes to show which options are selected and which are not. Design the UI so that the user can get see the sub-choices.
- Don't use the indeterminate state to represent a third state. The indeterminate state is used to indicate that an option is set for some, but not all, sub-choices. So, don't allow users to set an indeterminate state directly. For an example of what not to do, this check box uses the indeterminate state to indicate medium spiciness:

Instead, use a radio button group that has three options.

Create a checkbox

✓ **Important APIs**: CheckBox class, Checked event, IsChecked property, Content property

Open the WinUI 3 Gallery app and see the CheckBox in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source

> code on GitHub

Create a simple check box

To assign a label to the checkbox, set the Content property. The label displays next to the checkbox.

This XAML creates a single check box that is used to agree to terms of service before a form can be submitted.

XAML

```
<CheckBox x:Name="termsOfServiceCheckBox"
          Content="I agree to the terms of service."/>
```

Here's the same check box created in code.

C#

```
CheckBox termsOfServiceCheckBox = new CheckBox();
termsOfServiceCheckBox.Content = "I agree to the terms of service.";
```

Bind to IsChecked

Use the IsChecked property to determine whether the check box is checked or cleared. You can bind the value of the IsChecked property to another binary value. However, because IsChecked is a nullable boolean value, you must either use a cast or a value converter to bind it to a boolean property. This depends on the actual binding type you are using and you will find examples below for each possible type.

In this example, the **IsChecked** property of the check box to agree to terms of service is bound to the IsEnabled property of a Submit button. The Submit button is enabled only if the terms of service are agreed to.

Using x:Bind

> **Note**
>
> We only show the relevant code here. For more info about data binding see Data binding overview. Specific {x:Bind} info (such as casting) is detailed in {x:Bind} markup extension.

XAML

```
<StackPanel Grid.Column="2" Margin="40">
    <CheckBox x:Name="termsOfServiceCheckBox" Content="I agree to the terms
of service."/>
    <Button Content="Submit"
            IsEnabled="{x:Bind (x:Boolean)termsOfServiceCheckBox.IsChecked,
Mode=OneWay}"/>
</StackPanel>
```

If the check box can also be in the **indeterminate** state, we use the binding's FallbackValue property to specify the boolean value representing this state. In this case, we don't want to have the Submit button enabled as well:

XAML

```
<Button Content="Submit"
        IsEnabled="{x:Bind (x:Boolean)termsOfServiceCheckBox.IsChecked,
Mode=OneWay, FallbackValue=False}"/>
```

Using x:Bind or Binding

> **Note**
>
> We only show the relevant code here using {x:Bind}. In the {Binding} example, we would replace {x:Bind} with {Binding}. For more info about data binding, value converters and differences between the {x:Bind} and {Binding} markup extensions, see Data binding overview.

XAML

```
...
<Page.Resources>
    <local:NullableBooleanToBooleanConverter
x:Key="NullableBooleanToBooleanConverter"/>
</Page.Resources>

...

<StackPanel Grid.Column="2" Margin="40">
    <CheckBox x:Name="termsOfServiceCheckBox" Content="I agree to the terms
of service."/>
    <Button Content="Submit"
            IsEnabled="{x:Bind termsOfServiceCheckBox.IsChecked,
                       Converter={StaticResource
```

```
NullableBooleanToBooleanConverter}, Mode=OneWay}"/>
</StackPanel>
```

C#

```
public class NullableBooleanToBooleanConverter : IValueConverter
{
    public object Convert(object value, Type targetType, object parameter,
string language)
    {
        if (value is bool?)
        {
            return (bool)value;
        }
        return false;
    }

    public object ConvertBack(object value, Type targetType, object
parameter, string language)
    {
        if (value is bool)
            return (bool)value;
        return false;
    }
}
```

Handle Click and Checked events

To perform an action when the check box state changes, you can handle either the Click event, or the Checked and Unchecked events.

The **Click** event occurs whenever the checked state changes. If you handle the Click event, use the **IsChecked** property to determine the state of the check box.

The **Checked** and **Unchecked** events occur independently. If you handle these events, you should handle both of them to respond to state changes in the check box.

In the following examples, we show handling the Click event, and the Checked and Unchecked events.

Multiple checkboxes can share the same event handler. This example creates four checkboxes for selecting pizza toppings. The four checkboxes share the same **Click** event handler to update the list of selected toppings.

XAML

```
<StackPanel Margin="40">
    <TextBlock Text="Pizza Toppings"/>
```

```
    <CheckBox Content="Pepperoni" x:Name="pepperoniCheckbox"
              Click="toppingsCheckbox_Click"/>
    <CheckBox Content="Beef" x:Name="beefCheckbox"
              Click="toppingsCheckbox_Click"/>
    <CheckBox Content="Mushrooms" x:Name="mushroomsCheckbox"
              Click="toppingsCheckbox_Click"/>
    <CheckBox Content="Onions" x:Name="onionsCheckbox"
              Click="toppingsCheckbox_Click"/>

    <!-- Display the selected toppings. -->
    <TextBlock Text="Toppings selected:"/>
    <TextBlock x:Name="toppingsList"/>
</StackPanel>
```

Here's the event handler for the Click event. Every time a checkbox is clicked, it examines the checkboxes to see which ones are checked and updates the list of selected toppings.

C#

```
private void toppingsCheckbox_Click(object sender, RoutedEventArgs e)
{
    string selectedToppingsText = string.Empty;
    CheckBox[] checkboxes = new CheckBox[] { pepperoniCheckbox,
beefCheckbox,
                                             mushroomsCheckbox,
onionsCheckbox };
    foreach (CheckBox c in checkboxes)
    {
        if (c.IsChecked == true)
        {
            if (selectedToppingsText.Length > 1)
            {
                selectedToppingsText += ", ";
            }
            selectedToppingsText += c.Content;
        }
    }
    toppingsList.Text = selectedToppingsText;
}
```

Use the indeterminate state

The CheckBox control inherits from ToggleButton and can have three states:

Expand table

State	Property	Value
checked	IsChecked	**true**

State	Property	Value
unchecked	IsChecked	**false**
indeterminate	IsChecked	**null**

For the check box to report the indeterminate state, you must set the IsThreeState property to **true**.

When options can be grouped, you can use an indeterminate check box to represent the whole group. Use the check box's indeterminate state when a user selects some, but not all, sub-items in the group.

In the following example, the "Select all" checkbox has its IsThreeState property set to **true**. The "Select all" checkbox is checked if all child elements are checked, unchecked if all child elements are unchecked, and indeterminate otherwise.

XAML

```
<StackPanel>
    <CheckBox x:Name="OptionsAllCheckBox" Content="Select all"
IsThreeState="True"
              Checked="SelectAll_Checked" Unchecked="SelectAll_Unchecked"
              Indeterminate="SelectAll_Indeterminate"/>
    <CheckBox x:Name="Option1CheckBox" Content="Option 1" Margin="24,0,0,0"
              Checked="Option_Checked" Unchecked="Option_Unchecked" />
    <CheckBox x:Name="Option2CheckBox" Content="Option 2" Margin="24,0,0,0"
              Checked="Option_Checked" Unchecked="Option_Unchecked"
IsChecked="True"/>
    <CheckBox x:Name="Option3CheckBox" Content="Option 3" Margin="24,0,0,0"
              Checked="Option_Checked" Unchecked="Option_Unchecked" />
</StackPanel>
```

C#

```
private void Option_Checked(object sender, RoutedEventArgs e)
{
    SetCheckedState();
}

private void Option_Unchecked(object sender, RoutedEventArgs e)
{
    SetCheckedState();
}

private void SelectAll_Checked(object sender, RoutedEventArgs e)
{
    Option1CheckBox.IsChecked = Option2CheckBox.IsChecked =
Option3CheckBox.IsChecked = true;
}
```

```
private void SelectAll_Unchecked(object sender, RoutedEventArgs e)
{
    Option1CheckBox.IsChecked = Option2CheckBox.IsChecked =
Option3CheckBox.IsChecked = false;
}

private void SelectAll_Indeterminate(object sender, RoutedEventArgs e)
{
    // If the SelectAll box is checked (all options are selected),
    // clicking the box will change it to its indeterminate state.
    // Instead, we want to uncheck all the boxes,
    // so we do this programmatically. The indeterminate state should
    // only be set programmatically, not by the user.

    if (Option1CheckBox.IsChecked == true &&
        Option2CheckBox.IsChecked == true &&
        Option3CheckBox.IsChecked == true)
    {
        // This will cause SelectAll_Unchecked to be executed, so
        // we don't need to uncheck the other boxes here.
        OptionsAllCheckBox.IsChecked = false;
    }
}

private void SetCheckedState()
{
    // Controls are null the first time this is called, so we just
    // need to perform a null check on any one of the controls.
    if (Option1CheckBox != null)
    {
        if (Option1CheckBox.IsChecked == true &&
            Option2CheckBox.IsChecked == true &&
            Option3CheckBox.IsChecked == true)
        {
            OptionsAllCheckBox.IsChecked = true;
        }
        else if (Option1CheckBox.IsChecked == false &&
            Option2CheckBox.IsChecked == false &&
            Option3CheckBox.IsChecked == false)
        {
            OptionsAllCheckBox.IsChecked = false;
        }
        else
        {
            // Set third state (indeterminate) by setting IsChecked to null.
            OptionsAllCheckBox.IsChecked = null;
        }
    }
}
```

UWP and WinUI 2

> **Important**
>
> The information and examples in this article are optimized for apps that use the **Windows App SDK** and **WinUI 3**, but are generally applicable to UWP apps that use **WinUI 2**. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

APIs for this control exist in the Windows.UI.Xaml.Controls namespace.

- ✓ **UWP APIs:** CheckBox class, Checked event, IsChecked property, Content property
- ✓ Open the WinUI 2 Gallery app and see the CheckBox in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles and templates for all controls. WinUI 2.2 or later includes a new template for this control that uses rounded corners. For more info, see Corner radius.

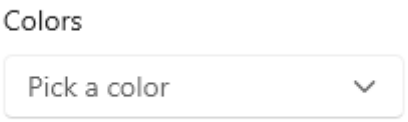
Combo box and list box

Article • 02/26/2025

Use a combo box (also known as a drop-down list) to present a list of items that a user can select from. A combo box starts in a compact state and expands to show a list of selectable items. A list box is similar to a combo box, but is not collapsible/does not have a compact state. You can learn more about list boxes at the end of this article.

When the combo box is closed, it either displays the current selection or is empty if there is no selected item. When the user expands the combo box, it displays the list of selectable items.

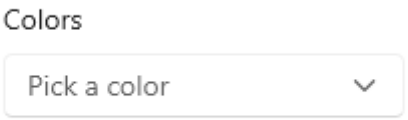


Is this the right control?

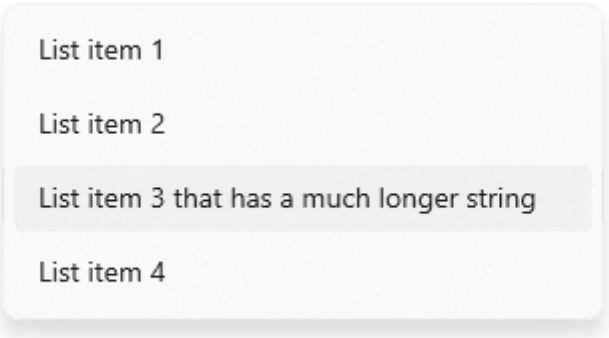
- Use a drop-down list to let users select a single value from a set of items that can be adequately represented with single lines of text.
- Use a list or grid view instead of a combo box to display items that contain multiple lines of text or images.
- When there are fewer than five items, consider using radio buttons (if only one item can be selected) or check boxes (if multiple items can be selected).
- Use a combo box when the selection items are of secondary importance in the flow of your app. If the default option is recommended for most users in most situations, showing all the items by using a list view might draw more attention to the options than necessary. You can save space and minimize distraction by using a combo box.

Examples

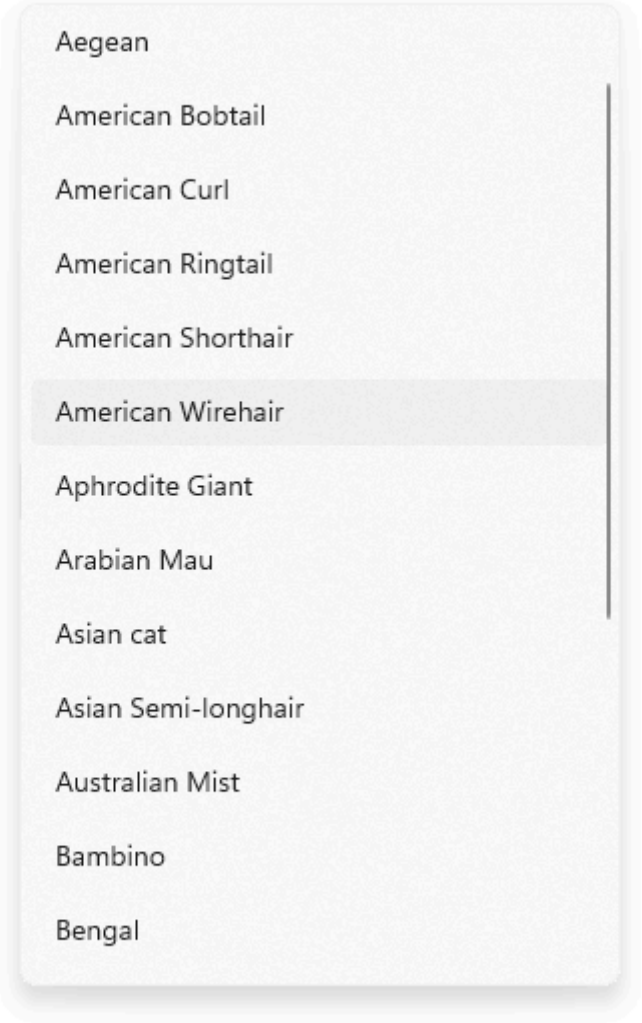
A combo box in its compact state can show a header.



Although combo boxes expand to support longer string lengths, avoid excessively long strings that are difficult to read.



If the collection in a combo box is long enough, a scroll bar will appear to accommodate it. Group items logically in the list.



Recommendations

- Limit the text content of combo box items to a single line.
- Sort items in a combo box in the most logical order. Group together related options and place the most common options at the top. Sort names in alphabetical order, numbers in numerical order, and dates in chronological order.

List boxes

A list box allows the user to choose either a single item or multiple items from a collection. List boxes are similar to drop-down lists, except that list boxes are always open—there is no compact (non-expanded) state for a list box. Items in the list can be scrolled if there isn't space to show everything.

Is a list box the right control?

- A list box can be useful when items in the list are important enough to prominently display, and when there's enough screen real estate, to show the full list.
- A list box should draw the user's attention to the full set of alternatives in an important choice. By contrast, a drop-down list initially draws the user's attention to the selected item.
- Avoid using a list box if:
  - There is a very small number of items for the list. A single-select list box that always has the same 2 options might be better presented as radio buttons. Also consider using radio buttons when there are 3 or 4 static items in the list.
  - The list box is single-select and it always has the same 2 options where one can be implied as not the other, such as "on" and "off." Use a single check box or a toggle switch.
  - There is a very large number of items. A better choice for long lists are grid view and list view. For very long lists of grouped data, semantic zoom is preferred.
  - The items are contiguous numerical values. If that's the case, consider using a slider.
  - The selection items are of secondary importance in the flow of your app or the default option is recommended for most users in most situations. Use a drop-down list instead.

Recommendations for list boxes

- The ideal range of items in a list box is 3 to 9.
- A list box works well when its items can dynamically vary.
- If possible, set the size of a list box so that its list of items don't need to be panned or scrolled.
- Verify that the purpose of the list box, and which items are currently selected, is clear.
- Reserve visual effects and animations for touch feedback, and for the selected state of items.
- Limit the list box item's text content to a single line. If the items are visuals, you can customize the size. If an item contains multiple lines of text or images, instead use a grid view or list view.
- Use the default font unless your brand guidelines indicate to use another.
- Don't use a list box to perform commands or to dynamically show or hide other controls.

Create a combo box

✓ **Important APIs**: ComboBox class, IsEditable property, Text property, TextSubmitted event, ListBox class

Open the WinUI 3 Gallery app and see the ComboBox in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

You populate the combo box by adding objects directly to the Items collection or by binding the ItemsSource property to a data source. Items added to the ComboBox are wrapped in ComboBoxItem containers.

Here's a simple combo box with items added in XAML.

XAML

```
<ComboBox Header="Colors" PlaceholderText="Pick a color" Width="200">
    <x:String>Blue</x:String>
    <x:String>Green</x:String>
    <x:String>Red</x:String>
    <x:String>Yellow</x:String>
</ComboBox>
```

The following example demonstrates binding a combo box to a collection of FontFamily objects.

XAML

```
<ComboBox x:Name="FontsCombo" Header="Fonts" Height="44" Width="296"
          ItemsSource="{x:Bind fonts}" DisplayMemberPath="Source"/>
```

C#

```
ObservableCollection<FontFamily> fonts = new
ObservableCollection<FontFamily>()
{
    fonts.Add(new FontFamily("Arial"));
    fonts.Add(new FontFamily("Courier New"));
    fonts.Add(new FontFamily("Times New Roman"));
};
```

Item selection

Like ListView and GridView, ComboBox is derived from Selector, so you can get the user's selection in the same standard way.

You can get or set the combo box's selected item by using the SelectedItem property, and get or set the index of the selected item by using the SelectedIndex property.

To get the value of a particular property on the selected data item, you can use the SelectedValue property. In this case, set the SelectedValuePath to specify which property on the selected item to get the value from.

> **Tip**
>
> If you set SelectedItem or SelectedIndex to indicate the default selection, an exception occurs if the property is set before the combo box Items collection is populated. Unless you define your Items in XAML, it's best to handle the combo box Loaded event, and set SelectedItem or SelectedIndex in the Loaded event handler.

You can bind to these properties in XAML, or handle the SelectionChanged event to respond to selection changes.

In the event handler code, you can get the selected item from the SelectionChangedEventArgs.AddedItems property. You can get the previously selected item (if any) from the SelectionChangedEventArgs.RemovedItems property. The AddedItems and RemovedItems collections each contain only 1 item because combo box does not support multiple selection.

This example shows how to handle the SelectionChanged event, and also how to bind to the selected item.

XAML

```
<StackPanel>
    <ComboBox x:Name="colorComboBox" Width="200"
              Header="Colors" PlaceholderText="Pick a color"
              SelectionChanged="ColorComboBox_SelectionChanged">
        <x:String>Blue</x:String>
        <x:String>Green</x:String>
        <x:String>Red</x:String>
        <x:String>Yellow</x:String>
    </ComboBox>

    <Rectangle x:Name="colorRectangle" Height="30" Width="100"
               Margin="0,8,0,0" HorizontalAlignment="Left"/>

    <TextBlock Text="{x:Bind colorComboBox.SelectedIndex, Mode=OneWay}"/>
```

```
    <TextBlock Text="{x:Bind colorComboBox.SelectedItem, Mode=OneWay}"/>
</StackPanel>
```

C#

```
private void ColorComboBox_SelectionChanged(object sender,
SelectionChangedEventArgs e)
{
    string colorName = e.AddedItems[0].ToString();
    Color color;
    switch (colorName)
    {
        case "Yellow":
            color = Colors.Yellow;
            break;
        case "Green":
            color = Colors.Green;
            break;
        case "Blue":
            color = Colors.Blue;
            break;
        case "Red":
            color = Colors.Red;
            break;
    }
    colorRectangle.Fill = new SolidColorBrush(color);
}
```

SelectionChanged and keyboard navigation

By default, the SelectionChanged event occurs when a user clicks, taps, or presses Enter on an item in the list to commit their selection, and the combo box closes. Selection doesn't change when the user navigates the open combo box list with the keyboard arrow keys.

To make a combo box that "live updates" while the user is navigating the open list with the arrow keys (like a Font selection drop-down), set SelectionChangedTrigger to Always. This causes the SelectionChanged event to occur when focus changes to another item in the open list.

Selected item behavior change

In Windows 10, version 1809 (SDK 17763) or later, the behavior of selected items is updated to support editable combo boxes.

Prior to SDK 17763, the value of the SelectedItem property (and therefore, SelectedValue and SelectedIndex) was required to be in the combo box's Items collection. Using the previous example, setting `colorComboBox.SelectedItem = "Pink"` results in:

- SelectedItem = null
- SelectedValue = null
- SelectedIndex = -1

In SDK 17763 and later, the value of the SelectedItem property (and therefore, SelectedValue and SelectedIndex) is not required to be in the combo box's Items collection. Using the previous example, setting `colorComboBox.SelectedItem = "Pink"` results in:

- SelectedItem = Pink
- SelectedValue = Pink
- SelectedIndex = -1

Text Search

Combo boxes automatically support search within their collections. As users type characters on a physical keyboard while focused on an open or closed combo box, candidates matching the user's string are brought into view. This functionality is especially helpful when navigating a long list. For example, when interacting with a drop-down containing a list of states, users can press the "w" key to bring "Washington" into view for quick selection. The text search is not case-sensitive.

You can set the IsTextSearchEnabled property to **false** to disable this functionality.

Make a combo box editable

By default, a combo box lets the user select from a pre-defined list of options. However, there are cases where the list contains only a subset of valid values, and the user should be able to enter other values that aren't listed. To support this, you can make the combo box editable.

To make a combo box editable, set the IsEditable property to **true**. Then, handle the TextSubmitted event to work with the value entered by the user.

By default, the SelectedItem value is updated when the user commits custom text. You can override this behavior by setting **Handled** to **true** in the TextSubmitted event args. When the event is marked as handled, the combo box will take no further action after the event and will stay in the editing state. SelectedItem will not be updated.

This example shows a simple editable combo box. The list contains simple strings, and any value entered by the user is used as entered.

A "recently used names" chooser lets the user enter custom strings. The 'RecentlyUsedNames' list contains some values that the user can choose from, but the user can also add a new, custom value. The 'CurrentName' property represents the currently entered name.

XAML

```
<ComboBox IsEditable="true"
          ItemsSource="{x:Bind RecentlyUsedNames}"
          SelectedItem="{x:Bind CurrentName, Mode=TwoWay}"/>
```

Text submitted

You can handle the TextSubmitted event to work with the value entered by the user. In the event handler, you will typically validate that the value entered by the user is valid, then use the value in your app. Depending on the situation, you might also add the value to the combo box's list of options for future use.

The TextSubmitted event occurs when these conditions are met:

- The IsEditable property is **true**
- The user enters text that does not match an existing entry in the combo box list
- The user presses Enter, or moves focus from the combo box.

The TextSubmitted event does not occur if the user enters text and then navigates up or down through the list.

Sample - Validate input and use locally

In this example, a font size chooser contains a set of values corresponding to the font size ramp, but the user may enter font sizes that are not in the list.

When the user adds a value that's not in the list, the font size updates, but the value is not added to the list of font sizes.

If the newly entered value is not valid, you use the SelectedValue to revert the Text property to the last known good value.

XAML

```
<ComboBox x:Name="fontSizeComboBox"
          IsEditable="true"
          ItemsSource="{x:Bind ListOfFontSizes}"
          TextSubmitted="FontSizeComboBox_TextSubmitted"/>
```

C#

```
private void FontSizeComboBox_TextSubmitted(ComboBox sender,
ComboBoxTextSubmittedEventArgs e)
{
    if (byte.TryParse(e.Text, out double newValue))
    {
        // Update the app's font size.
        _fontSize = newValue;
    }
    else
    {
        // If the item is invalid, reject it and revert the text.
        // Mark the event as handled so the framework doesn't update the
selected item.
        sender.Text = sender.SelectedValue.ToString();
        e.Handled = true;
    }
}
```

Sample - Validate input and add to list

Here, a "favorite color chooser" contains the most common favorite colors (Red, Blue, Green, Orange), but the user may enter a favorite color that's not in the list. When the user adds a valid color (like Pink), the newly entered color is added to the list and set as the active "favorite color".

XAML

```
<ComboBox x:Name="favoriteColorComboBox"
          IsEditable="true"
          ItemsSource="{x:Bind ListOfColors}"
          TextSubmitted="FavoriteColorComboBox_TextSubmitted"/>
```

C#

```
private void FavoriteColorComboBox_TextSubmitted(ComboBox sender,
ComboBoxTextSubmittedEventArgs e)
{
    if (IsValid(e.Text))
    {
        FavoriteColor newColor = new FavoriteColor()
```

```
        {
            ColorName = e.Text,
            Color = ColorFromStringConverter(e.Text)
        }
        ListOfColors.Add(newColor);
    }
    else
    {
        // If the item is invalid, reject it but do not revert the text.
        // Mark the event as handled so the framework doesn't update the
selected item.
        e.Handled = true;
    }
}

bool IsValid(string Text)
{
    // Validate that the string is: not empty; a color.
}
```

UWP and WinUI 2

> **ⓘ Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

APIs for this control exist in the Windows.UI.Xaml.Controls namespace.

- ✓ **UWP APIs:** ComboBox class, IsEditable property, Text property, TextSubmitted event, ListBox class
- ✓ Open the WinUI 2 Gallery app and see the ComboBox in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

> **ⓘ Note**
>
> The IsEditable property requires Windows 10, version 1809 (SDK 17763) or later.

WinUI 2.2 or later includes a new template for this control that uses rounded corners. For more info, see Corner radius.

Hyperlinks

Article • 02/26/2025

Hyperlinks navigate the user to another part of the app, to another app, or launch a specific uniform resource identifier (URI) using a separate browser app. There are two ways that you can add a hyperlink to a XAML app: the **Hyperlink** text element and **HyperlinkButton** control.

Is this the right control?

Use a hyperlink when you need text that responds when pressed and navigates the user to more information about the text that was pressed.

Choose the right type of hyperlink based on your needs:

- Use an inline **Hyperlink** text element inside of a text control. A Hyperlink element flows with other text elements and you can use it in any InlineCollection. Use a text hyperlink if you want automatic text wrapping and don't necessarily need a large hit target. Hyperlink text can be small and difficult to target, especially for touch.
- Use a **HyperlinkButton** for stand-alone hyperlinks. A HyperlinkButton is a specialized Button control that you can use anywhere that you would use a Button.
- Use a **HyperlinkButton** with an Image as its content to make a clickable image.

Recommendations

- Only use hyperlinks for navigation; don't use them for other actions.
- Use the Body style from the type ramp for text-based hyperlinks. Read about fonts and the Windows type ramp.
- Keep discrete hyperlinks far enough apart so that the user can differentiate between them and has an easy time selecting each one.
- Add tooltips to hyperlinks that indicate to where the user will be directed. If the user will be directed to an external site, include the top-level domain name inside the tooltip, and style the text with a secondary font color.

Create a Hyperlink text element

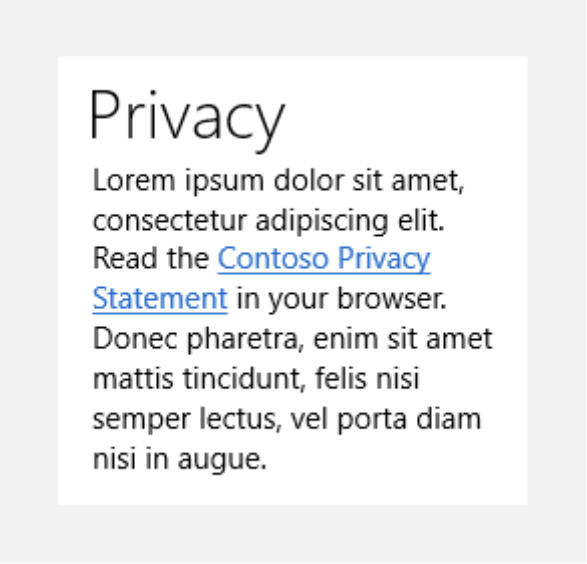
✔ **Important APIs**: Hyperlink text element

This example shows how to use a Hyperlink text element inside of a TextBlock.

XAML

```
<StackPanel Width="200">
    <TextBlock Text="Privacy" Style="{StaticResource
SubheaderTextBlockStyle}"/>
    <TextBlock TextWrapping="WrapWholeWords">
        <Span xml:space="preserve"><Run>Lorem ipsum dolor sit amet,
consectetur adipiscing elit. Read the </Run><Hyperlink
NavigateUri="http://www.contoso.com">Contoso Privacy Statement</Hyperlink>
<Run> in your browser.</Run> Donec pharetra, enim sit amet mattis tincidunt,
felis nisi semper lectus, vel porta diam nisi in augue.</Span>
    </TextBlock>
</StackPanel>
```

The hyperlink appears inline and flows with the surrounding text:



Tip

When you use a Hyperlink in a text control with other text elements in XAML, place the content in a **Span** container and apply the `xml:space="preserve"` attribute to the Span to keep the white space between the Hyperlink and other elements.

Create a HyperlinkButton

✔ **Important APIs**: HyperlinkButton control

Open the WinUI 3 Gallery app and see the Hyperlinks in action

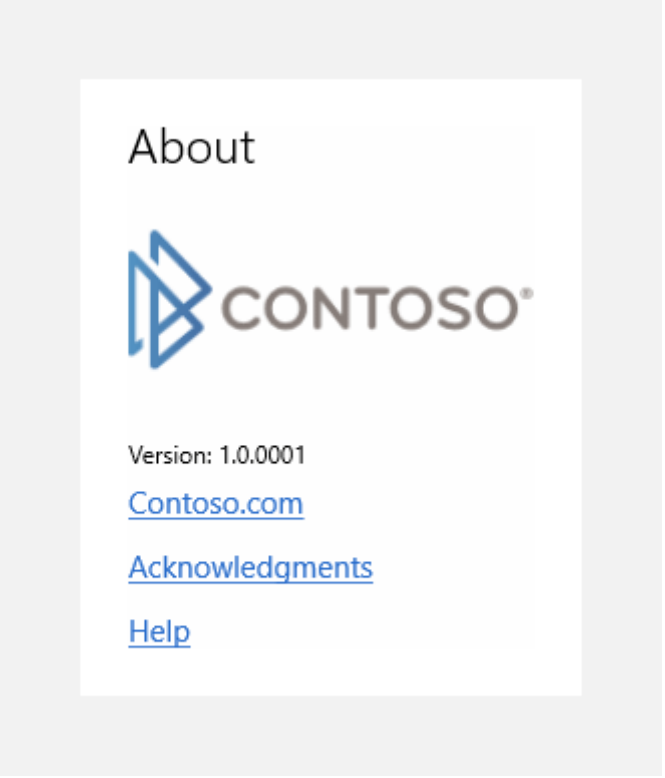
> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

Here's how to use a HyperlinkButton, both with text and with an image.

XAML

```
<StackPanel>
    <TextBlock Text="About" Style="{StaticResource TitleTextBlockStyle}"/>
    <HyperlinkButton NavigateUri="http://www.contoso.com">
        <Image Source="Assets/ContosoLogo.png"/>
    </HyperlinkButton>
    <TextBlock Text="Version: 1.0.0001" Style="{StaticResource
CaptionTextBlockStyle}"/>
    <HyperlinkButton Content="Contoso.com"
NavigateUri="http://www.contoso.com"/>
    <HyperlinkButton Content="Acknowledgments"
NavigateUri="http://www.contoso.com"/>
    <HyperlinkButton Content="Help" NavigateUri="http://www.contoso.com"/>
</StackPanel>
```

The hyperlink buttons with text content appear as marked-up text. The Contoso logo image is also a clickable hyperlink:



This example shows how to create a HyperlinkButton in code.

```
C#

HyperlinkButton helpLinkButton = new HyperlinkButton();
helpLinkButton.Content = "Help";
helpLinkButton.NavigateUri = new Uri("http://www.contoso.com");
```

Handle navigation

For both kinds of hyperlinks, you handle navigation the same way; you can set the **NavigateUri** property, or handle the **Click** event.

Navigate to a URI

To use the hyperlink to navigate to a URI, set the NavigateUri property. When a user clicks or taps the hyperlink, the specified URI opens in the default browser. The default browser runs in a separate process from your app.

> ⓘ **Note**
>
> A URI is represented by the Windows.Foundation.Uri class. When programming with .NET, this class is hidden and you should use the System.Uri class. For more info, see the reference pages for these classes.

You don't have to use **http:** or **https:** schemes. You can use schemes such as **ms-appx:**, **ms-appdata:**, or **ms-resources:**, if there's resource content at these locations that's appropriate to load in a browser. However, the **file:** scheme is specifically blocked. For more info, see URI schemes.

When a user clicks the hyperlink, the value of the NavigateUri property is passed to a system handler for URI types and schemes. The system then launches the app that is registered for the scheme of the URI provided for NavigateUri.

If you don't want the hyperlink to load content in a default Web browser (and don't want a browser to appear), then don't set a value for NavigateUri. Instead, handle the Click event, and write code that does what you want.

Handle the Click event

Use the Click event for actions other than launching a URI in a browser, such as navigation within the app. For example, if you want to load a new app page rather than opening a browser, call a Frame.Navigate method within your Click event handler to navigate to the new app page. If you want an external, absolute URI to load within a WebView control that also exists in your app, call WebView.Navigate as part of your Click handler logic.

You don't typically handle the Click event as well as specifying a NavigateUri value, as these represent two different ways of using the hyperlink element. If your intent is to open the URI in the default browser, and you have specified a value for NavigateUri, don't handle the Click event. Conversely, if you handle the Click event, don't specify a NavigateUri.

There's nothing you can do within the Click event handler to prevent the default browser from loading any valid target specified for NavigateUri; that action takes place automatically (asynchronously) when the hyperlink is activated and can't be canceled from within the Click event handler.

Hyperlink underlines

By default, hyperlinks are underlined. This underline is important because it helps meet accessibility requirements. Color-blind users use the underline to distinguish between hyperlinks and other text. If you disable underlines, you should consider adding some other type of formatting difference to distinguish hyperlinks from other text, such as FontWeight or FontStyle.

Hyperlink text elements

You can set the UnderlineStyle property to disable the underline. If you do, consider using FontWeight or FontStyle to differentiate your link text.

HyperlinkButton

By default, the HyperlinkButton appears as underlined text when you set a string as the value for the Content property.

The text does not appear underlined in the following cases:

- You set a TextBlock as the value for the Content property, and set the Text property on the TextBlock.
- You re-template the HyperlinkButton and change the name of the ContentPresenter template part.

If you need a button that appears as non-underlined text, consider using a standard Button control and applying the built-in `TextBlockButtonStyle` system resource to its Style property.

Notes for Hyperlink text element

This section applies only to the Hyperlink text element, not to the HyperlinkButton control.

Input events

Because a Hyperlink is not a UIElement, it does not have the set of UI element input events such as Tapped, PointerPressed, and so on. Instead, a Hyperlink has its own Click event, plus the implicit behavior of the system loading any URI specified as the NavigateUri. The system handles all input actions that should invoke the Hyperlink actions and raises the Click event in response.

Content

Hyperlink has restrictions on the content that can exist in its Inlines collection. Specifically, a Hyperlink only permits Run and other Span types that aren't another Hyperlink. InlineUIContainer can't be in the Inlines collection of a Hyperlink. Attempting to add restricted content throws an invalid argument exception or XAML parse exception.

Hyperlink and theme/style behavior

Hyperlink doesn't inherit from Control, so it doesn't have a Style property or a Template. You can edit the properties that are inherited from TextElement, such as Foreground or FontFamily, to change the appearance of a Hyperlink, but you can't use a common style or template to apply changes. Instead of using a template, consider using common resources for values of Hyperlink properties to provide consistency. Some properties of Hyperlink use defaults from a {ThemeResource} markup extension value provided by the system. This enables the Hyperlink appearance to switch in appropriate ways when the user changes the system theme at run-time.

The default color of the hyperlink is the accent color of the system. You can set the Foreground property to override this.

UWP and WinUI 2

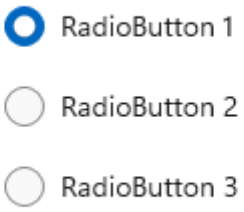
Radio buttons

Article • 02/26/2025

Radio buttons, also called option buttons, let users select one option from a collection of two or more mutually exclusive, but related, options. Radio buttons are always used in groups, and each option is represented by one radio button in the group.

In the default state, no radio button in a RadioButtons group is selected. That is, all radio buttons are cleared. However, once a user has selected a radio button, the user can't deselect the button to restore the group to its initial cleared state.

The singular behavior of a RadioButtons group distinguishes it from check boxes, which support multi-selection and deselection, or clearing.

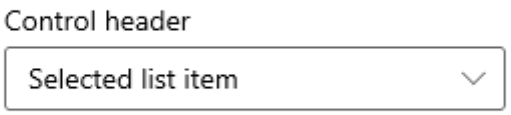


Is this the right control?

Use radio buttons to let users select from two or more mutually exclusive options.

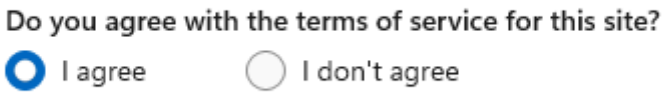
Use radio buttons when users need to see all options before they make a selection. Radio buttons emphasize all options equally, which means that some options might draw more attention than is necessary or desired.

Unless all options deserve equal attention, consider using other controls. For example, to recommend a single best option for most users and in most situations, use a combo box to display that best option as the default option.



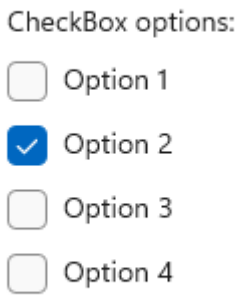
If there are only two possible options that can be expressed clearly as a single binary choice, such as on/off or yes/no, combine them into a single check box or toggle switch control. For example, use a single check box for "I agree" instead of two radio buttons for "I agree" and "I don't agree."

Don't use two radio buttons for a single binary choice:



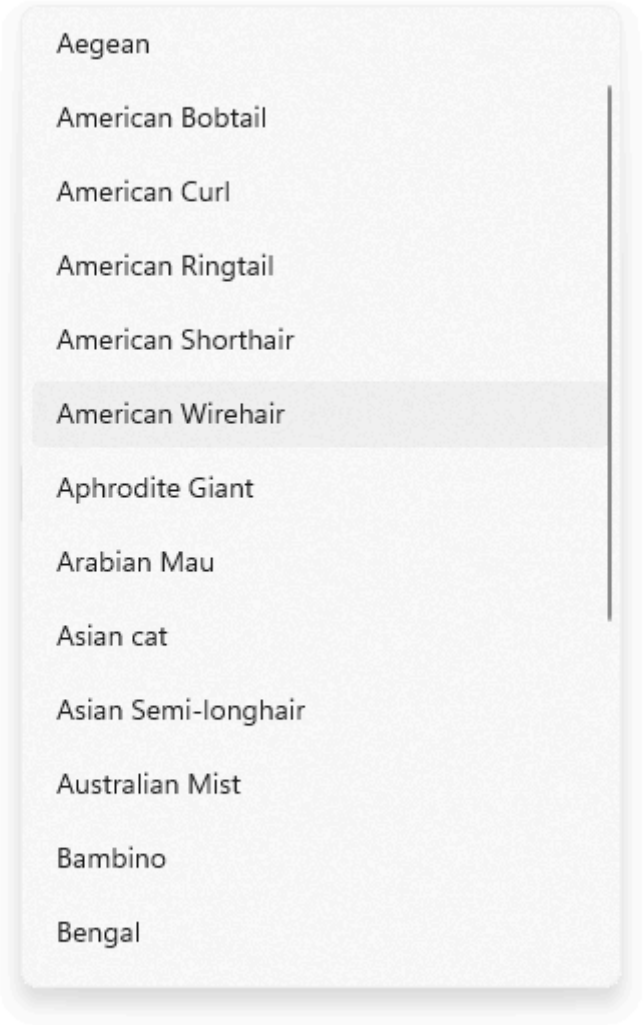
Use a check box instead:

When users can select multiple options, use check boxes.



When users' options lie within a range of values (for example, *10, 20, 30, ... 100*), use a slider control.

If there are more than eight options, use a combo box.



If the available options are based on an app's current context, or they can otherwise vary dynamically, use a list control.

Recommendations

- Make sure that the purpose and current state of a set of radio buttons is explicit.
- Limit the radio button's text label to a single line.
- If the text label is dynamic, consider how the button will automatically resize and what will happen to any visuals around it.

- Use the default font unless your brand guidelines tell you otherwise.
- Don't put two RadioButtons groups side by side. When two RadioButtons groups are right next to each other, it can be difficult for users to determine which buttons belong to which group.

RadioButtons overview

RadioButtons vs RadioButton

There are two ways to create radio button groups: RadioButtons and RadioButton.

- We recommend the **RadioButtons** control. This control simplifies layout, handles keyboard navigation and accessibility, and supports binding to a data source.
- You can use groups of individual **RadioButton** controls.

Keyboard access and navigation behavior have been optimized in the RadioButtons control. These improvements help both accessibility and keyboard power users move through the list of options more quickly and easily.

In addition to these improvements, the default visual layout of individual radio buttons in a RadioButtons group has been optimized through automated orientation, spacing, and margin settings. This optimization eliminates the requirement to specify these properties, as you might have to do when you use a more primitive grouping control, such as StackPanel or Grid.

Navigating a RadioButtons group

The `RadioButtons` control has special navigation behavior that helps keyboard users navigate the list more quickly and more easily.

Keyboard focus

The `RadioButtons` control supports two states:

- No radio button is selected
- One radio button is selected

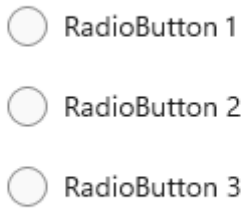
The next sections describe the focus behavior of the control in each state.

No radio button is selected

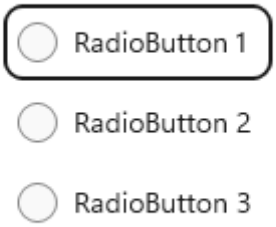
When no radio button is selected, the first radio button in the list gets focus.

> **Note**
>
> The item that receives tab focus from the initial tab navigation is not selected.

List without tab focus, no selection



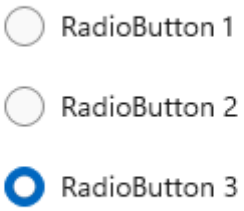
List with initial tab focus, no selection



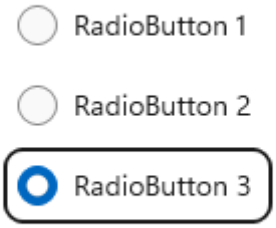
One radio button is selected

When a user tabs into the list where a radio button is already selected, the selected radio button gets focus.

List without tab focus



List with initial tab focus



Keyboard navigation

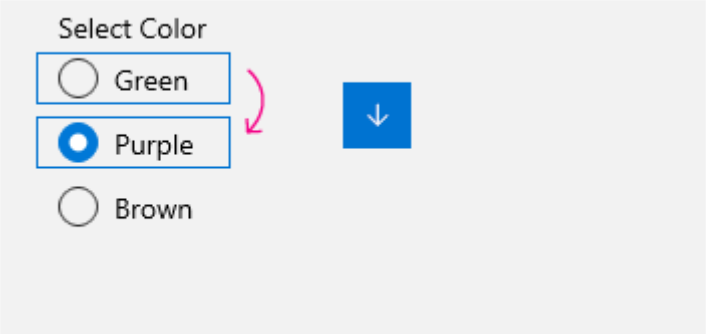
For more information about general keyboard navigation behaviors, see Keyboard interactions - Navigation.

When an item in a `RadioButtons` group already has focus, the user can use arrow keys for "inner navigation" between the items within the group. The Up and Down arrow keys move to the "next" or "previous" logical item, as defined in your XAML markup. The Left and Right arrow keys move spatially.

Navigation within single-column or single-row layouts

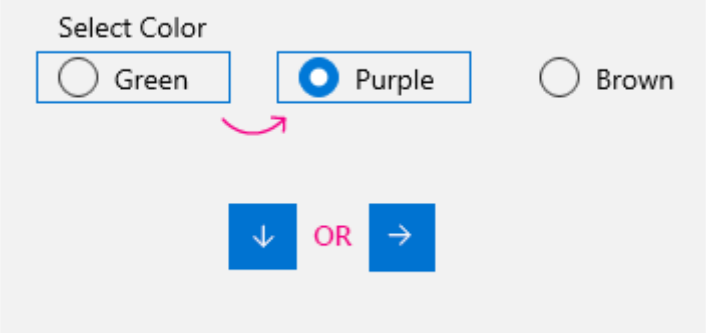
In a single-column or single-row layout, keyboard navigation results in the following behavior:

Single column



The Up arrow and Down arrow keys move between items.
The Left arrow and Right arrow keys do nothing.

Single row



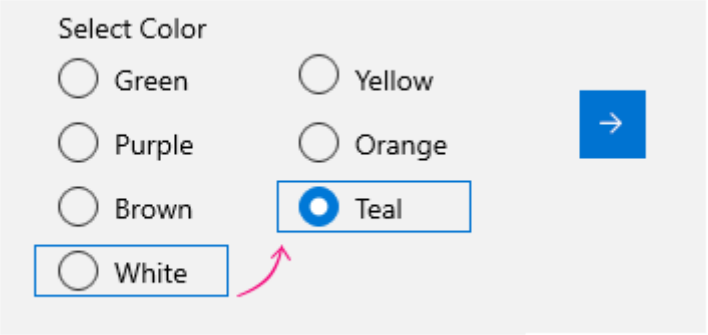
The Left and Up arrow keys move to the previous item, and the Right and Down arrow keys move to the next item.

Navigation within multi-column, multi-row layouts

In a multi-column, multi-row grid layout, keyboard navigation results in this behavior:

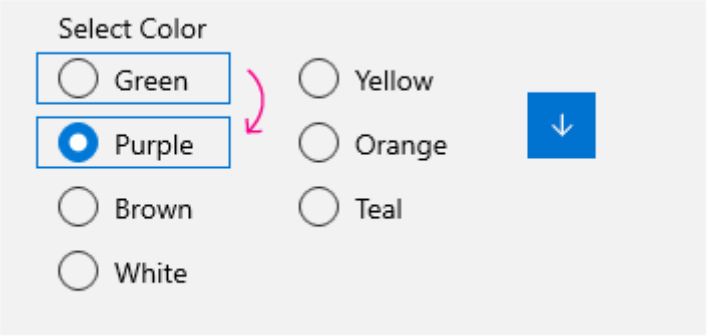
Left/Right arrow keys

The Left and Right arrow keys move focus horizontally between items in a row.



When focus is on the last item in a column and the Right or Left arrow key is pressed, focus moves to the last item in the next or previous column (if any).

Up/Down arrow keys



The Up and Down arrow keys move focus vertically between items in a column.

When focus is on the last item in a column and the Down arrow key is pressed, focus moves to the first item in the next column (if any). When focus is on the first item in a column and the Up arrow key is pressed, focus moves to the last item in the previous column (if any)

For more information, see Keyboard interactions.

Wrapping

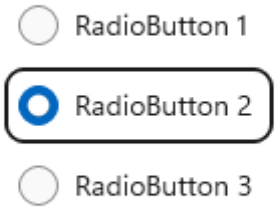
The RadioButtons group doesn't wrap focus from the first row or column to the last, or from the last row or column to the first. This is because, when users use a screen reader, a sense of boundary and a clear indication of beginning and end is lost, which makes it difficult for users with visual impairment to navigate the list.

The `RadioButtons` control also doesn't support enumeration, because the control is intended to contain a reasonable number of items (see Is this the right control?).

Selection follows focus

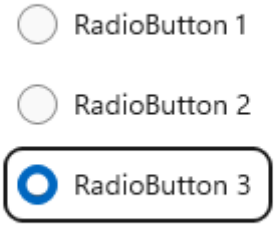
When you use the keyboard to navigate between items in a `RadioButtons` group, as focus moves from one item to the next, the newly focused item gets selected and the previously focused item is cleared.

Before keyboard navigation



Focus and selection before keyboard navigation.

After keyboard navigation



Focus and selection after keyboard navigation, where the Down arrow key moves focus to radio button 3, selects it, and clears radio button 2.

You can move focus without changing selection by using Ctrl+arrow keys to navigate. After focus is moved, you can use the Spacebar to select the item that currently has focus.

Navigating with game pad and remote control

If you use a game pad or remote control to move between radio buttons, the "selection follows focus" behavior is disabled, and the user must press the "A" button to select the radio button that currently has focus.

Accessibility behavior

The following table describes how Narrator handles a `RadioButtons` group and what is announced. This behavior depends on how a user has set the Narrator detail preferences.

Expand table

Action	Narrator announcement
Focus moves to a selected item	"*name*, RadioButton, selected, *x* of *N*"
Focus moves to an unselected item *(If navigating with Ctrl-arrow keys or Xbox gamepad, which indicates selection is not following focus.)*	"*name*, RadioButton, non-selected, *x* of *N*"

> **Note**
>
> The ***name*** that Narrator announces for each item is the value of the AutomationProperties.Name attached property if it is available for the item; otherwise, it is the value returned by the item's ToString method.
>
> ***x*** is the number of the current item. ***N*** is the total number of items in the group.

Create a WinUI RadioButtons group

✓ **Important APIs**: RadioButtons class, SelectedItem property, SelectedIndex property, SelectionChanged event, RadioButton class, IsChecked property, Checked event

Open the WinUI 3 Gallery app and see the RadioButton in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

The `RadioButtons` control uses a content model similar to an ItemsControl. This means that you can:

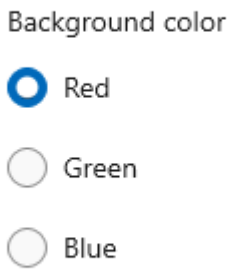
- Populate it by adding items directly to the Items collection or by binding data to its ItemsSource property.
- Use the SelectedIndex or SelectedItem properties to get and set which option is selected.
- Handle the SelectionChanged event to take action when an option is chosen.

Here, you declare a simple `RadioButtons` control with three options. The Header property is set to give the group a label, and the `SelectedIndex` property is set to provide a default option.

XAML

```
<RadioButtons Header="Background color"
              SelectedIndex="0"
              SelectionChanged="BackgroundColor_SelectionChanged">
    <x:String>Red</x:String>
    <x:String>Green</x:String>
    <x:String>Blue</x:String>
</RadioButtons>
```

The result looks like this:



To take an action when the user selects an option, handle the SelectionChanged event. Here, you change the background color of a Border element named "ExampleBorder" (`<Border x:Name="ExampleBorder" Width="100" Height="100"/>`).

C#

```
private void BackgroundColor_SelectionChanged(object sender,
SelectionChangedEventArgs e)
{
    if (ExampleBorder != null && sender is RadioButtons rb)
    {
        string colorName = rb.SelectedItem as string;
        switch (colorName)
        {
            case "Red":
                ExampleBorder.Background = new SolidColorBrush(Colors.Red);
                break;
            case "Green":
                ExampleBorder.Background = new
SolidColorBrush(Colors.Green);
                break;
            case "Blue":
                ExampleBorder.Background = new SolidColorBrush(Colors.Blue);
                break;
        }
    }
}
```

Tip

You can also get the selected item from the SelectionChangedEventArgs.AddedItems property. There will only be one selected item, at index 0, so you could get the selected item like this: `string colorName = e.AddedItems[0] as string;`.

Selection states

A radio button has two states: selected or cleared. When an option is selected in a `RadioButtons` group, you can get its value from the SelectedItem property, and its location in the collection from the SelectedIndex property. A radio button can be cleared if a user selects another radio button in the same group, but it can't be cleared if the user selects it again. However, you can clear a radio button group programmatically by setting it `SelectedItem = null`, or `SelectedIndex = -1`. (Setting `SelectedIndex` to any value outside the range of the `Items` collection results in no selection.)

RadioButtons content

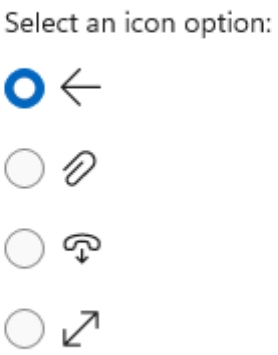
In the previous example, you populated the `RadioButtons` control with simple strings. The control provided the radio buttons, and used the strings as the label for each one.

However, you can populate the `RadioButtons` control with any object. Typically, you want the object to provide a string representation that can be used as a text label. In some cases, an image might be appropriate in place of text.

Here, SymbolIcon elements are used to populate the control.

XAML

```
<RadioButtons Header="Select an icon option:">
    <SymbolIcon Symbol="Back"/>
    <SymbolIcon Symbol="Attach"/>
    <SymbolIcon Symbol="HangUp"/>
    <SymbolIcon Symbol="FullScreen"/>
</RadioButtons>
```



You can also use individual RadioButton controls to populate the `RadioButtons` items. This is a special case that we discuss later. See RadioButton controls in a RadioButtons group.

A benefit of being able to use any object is that you can bind the `RadioButtons` control to a custom type in your data model. The next section demonstrates this.

Data binding

The `RadioButtons` control supports data binding to its ItemsSource property. This example shows how you can bind the control to a custom data source. The appearance and functionality of this example is the same as the previous background color example, but here, the color brushes are stored in the data model instead of being created in the `SelectionChanged` event handler.

XAML

```
<RadioButtons Header="Background color"
              SelectedIndex="0"
              SelectionChanged="BackgroundColor_SelectionChanged"
              ItemsSource="{x:Bind colorOptionItems}"/>
```

C#

```
public sealed partial class MainPage : Page
{
    // Custom data item.
    public class ColorOptionDataModel
    {
        public string Label { get; set; }
        public SolidColorBrush ColorBrush { get; set; }

        public override string ToString()
        {
            return Label;
        }
    }

    List<ColorOptionDataModel> colorOptionItems;

    public MainPage1()
    {
        this.InitializeComponent();

        colorOptionItems = new List<ColorOptionDataModel>();
        colorOptionItems.Add(new ColorOptionDataModel()
            { Label = "Red", ColorBrush = new SolidColorBrush(Colors.Red)
});
        colorOptionItems.Add(new ColorOptionDataModel()
            { Label = "Green", ColorBrush = new
SolidColorBrush(Colors.Green) });
        colorOptionItems.Add(new ColorOptionDataModel()
            { Label = "Blue", ColorBrush = new SolidColorBrush(Colors.Blue)
});
    }

    private void BackgroundColor_SelectionChanged(object sender,
SelectionChangedEventArgs e)
    {
        var option = e.AddedItems[0] as ColorOptionDataModel;
        ExampleBorder.Background = option?.ColorBrush;
    }
}
```

RadioButton controls in a RadioButtons group

You can use individual RadioButton controls to populate the `RadioButtons` items. You might do this to get access to certain properties, like `AutomationProperties.Name`; or you might have existing `RadioButton` code, but want to take advantage of the layout and navigation of `RadioButtons`.

XAML

```
<RadioButtons Header="Background color">
    <RadioButton Content="Red" Tag="red" AutomationProperties.Name="red"/>
    <RadioButton Content="Green" Tag="green"
AutomationProperties.Name="green"/>
    <RadioButton Content="Blue" Tag="blue"
AutomationProperties.Name="blue"/>
</RadioButtons>
```

When you use `RadioButton` controls in a `RadioButtons` group, the `RadioButtons` control knows how to present the `RadioButton`, so you won't end up with two selection circles.

However, there are some behaviors you should be aware of. We recommend that you handle state and events on the individual controls or on `RadioButtons`, but not both, to avoid conflicts.

This table shows the related events and properties on both controls.

Expand table

RadioButton	RadioButtons
Checked, Unchecked, Click	SelectionChanged
IsChecked	SelectedItem, SelectedIndex

If you handle events on an individual `RadioButton`, such as `Checked` or `Unchecked`, and also handle the `RadioButtons.SelectionChanged` event, both events will fire. The `RadioButton` event occurs first, and then the `RadioButtons.SelectionChanged` event occurs, which could result in conflicts.

The `IsChecked`, `SelectedItem`, and `SelectedIndex` properties stay synchronized. A change to one property updates the other two.

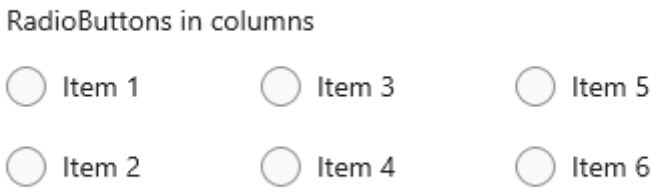
The RadioButton.GroupName property is ignored. The group is created by the `RadioButtons` control.

Defining multiple columns

By default, the `RadioButtons` control arranges its radio buttons vertically in a single column. You can set the MaxColumns property to make the control arrange the radio buttons in multiple columns. (When you do this, they are laid out in column-major order, where items fill in from top to bottom, then left to right.)

XAML

```
<RadioButtons Header="RadioButtons in columns" MaxColumns="3">
    <x:String>Item 1</x:String>
    <x:String>Item 2</x:String>
    <x:String>Item 3</x:String>
    <x:String>Item 4</x:String>
    <x:String>Item 5</x:String>
    <x:String>Item 6</x:String>
</RadioButtons>
```



> **Tip**
>
> To have items arranged in a single horizontal row, set `MaxColumns` equal to the number of items in the group.

Create your own RadioButton group

> **Important**
>
> We recommend using the `RadioButtons` control to group `RadioButton` elements.

Radio buttons work in groups. You can group individual RadioButton controls in either of two ways:

- Put them inside the same parent container.
- Set the GroupName property on each radio button to the same value.

In this example, the first group of radio buttons is implicitly grouped by being in the same stack panel. The second group is divided between two stack panels, so `GroupName` is used to explicitly group them into a single group.

XAML

```
<StackPanel>
    <StackPanel>
        <TextBlock Text="Background" Style="{ThemeResource
BaseTextBlockStyle}"/>
        <!-- Group 1 - implicit grouping -->
        <StackPanel Orientation="Horizontal">
            <RadioButton Content="Green" Tag="green"
Checked="BGRadioButton_Checked"/>
            <RadioButton Content="Yellow" Tag="yellow"
Checked="BGRadioButton_Checked"/>
            <RadioButton Content="White" Tag="white"
Checked="BGRadioButton_Checked"
                         IsChecked="True"/>
        </StackPanel>
    </StackPanel>

    <StackPanel>
        <TextBlock Text="BorderBrush" Style="{ThemeResource
BaseTextBlockStyle}"/>
        <!-- Group 2 - grouped by GroupName -->
        <StackPanel Orientation="Horizontal">
            <StackPanel>
                <RadioButton Content="Green" Tag="green"
GroupName="BorderBrush"
                             Checked="BorderRadioButton_Checked"/>
                <RadioButton Content="Yellow" Tag="yellow"
GroupName="BorderBrush"
                             Checked="BorderRadioButton_Checked"
IsChecked="True"/>
                <RadioButton Content="White" Tag="white"
GroupName="BorderBrush"
                             Checked="BorderRadioButton_Checked"/>
            </StackPanel>
        </StackPanel>
    </StackPanel>
    <Border x:Name="ExampleBorder"
            BorderBrush="#FFFFD700" Background="#FFFFFFFF"
            BorderThickness="10" Height="50" Margin="0,10"/>
</StackPanel>
```

C#

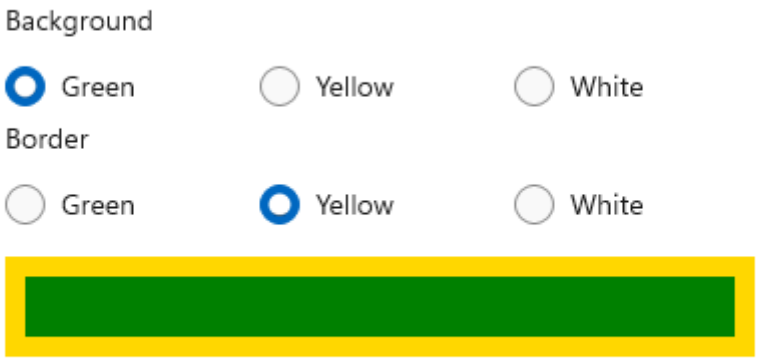
```
private void BGRadioButton_Checked(object sender, RoutedEventArgs e)
{
    RadioButton rb = sender as RadioButton;
```

```
    if (rb != null && ExampleBorder != null)
    {
        string colorName = rb.Tag.ToString();
        switch (colorName)
        {
            case "yellow":
                ExampleBorder.Background = new
SolidColorBrush(Colors.Yellow);
                break;
            case "green":
                ExampleBorder.Background = new
SolidColorBrush(Colors.Green);
                break;
            case "white":
                ExampleBorder.Background = new
SolidColorBrush(Colors.White);
                break;
        }
    }
}

private void BorderRadioButton_Checked(object sender, RoutedEventArgs e)
{
    RadioButton rb = sender as RadioButton;

    if (rb != null && ExampleBorder != null)
    {
        string colorName = rb.Tag.ToString();
        switch (colorName)
        {
            case "yellow":
                ExampleBorder.BorderBrush = new
SolidColorBrush(Colors.Gold);
                break;
            case "green":
                ExampleBorder.BorderBrush = new
SolidColorBrush(Colors.DarkGreen);
                break;
            case "white":
                ExampleBorder.BorderBrush = new
SolidColorBrush(Colors.White);
                break;
        }
    }
}
```

These two groups of `RadioButton` controls look like this:



Radio button states

A radio button has two states: selected or cleared. When a radio button is selected, its IsChecked property is `true`. When a radio button is cleared, its `IsChecked` property is `false`. A radio button can be cleared if a user selects another radio button in the same group, but it can't be cleared if the user selects it again. However, you can clear a radio button programmatically by setting its `IsChecked` property to `false`.

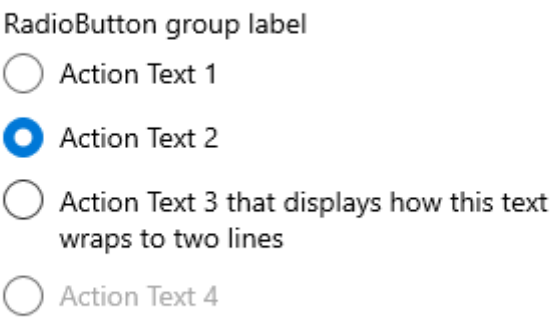
Visuals to consider

The default spacing of individual `RadioButton` controls is different than the spacing provided by a `RadioButtons` group. To apply the `RadioButtons` spacing to individual `RadioButton` controls, use a `Margin` value of `0,0,7,3`, as shown here.

XAML

```
<StackPanel>
    <StackPanel.Resources>
        <Style TargetType="RadioButton">
            <Setter Property="Margin" Value="0,0,7,3"/>
        </Style>
    </StackPanel.Resources>
    <TextBlock Text="Background"/>
    <RadioButton Content="Item 1"/>
    <RadioButton Content="Item 2"/>
    <RadioButton Content="Item 3"/>
</StackPanel>
```

The following images show the preferred spacing of radio buttons in a group.



> **Note**
>
> If you're using a WinUI RadioButtons control, the spacing, margins, and orientation are already optimized.

UWP and WinUI 2

> **Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.

This section contains information you need to use the control in a UWP or WinUI 2 app.

The RadioButtons control for UWP apps is included as part of WinUI 2. For more info, including installation instructions, see WinUI 2. APIs for these controls exist in both the Windows.UI.Xaml.Controls and Microsoft.UI.Xaml.Controls namespaces.

- ✓ **UWP APIs**: RadioButton class, IsChecked property, Checked event
- ✓ **WinUI 2 Apis**: RadioButtons class, SelectedItem property, SelectedIndex property, SelectionChanged event
- ✓ Open the WinUI 2 Gallery app and see the RadioButton in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

There are two ways to create radio button groups.

- Starting with WinUI 2.3, we recommend the **RadioButtons** control. This control simplifies layout, handles keyboard navigation and accessibility, and supports binding to a data source.
- You can use groups of individual **RadioButton** controls. If your app does not use WinUI 2.3 or later, this is the only option.

We recommend using the latest WinUI 2 to get the most current styles and templates for all controls.

To use the code in this article with WinUI 2, use an alias in XAML (we use `muxc`) to represent the Windows UI Library APIs that are included in your project. See Get Started with WinUI 2 for more info.

XAML

```
xmlns:muxc="using:Microsoft.UI.Xaml.Controls"

<muxc:RadioButtons />
```

Rating control

Article • 02/26/2025

The rating control allows users to view and set ratings that reflect degrees of satisfaction with content and services. Users can interact with the rating control with touch, pen, mouse, gamepad, or keyboard. The follow guidance shows how to use the rating control's features to provide flexibility and customization.

Overview

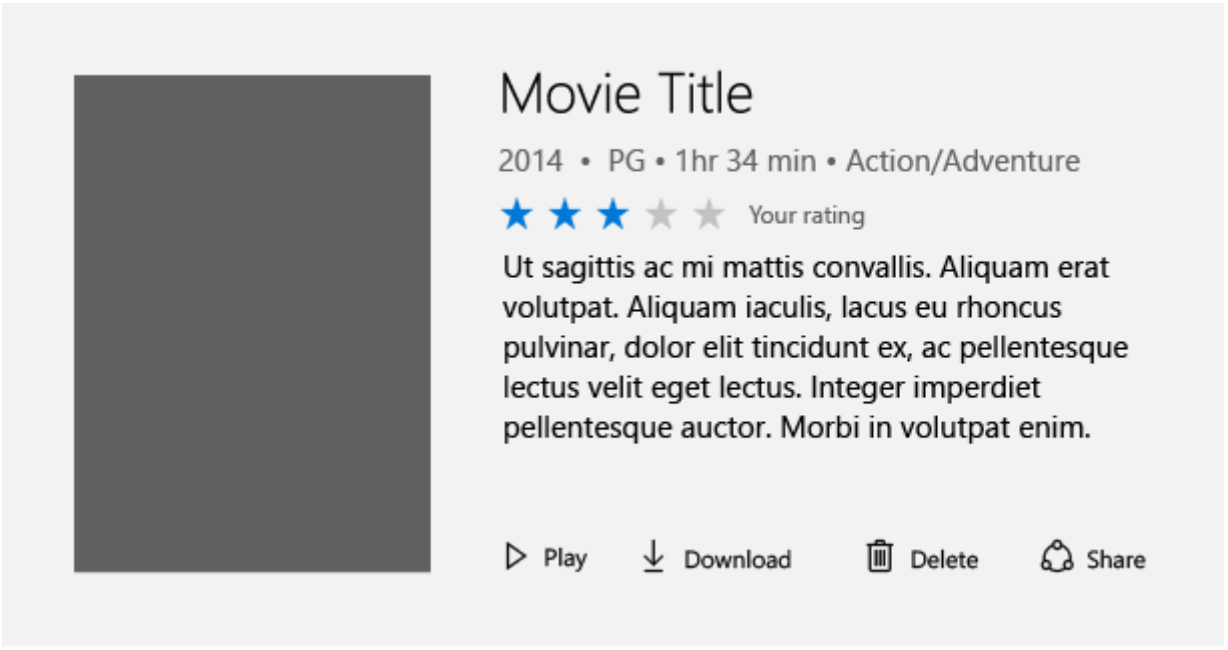
The rating control can be used to enter a rating, or made read-only to display a rating.

Editable rating with placeholder value

Perhaps the most common way to use the rating control is to display an average rating while still allowing the user to enter their own rating value. In this scenario, the rating control is initially set to reflect the average satisfaction rating of all users of a particular service or type of content (such as a music, videos, books, etc.). It remains in this state until a user interacts with the control with the goal of individually rating an item. This interaction changes the state of the ratings control to reflect the user's personal satisfaction rating.

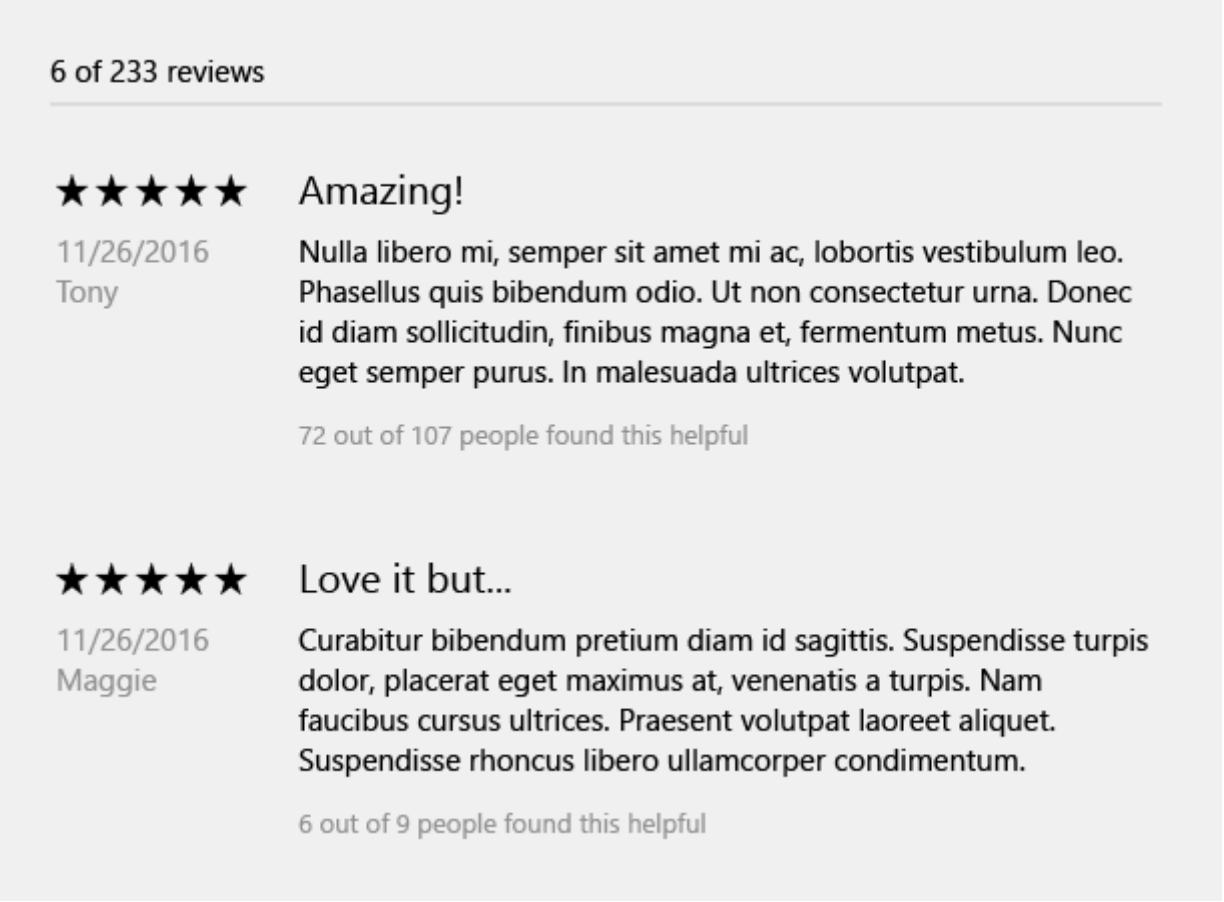
Initial average rating state

Representation of user rating once set



Read-only rating mode

Sometimes you need to show ratings of secondary content, such as that displayed in recommended content or when displaying a list of comments and their corresponding ratings. In this case, the user shouldn't be able to edit the rating, so you can make the control read-only. The read only mode is also the recommended way of using the rating control when it is used in very large virtualized lists of content, for both UI design and performance reasons.



Create a rating control

✓ **Important APIs**: RatingControl class

Open the WinUI 3 Gallery app and see RatingControl in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

Editable rating control

This code shows how to create an editable rating control with a placeholder value.

XAML

```
<RatingControl x:Name="MyRating" ValueChanged="RatingChanged"/>
```

C#

```
private void RatingChanged(RatingControl sender, object args)
{
    if (sender.Value == null)
```

```
    {
        MyRating.Caption = "(" + SomeWebService.HowManyPreviousRatings() +
")";
    }
    else
    {
        MyRating.Caption = "Your rating";
    }
}
```

Read-only rating control

This code shows how to create a read-only rating control.

XAML

```
<RatingControl IsReadOnly="True"/>
```

Additional functionality

The rating control has many additional features which can be used. Details for using these features can be found in our reference documentation. Here is a non-comprehensive list of additional functionality:

- Great long list performance
- Compact sizing for tight UI scenarios
- Continuous value fill and rating
- Spacing customization
- Disable growth animations
- Customization of the number of stars

UWP and WinUI 2

> **ⓘ Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.

This section contains information you need to use the control in a UWP or WinUI 2 app.

The RatingControl for UWP apps is included as part of WinUI 2. For more info, including installation instructions, see WinUI 2. APIs for this control exist in both the Windows.UI.Xaml.Controls and Microsoft.UI.Xaml.Controls namespaces.

```
xmlns:muxc="using:Microsoft.UI.Xaml.Controls"

<muxc:RatingControl />
```

Sliders

Article • 02/26/2025

A slider is a control that lets the user select from a range of values by moving a thumb control along a track.

Is this the right control?

Use a slider when you want your users to be able to set defined, contiguous values (such as volume or brightness) or a range of discrete values (such as screen resolution settings).

A slider is a good choice when you know that users think of the value as a relative quantity, not a numeric value. For example, users think about setting their audio volume to low or medium—not about setting the value to 2 or 5.

Don't use a slider for binary settings. Use a toggle switch instead.

Here are some additional factors to consider when deciding whether to use a slider:

- **Does the setting seem like a relative quantity?** If not, use radio buttons or a list box.
- **Is the setting an exact, known numeric value?** If so, use a numeric text box.
- **Would a user benefit from instant feedback on the effect of setting changes?** If so, use a slider. For example, users can choose a color more easily by immediately seeing the effect of changes to hue, saturation, or luminosity values.
- **Does the setting have a range of four or more values?** If not, use radio buttons.
- **Can the user change the value?** Sliders are for user interaction. If a user can't ever change the value, use read-only text instead.

If you are deciding between a slider and a numeric text box, use a numeric text box if:

- Screen space is tight.
- The user is likely to prefer using the keyboard.

Use a slider if:

- Users will benefit from instant feedback.

Recommendations

- Size the control so that users can easily set the value they want. For settings with discrete values, make sure the user can easily select any value using the mouse. Make sure the endpoints of the slider always fit within the bounds of a view.
- Give immediate feedback while or after a user makes a selection (when practical). For example, the Windows volume control beeps to indicate the selected audio volume.
- Use labels to show the range of values. Exception: If the slider is vertically oriented and the top label is Maximum, High, More, or equivalent, you can omit the other labels because the meaning is clear.
- Disable all associated labels or feedback visuals when you disable the slider.
- Consider the direction of text when setting the flow direction and/or orientation of your slider. Script flows from left to right in some languages, and from right to left in others.
- Don't use a slider as a progress indicator.
- Don't change the size of the slider thumb from the default size.
- Don't create a continuous slider if the range of values is large and users will most likely select one of several representative values from the range. Instead, use those values as the only steps allowed. For example if time value might be up to 1 month but users only need to pick from 1 minute, 1 hour, 1 day or 1 month, then create a slider with only 4 step points.

Additional usage guidance

Choosing the right layout: horizontal or vertical

You can orient your slider horizontally or vertically. Use these guidelines to determine which layout to use.

- Use a natural orientation. For example, if the slider represents a real-world value that is normally shown vertically (such as temperature), use a vertical orientation.
- If the control is used to seek within media, like in a video app, use a horizontal orientation.
- When using a slider in page that can be panned in one direction (horizontally or vertically), use a different orientation for the slider than the panning direction. Otherwise, users might swipe the slider and change its value accidentally when they try to pan the page.

- If you're still not sure which orientation to use, use the one that best fits your page layout.

Range direction

The range direction is the direction you move the slider when you slide it from its current value to its max value.

- For vertical slider, put the largest value at the top of the slider, regardless of reading direction. For example, for a volume slider, always put the maximum volume setting at the top of the slider. For other types of values (such as days of the week), follow the reading direction of the page.
- For horizontal styles, put the lower value on the left side of the slider for left-to-right page layout, and on the right for right-to-left page layout.
- The one exception to the previous guideline is for media seek bars: always put the lower value on the left side of the slider.

Steps and tick marks

- Use step points if you don't want the slider to allow arbitrary values between min and max. For example, if you use a slider to specify the number of movie tickets to buy, don't allow floating point values. Give it a step value of 1.
- If you specify steps (also known as snap points), make sure that the final step aligns to the slider's max value.
- Use tick marks when you want to show users the location of major or significant values. For example, a slider that controls a zoom might have tick marks for 50%, 100%, and 200%.
- Show tick marks when users need to know the approximate value of the setting.
- Show tick marks and a value label when users need to know the exact value of the setting they choose, without interacting with the control. Otherwise, they can use the value tooltip to see the exact value.
- Always show tick marks when step points aren't obvious. For example, if the slider is 200 pixels wide and has 200 snap points, you can hide the tick marks because users won't notice the snapping behavior. But if there are only 10 snap points, show tick marks.

Labels

- **Slider labels**

  The slider label indicates what the slider is used for.

    - Use a label with no ending punctuation (this is the convention for all control labels).
    - Position labels above the slider when the slider is in a form that places most of its labels above their controls.
    - Position labels to the sides when the slider is in a form that places most of its labels to the side of their controls.
    - Avoid placing labels below the slider because the user's finger might occlude the label when the user touches the slider.

- **Range labels**

  The range, or fill, labels describe the slider's minimum and maximum values.
    - Label the two ends of the slider range, unless a vertical orientation makes this unnecessary.
    - Use only one word, if possible, for each label.
    - Don't use ending punctuation.
    - Make sure these labels are descriptive and parallel. Examples: Maximum/Minimum, More/Less, Low/High, Soft/Loud.

- **Value labels**

  A value label displays the current value of the slider.
    - If you need a value label, display it below the slider.
    - Center the text relative to the control and include the units (such as pixels).
    - Since the slider's thumb is covered during scrubbing, consider showing the current value some other way, with a label or other visual. A slider setting text size could render some sample text of the right size beside the slider.

Appearance and interaction

A slider is composed of a track and a thumb. The track is a bar (which can optionally show various styles of tick marks) representing the range of values that can be input. The thumb is a selector, which the user can position by either tapping the track or by scrubbing back and forth on it.

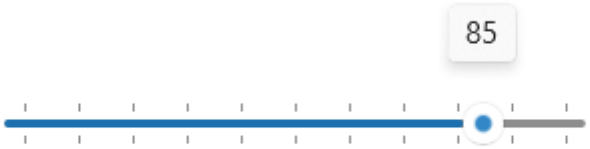
A slider has a large touch target. To maintain touch accessibility, a slider should be positioned far enough away from the edge of the display.

When you're designing a custom slider, consider ways to present all the necessary info to the user with as little clutter as possible. Use a value label if a user needs to know the units in order to understand the setting; find creative ways to represent these values graphically. A slider that controls volume, for example, could display a speaker graphic

without sound waves at the minimum end of the slider, and a speaker graphic with sound waves at the maximum end.

Examples

A slider with tick marks at 10 point intervals from 0 to 100.



Create a slider

✓ **Important APIs**: Slider class, Value property, ValueChanged event

Open the WinUI 3 Gallery app and see the Slider in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

Here's how to create a slider in XAML.

XAML

```
<Slider x:Name="volumeSlider" Header="Volume" Width="200"
        ValueChanged="Slider_ValueChanged"/>
```

Here's how to create a slider in code.

C#

```
Slider volumeSlider = new Slider();
volumeSlider.Header = "Volume";
volumeSlider.Width = 200;
volumeSlider.ValueChanged += Slider_ValueChanged;

// Add the slider to a parent container in the visual tree.
stackPanel1.Children.Add(volumeSlider);
```

You get and set the value of the slider from the Value property. To respond to value changes, you can use data binding to bind to the Value property, or handle the ValueChanged event.

C#

```
private void Slider_ValueChanged(object sender,
RangeBaseValueChangedEventArgs e)
{
    Slider slider = sender as Slider;
    if (slider != null)
    {
        media.Volume = slider.Value;
    }
}
```

UWP and WinUI 2

> **Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

APIs for this control exist in the Windows.UI.Xaml.Controls namespace.

- ✓ **UWP APIs:** Slider class, Value property, ValueChanged event
- ✓ Open the WinUI 2 Gallery app and see the Slider in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles and templates for all controls. WinUI 2.2 or later includes a new template for this control that uses rounded corners. For more info, see Corner radius.

- Slider class

Toggle switches

Article • 02/26/2025

The toggle switch represents a physical switch that allows users to turn things on or off, like a light switch. Use toggle switch controls to present users with two mutually exclusive options (such as on/off), where choosing an option provides immediate results.

To create a toggle switch control, you use the ToggleSwitch class.

Is this the right control?

Use a toggle switch for binary operations that take effect right after the user flips the toggle switch.

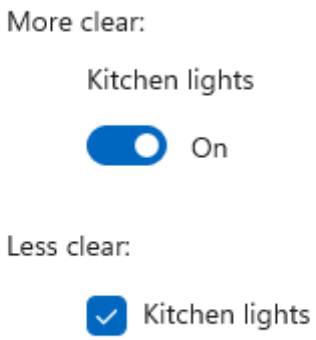
Think of the toggle switch as a physical power switch for a device: you flip it on or off when you want to enable or disable the action performed by the device.

To make the toggle switch easy to understand, label it with one or two words, preferably nouns, that describe the functionality it controls. For example, "WiFi" or "Kitchen lights."

Choosing between toggle switch and check box

For some actions, either a toggle switch or a check box might work. To decide which control would work better, follow these tips:

- Use a toggle switch for binary settings when changes become effective immediately after the user changes them.



In this example, it's clear with the toggle switch that the kitchen lights are set to "On." But with the checkbox, the user needs to think about whether the lights are on now or whether they need to check the box to turn the lights on.

- Use check boxes for optional ("nice to have") items.
- Use a checkbox when the user has to perform extra steps for changes to be effective. For example, if the user must click a "submit" or "next" button to apply changes, use a check box.
- Use check boxes when the user can select multiple items that are related to a single setting or feature.

Recommendations

- Use the default On and Off labels when you can; only replace them when it's necessary for the toggle switch to make sense. If you replace them, use a single word that more accurately describes the toggle. In general, if the words "On" and "Off" don't describe the action tied to a toggle switch, you might need a different control.
- Avoid replacing the On and Off labels unless you must; stick with the default labels unless the situation calls for custom ones.

Create a toggle switch

✓ **Important APIs**: ToggleSwitch class, IsOn property, Toggled event

Open the WinUI 3 Gallery app and see the ToggleSwitch in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source

> code on GitHub

Here's how to create a simple toggle switch. This XAML creates the toggle switch shown previously.

XAML

```
<ToggleSwitch x:Name="lightToggle" Header="Kitchen Lights"/>
```

Here's how to create the same toggle switch in code.

C#

```
ToggleSwitch lightToggle = new ToggleSwitch();
lightToggle.Header = "Kitchen Lights";

// Add the toggle switch to a parent container in the visual tree.
stackPanel1.Children.Add(lightToggle);
```

IsOn

The switch can be either on or off. Use the IsOn property to determine the state of the switch. When the switch is used to control the state of another binary property, you can use a binding as shown here.

XAML

```
<StackPanel Orientation="Horizontal">
    <ToggleSwitch x:Name="ToggleSwitch1" IsOn="True"/>
    <ProgressRing IsActive="{x:Bind ToggleSwitch1.IsOn, Mode=OneWay}"
                  Width="130"/>
</StackPanel>
```

Toggled

In other cases, you can handle the Toggled event to respond to changes in the state.

This example shows how to add a Toggled event handler in XAML and in code. The Toggled event is handled to turn a progress ring on or off, and change its visibility.

XAML

```
<ToggleSwitch x:Name="toggleSwitch1" IsOn="True"
```

```
                Toggled="ToggleSwitch_Toggled"/>
```

Here's how to create the same toggle switch in code.

C#

```
// Create a new toggle switch and add a Toggled event handler.
ToggleSwitch toggleSwitch1 = new ToggleSwitch();
toggleSwitch1.Toggled += ToggleSwitch_Toggled;

// Add the toggle switch to a parent container in the visual tree.
stackPanel1.Children.Add(toggleSwitch1);
```

Here's the handler for the Toggled event.

C#

```
private void ToggleSwitch_Toggled(object sender, RoutedEventArgs e)
{
    ToggleSwitch toggleSwitch = sender as ToggleSwitch;
    if (toggleSwitch != null)
    {
        if (toggleSwitch.IsOn == true)
        {
            progress1.IsActive = true;
            progress1.Visibility = Visibility.Visible;
        }
        else
        {
            progress1.IsActive = false;
            progress1.Visibility = Visibility.Collapsed;
        }
    }
}
```

On/Off labels

By default, the toggle switch includes literal On and Off labels, which are localized automatically. You can replace these labels by setting the OnContent, and OffContent properties.

This example replaces the On/Off labels with Show/Hide labels.

XAML

```
<ToggleSwitch x:Name="imageToggle" Header="Show images"
              OffContent="Show" OnContent="Hide"
```

```
                Toggled="ToggleSwitch_Toggled"/>
```

You can also use more complex content by setting the OnContentTemplate and OffContentTemplate properties.

UWP and WinUI 2

> **Important**
>
> The information and examples in this article are optimized for apps that use the **Windows App SDK** and **WinUI 3**, but are generally applicable to UWP apps that use **WinUI 2**. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

APIs for this control exist in the Windows.UI.Xaml.Controls namespace.

- ✓ **UWP APIs:** ToggleSwitch class, IsOn property, Toggled event
- ✓ Open the WinUI 2 Gallery app and see the Slider in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles and templates for all controls.

Collections and lists

Article • 10/31/2023

Collections and lists both refer to the representation of multiple related data items that appear together. Collections can be represented in multiple ways, by different collection controls (also may be referred to as collection views). Collection controls display and enable interactions with collection-based content, such as a list of contacts, a list of dates, a collection of images, and so on.

> **Important APIs**: ItemsView, ListView class, GridView class, FlipView class, TreeView class, ItemsRepeater class

The controls covered in this article include:

Expand table

Control	Primary use
ItemsView	to display collections using a flexible layout system
ListView	to display text-heavy content collections
GridView	to display image-heavy content collections
FlipView	to display image-heavy content collections that require exactly one item to be in focus at a time
TreeView	to display text-heavy content collections in a specific hierarchy
ItemsRepeater	as a customizable building block to create custom collection controls

Design guidelines, features, and examples are given below for each control.

Each of these controls (with the exception of ItemsRepeater) provide built-in styling and interaction. However, to further customize the visual look of your collection view and the items inside it, a DataTemplate is used. Detailed information on data templates and customizing the look of a collection view can be found on the Item containers and templates page.

Each of these controls (with the exception of ItemsRepeater) also have built-in behavior to allow for the selection of single or multiple items. See Selection modes overview to learn more.

One of the scenarios not covered in this article is displaying collections in a table or across multiple columns. If you're looking to display a collection in this format, consider using the DataGrid control from the Windows Community Toolkit.

Examples

Expand table

WinUI 2 Gallery	
	If you have the **WinUI 2 Gallery** app installed, see the ListView, GridView, FlipView, TreeView, and ItemsRepeater in action. • Get the WinUI 2 Gallery app (Microsoft Store) • Get the source code (GitHub)

Items view

You can use an items view to display text- or image-heavy data items in a variety of flexible layouts that can be swapped at run-time.

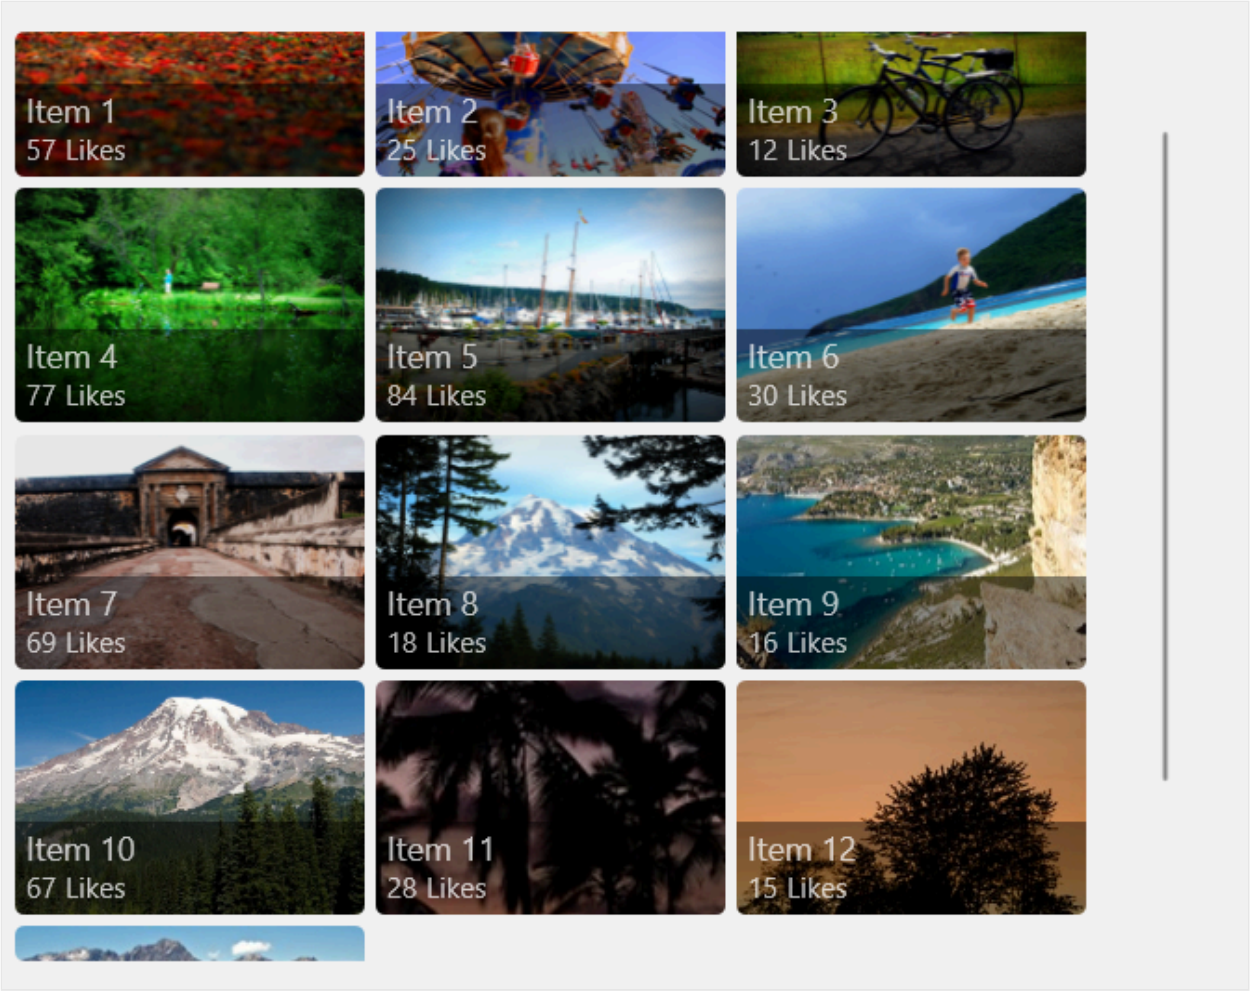
Is this the right control?

Use an items view to:

- Display a collection that primarily consists of text-based items, where all of the items should have the same visual and interaction behavior.
- Display a content collection in which the focal point of each item is an image, and each item should have the same visual and interaction behavior.
- Display content libraries.
- Accommodate a variety of use cases, including the following common ones:
  - Create a contacts list.
  - Storefront-type user interface (i.e. browsing apps, songs, products)
  - Interactive photo libraries

Examples

Here's an items view that shows a collection of photos in a uniform grid layout.



This is the same collection shown in a stack layout. The focus here is on the text rather than on the photo.

Topic	Description
Items view	Learn the essentials of using an items view in your app.
Item containers and templates	The items you display in a list or grid can play a major role in the overall look of your app. Make your app look great by customizing the look of your collection items through modifying control templates and data templates.

List view

List views represent text-heavy items, typically in a single-column, vertically-stacked layout. They let you categorize items and assign group headers, drag and drop items, curate content, and reorder items.

Is this the right control?

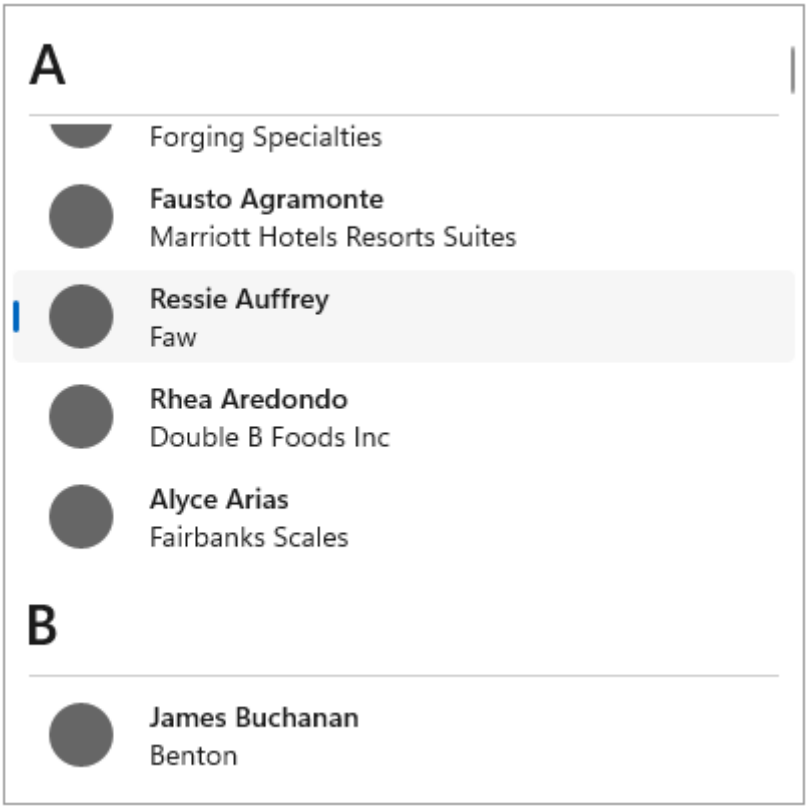
Use a list view to:

- Display a collection that primarily consists of text-based items, where all of the items should have the same visual and interaction behavior.
- Represent a single or categorized collection of content.
- Accommodate a variety of use cases, including the following common ones:
  - Create a list of messages or message log.
  - Create a contacts list.
  - Create the list pane in the list/details pattern. A list/details pattern is often used in email apps, in which one pane has a list of selectable items while the other pane (details) has a detailed view of the selected item.

> **Note**
>
> If you need to handle pointer events for a **UIElement** in a scrollable view (such as a ScrollViewer or ListView), you must explicitly disable support for manipulation events on the element in the view by calling **UIElement.CancelDirectmanipulation**. To re-enable manipulation events in the view, call **UIElement.TryStartDirectManipulation**.

Examples

Here's a simple list view that shows a contacts list, and groups the data items alphabetically. The group headers (each letter of the alphabet in this example) can also be customized to stay "sticky", as in they will always appear at the top of the ListView while scrolling.



This is a ListView that has been inverted to display a log of messages, with the newest messages appearing at the bottom. With an inverted ListView, items appear at the bottom of the screen with a built-in animation.

List view and grid view	Learn the essentials of using a list view or grid view in your app.
Item containers and templates	The items you display in a list or grid view can play a major role in the overall look of your app. Make your app look great by customizing the look of your collection items through modifying control templates and data templates.
Item templates for list view	Use these example item templates for a ListView to get the look of common app types.
Inverted lists	Inverted lists have new items added at the bottom, like in a chat app. Follow this article's guidance to use an inverted list in your app.
Pull-to-refresh	The pull-to-refresh mechanism lets a user pull down on a list of data using touch in order to retrieve more data. Use this article to implement pull-to-refresh in your list view.
Nested UI	Nested UI is a user interface (UI) that exposes actionable controls enclosed inside a container that a user can also take action on. For example, you might have list view item that contains a button, and the user can select the list item, or press the button nested within it. Follow these best practices to provide the best nested UI experience for your users.

Grid view

Grid views are suited for arranging and browsing image-based content collections. A grid view layout scrolls vertically and pans horizontally. Items are in a wrapped layout, as they appear in a left-to-right, then top-to-bottom reading order.

Is this the right control?

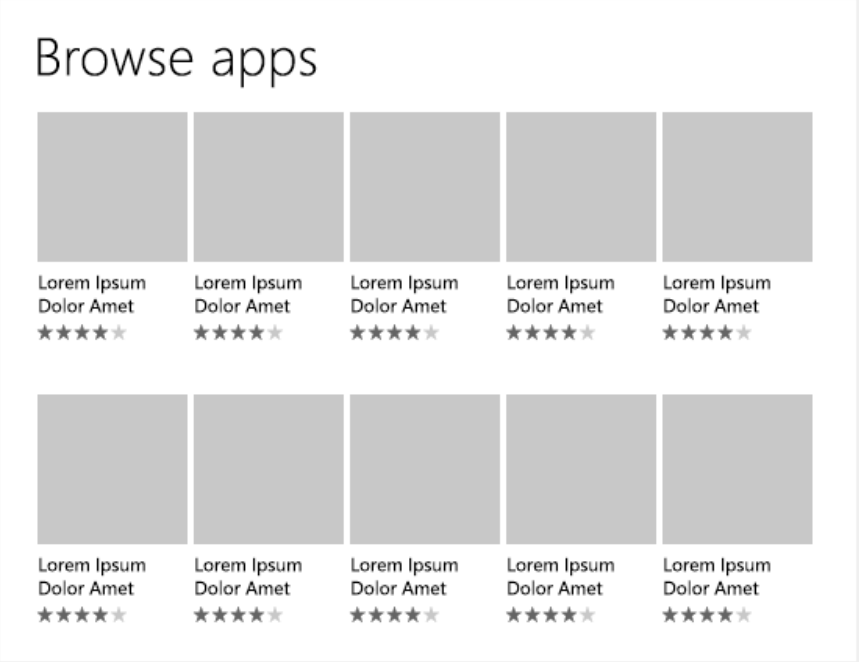
Use a grid view to:

- Display a content collection in which the focal point of each item is an image, and each item should have the same visual and interaction behavior.
- Display content libraries.
- Format the two content views associated with semantic zoom.
- Accommodate a variety of use cases, including the following common ones:
  - Storefront-type user interface (i.e. browsing apps, songs, products)
  - Interactive photo libraries

> **Note**
>
> If you need to handle pointer events for a **UIElement** in a scrollable view (such as a ScrollViewer or ListView), you must explicitly disable support for manipulation events on the element in the view by calling **UIElement.CancelDirectmanipulation()**. To re-enable manipulation events in the view, call **UIElement.TryStartDirectManipulation()**.

Examples

This example shows a typical grid view layout, in this case for browsing apps. Metadata for grid view items is usually restricted to a few lines of text and an item rating.



A grid view is an ideal solution for a content library, which is often used to present media such as pictures and videos. In a content library, users expect to be able to tap an item to invoke an action.

List view and grid view	Learn the essentials of using a list view or grid view in your app.
Item containers and templates	The items you display in a list or grid view can play a major role in the overall look of your app. Make your app look great by customizing the look of your collection items through modifying control templates and data templates.
Item templates for grid view	Use these example item templates for a ListView to get the look of common app types.
Nested UI	Nested UI is a user interface (UI) that exposes actionable controls enclosed inside a container that a user can also take action on. For example, you might have list view item that contains a button, and the user can select the list item, or press the button nested within it. Follow these best practices to provide the best nested UI experience for your users.

Flip view

Flip views are suited for browsing image-based content collections, specifically where the desired experience is for only one image to be visible at a time. A flip view allows the user to move or "flip" through the collection items (either vertically or horizontally), having each item appear one at a time after the user interaction.

Is this the right control?

Use a flip view to:

- Display a small to medium (less than 25 items) collection, where the collection is made up of images with little to no metadata.
- Display items one at a time, and allow the end-user to flip through the items at their own pace.
- Accommodate a variety of use cases, including the following common ones:
  - Photo galleries
  - Product galleries or showcases

Examples

The following two examples show a FlipView that flips horizontally and vertically, respectively.

Tree view

Tree views are suited for displaying text-based collections that have an important hierarchy that needs to be showcased. Tree view items are collapsible/expandable, are shown in a visual hierarchy, can be supplemented with icons, and can be dragged and dropped between tree views. Tree views allow for N-level nesting.

Is this the right control?

Use a tree view to:

- Display a collection of nested items whose context and meaning is dependent on a hierarchy or specific organizational chain.
- Accommodate a variety of use cases, including the following common ones:
  - File browser
  - Company organizational chart

Examples

Here is an example of a tree view that represents a file explorer, and displays many different nested items supplemented by icons.

Topic	Description
Tree view	Learn the essentials of using a tree view in your app, along with how to customize the look and interaction behavior of your items within a tree view.

ItemsRepeater

ItemsRepeater is different from the rest of the collection controls shown on this page because it does not provide any styling or interaction out-of-box, i.e. when simply placed on a page without defining any properties. ItemsRepeater is rather a building block that you as a developer can use to create your own custom collections control, specifically one that cannot be achieved by using the other controls in this article.

ItemsRepeater is a data-driven and high-performance panel that can be tailored to fit your exact needs.

> **Tip**
>
> The ItemsView control is built on top of ItemsRepeater and provides many of the benefits of ItemsRepeater without the need to create your own custom collection control.

Is this the right control?

Use an ItemsRepeater if:

- You have a specific user interface and user experience in mind that cannot be created using existing collection controls.
- You have an existing data source for your items (such as data pulled from the internet, a database, or a pre-existing collection in your code-behind).

Examples

The following three examples are all ItemsRepeater controls that are bound to the same data source (a collection of numbers). The collection of numbers is represented in three ways, with each of the ItemsRepeaters below using a different custom Layout and a different custom ItemTemplate.

Globalization and localization checklist

- **Wrapping**: Allow two lines for the list label.
- **Horizontal expansion**: Make sure fields can accommodate text expansion and are scrollable.
- **Vertical spacing**: Use non-Latin characters for vertical spacing to ensure non-Latin scripts will display properly.

Items view

Article • 10/31/2023

Use an items view to display a collection of data items, such as photos in an album or items in a product catalog.

The items view is similar to the list view and grid view controls, and you can use it in most cases where you would use those controls. One advantage of the items view is its ability to switch the layout on the fly while preserving item selection.

The items view control is built using the ItemsRepeater, ScrollView, ItemContainer, and ItemCollectionTransitionProvider components, so it offers the unique ability to plug in custom Layout or ItemCollectionTransitionProvider implementations. The item view's inner ScrollView control allows scrolling and zooming of the items. It also offers features unavailable in the ScrollViewer control used by the list view and grid view, like the ability to control the animation during programmatic scrolls.

Like the list view and grid view controls, the items view can use UI and data virtualization; handle keyboard, mouse, pen, and touch input; and has built-in accessibility support.

Is this the right control?

Use an items view to:

- Display a collection where all of the items should have the same visual and interaction behavior.
- Display a content collection with the ability to switch between list, grid, and custom layouts.
- Accommodate a variety of use cases, including the following common ones:
  - Storefront-type user interface (i.e. browsing apps, songs, products)
  - Interactive photo libraries
  - Contacts list

Create an items view

✓ Important APIs: ItemsView class, ItemsSource property, ItemTemplate property, LinedFlowLayout, StackLayout, UniformGridLayout

Open the WinUI 3 Gallery app and see the ItemsView in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

An ItemsView can show a collection of items of any type. To populate the view, set the ItemsSource property to a data source.

> **Note**
>
> Unlike other collection controls (those that derive from ItemsControl), ItemsView does not have an Items property that you can add data items to directly.

Set the items source

You typically use an items view to display data from a source such as a database or the internet. To populate an items view from a data source, you set its ItemsSource property to a collection of data items.

Set ItemsSource in code

Here, the ItemsSource is set in code directly to an instance of a collection.

C#

```
// Data source.
List<String> itemsList = new List<string>();
itemsList.Add("Item 1");
itemsList.Add("Item 2");

// Create a new ItemsView and set the data source.
ItemsView itemsView1 = new ItemsView();
itemsView1.ItemsSource = itemsList;

// Add the ItemsView to a parent container in the visual tree.
rootGrid.Children.Add(itemsView1);
```

Bind ItemsSource in XAML

You can also bind the ItemsSource property to a collection in XAML. For more info, see Data binding with XAML.

> **ⓘ Important**
>
> When you use the x:Bind markup extension in a DataTemplate, you have to specify the data type (`x:DataType`) on the data template.

Here, the ItemsSource is bound to a collection of custom data objects (of type `Photo`).

XAML

```
<ItemsView ItemsSource="{x:Bind Photos}">

</ItemsView>
```

C#

```
public sealed partial class MainPage : Page
{
    public MainPage()
    {
        this.InitializeComponent();
        Photos = new ObservableCollection<Photo>();
        PopulatePhotos();
    }

    public ObservableCollection<Photo> Photos
    {
        get; private set;
    }

    private void PopulatePhotos()
    {
        // Populate the Photos collection.
    }
}

public class Photo
{
    public BitmapImage PhotoBitmapImage { get; set; }
    public string Title { get; set; }
    public int Likes { get; set; }
}
```

Specify the look of the items

By default, a data item is displayed in the items view as the string representation of the data object it's bound to. You typically want to show a more rich presentation of your

data. To specify exactly how items in the items view are displayed, you create a DataTemplate. The XAML in the DataTemplate defines the layout and appearance of controls used to display an individual item. The controls in the layout can be bound to properties of a data object, or have static content defined inline. The DataTemplate is assigned to the ItemTemplate property of the ItemsView control.

> **Important**
>
> The root element of the DataTemplate must be an **ItemContainer**; otherwise, an exception is thrown. ItemContainer is an independent primitive control that is used by ItemsView to show the selection states and other visualizations of an individual item in the item collection.

In this example, the DataTemplate is defined in the `Page.Resources` ResourceDictionary. It includes an Image control to show the picture and an overlay that contains the image title and number of likes it's received.

XAML

```
 <Page.Resources>
     <DataTemplate x:Key="PhotoItemTemplate" x:DataType="local:Photo">
         <ItemContainer AutomationProperties.Name="{x:Bind Title}">
             <Grid>
                 <Image Source="{x:Bind PhotoBitmapImage, Mode=OneWay}"
                        Stretch="UniformToFill" MinWidth="70"
                        HorizontalAlignment="Center"
VerticalAlignment="Center"/>
                 <StackPanel Orientation="Vertical" Height="40"
Opacity=".75"
                             VerticalAlignment="Bottom" Padding="5,1,5,1"
                             Background="{ThemeResource
SystemControlBackgroundBaseMediumBrush}">
                     <TextBlock Text="{x:Bind Title}"
                                Foreground="{ThemeResource
SystemControlForegroundAltHighBrush}"/>
                     <StackPanel Orientation="Horizontal">
                         <TextBlock Text="{x:Bind Likes}"
                                    Style="{ThemeResource
CaptionTextBlockStyle}"
                                    Foreground="{ThemeResource
SystemControlForegroundAltHighBrush}"/>
                         <TextBlock Text=" Likes"
                                    Style="{ThemeResource
CaptionTextBlockStyle}"
                                    Foreground="{ThemeResource
SystemControlForegroundAltHighBrush}"/>
                     </StackPanel>
                 </StackPanel>
```

```
            </Grid>
        </ItemContainer>
    </DataTemplate>
</Page.Resources>

<Grid x:Name="rootGrid">
    <ItemsView ItemsSource="{x:Bind Photos}" Width="480" Height="400"
               ItemTemplate="{StaticResource PhotoItemTemplate}">
    </ItemsView>
</Grid>
```

Here's what the item layout defined by the data template looks like.

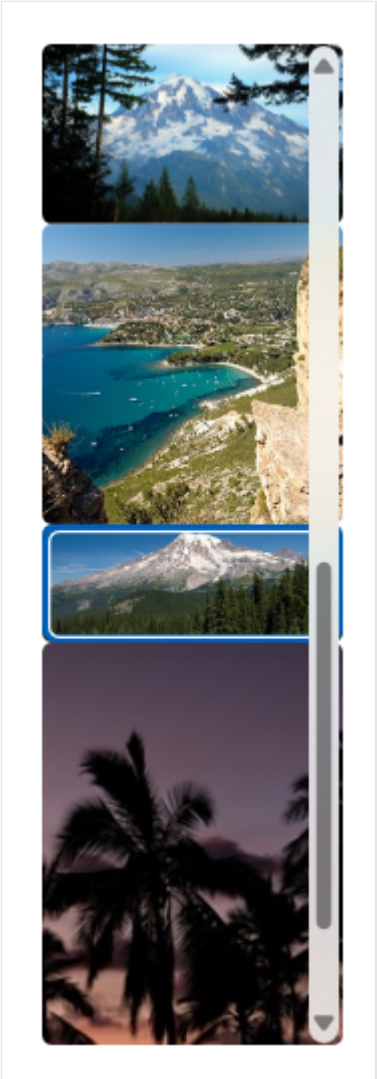
Change the layout of items

When you add items to an ItemsView control, it automatically wraps each item in an ItemContainer and then lays out all of the item containers. How these item containers are laid out depends on the Layout property of the control.

You can modify the layout of items by adjusting the properties on the current layout, or you can completely replace the current layout with a different layout. You can use one of the layouts described next, or you can derive a custom layout from the Layout class.

StackLayout

By default, ItemsView uses a StackLayout, which produces a vertical list, shown here with default property settings and a simple image template.



This XAML sets the spacing between items in the StackLayout to 5px.

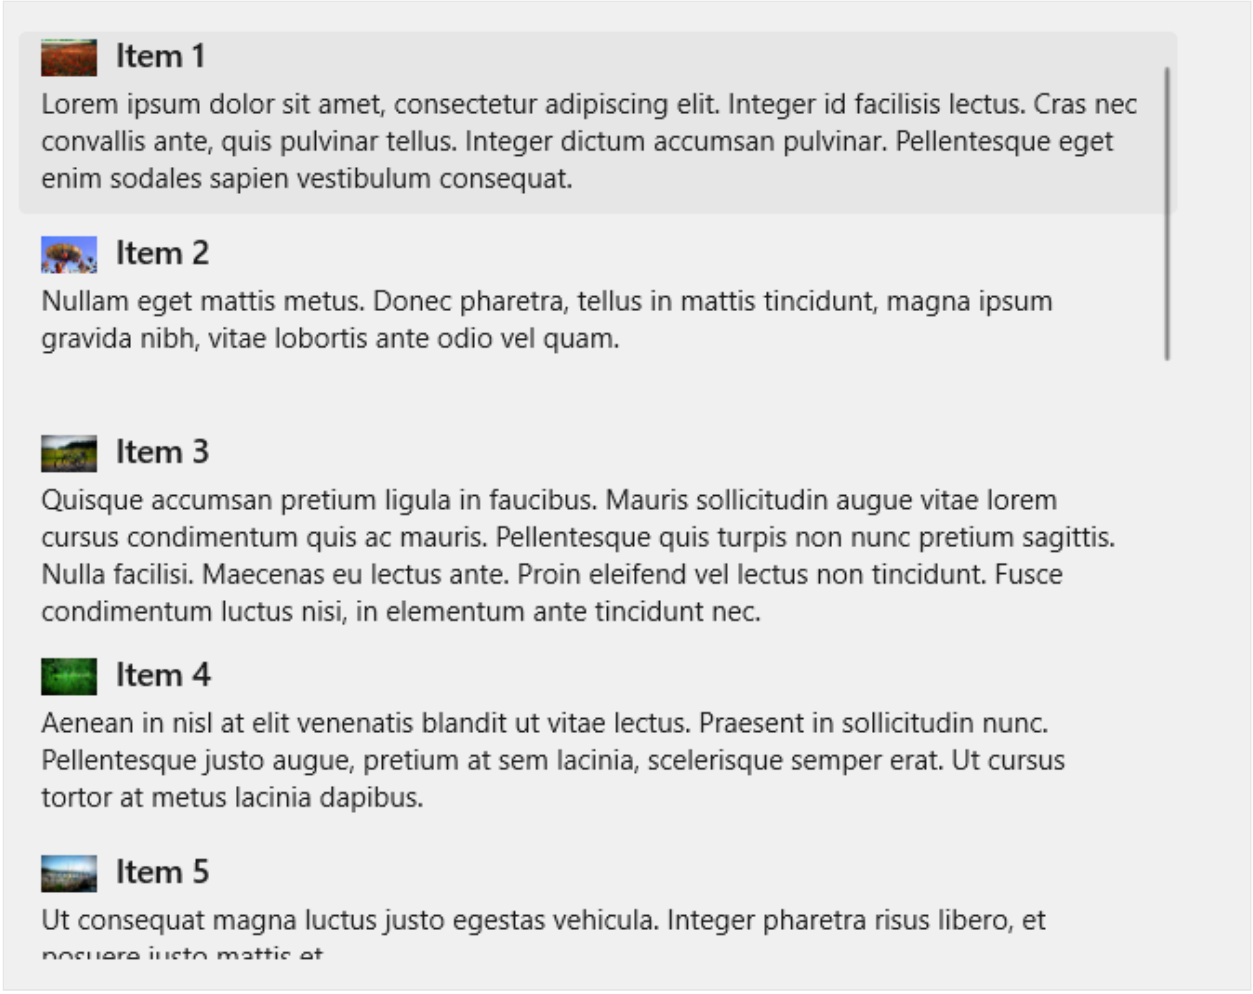
XAML

```
<ItemsView ItemsSource="{x:Bind Photos}" Width="480" Height="400"
           ItemTemplate="{StaticResource PhotoItemTemplate}">
    <ItemsView.Layout>
        <StackLayout Spacing="5"/>
    </ItemsView.Layout>
</ItemsView>
```

StackLayout provides properties to control:

- whether the layout is vertical or horizontal (Orientation)
- the spacing of items (Spacing)

You can use the layout in combination with the ItemTemplate to give your collection a variety of looks to suit your needs. For example, the WinUI Gallery sample changes the ItemTemplate used with the StackLayout to look like this.



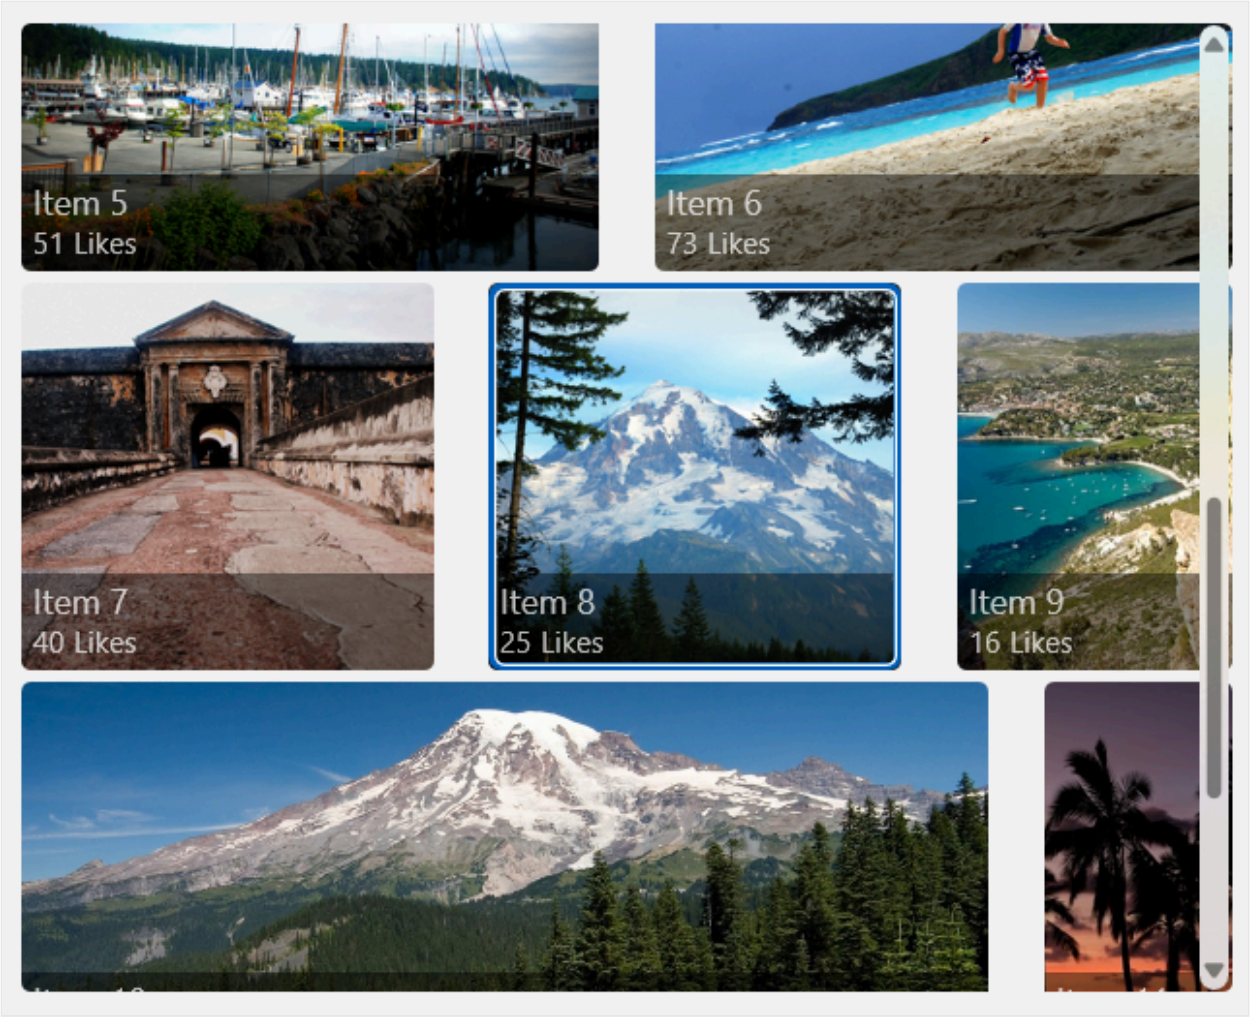
LinedFlowLayout

The LinedFlowLayout positions elements sequentially from left to right, then top to bottom, in a wrapping layout. Use this layout to display an item collection where the items have a fixed height but a variable width. We recommend it for image based collections. This layout also has built-in animations that play when the collection has items added or removed, and when the view is resized.

Here's an items view that shows a collection of photos in a lined flow layout.

XAML

```
<ItemsView Width="500" Height="400" HorizontalAlignment="Left"
           ItemTemplate="{StaticResource LinedFlowLayoutItemTemplate}">
    <ItemsView.Layout>
        <LinedFlowLayout ItemsStretch="Fill"
                         LineHeight="160"
                         LineSpacing="5"
                         MinItemSpacing="5"/>
    </ItemsView.Layout>
</ItemsView>
```



LinedFlowLayout provides properties to control:

- the size and spacing of items (LineHeight, LineSpacing, MinItemSpacing)
- the arrangement of items (ItemsJustification, ItemsStretch)

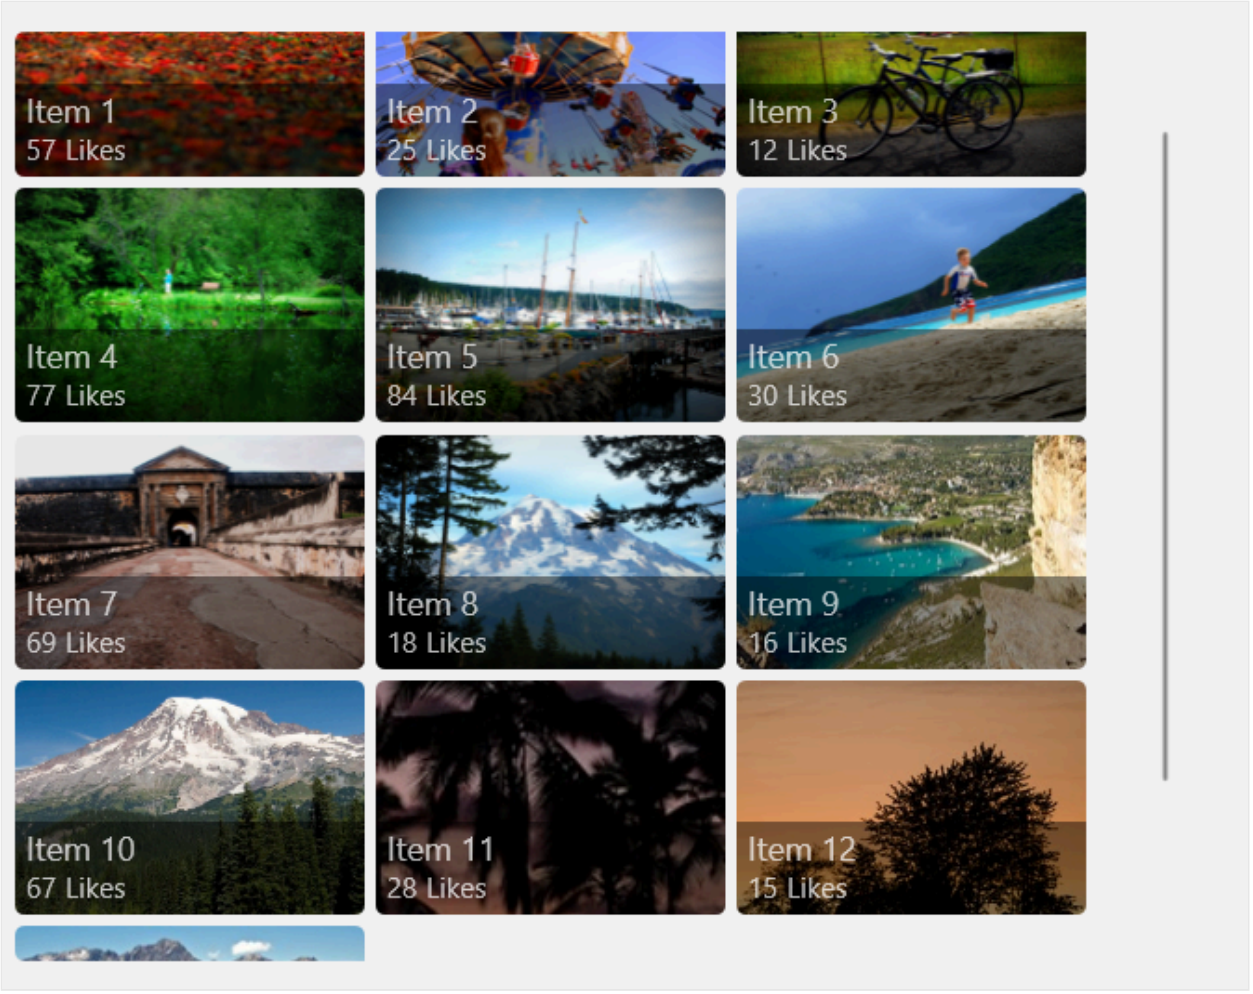
UniformGridLayout

The UniformGridLayout positions elements sequentially from left to right or top to bottom (depending on the Orientation) in a wrapping layout. Each item is the same size.

Here's an items view that shows a collection of photos in a uniform grid layout.

XAML

```
<ItemsView ItemsSource="{x:Bind Photos}" Width="480" Height="400"
           ItemTemplate="{StaticResource PhotoItemTemplate}">
    <ItemsView.Layout>
        <UniformGridLayout MaximumRowsOrColumns="3"
                           MinRowSpacing="5"
                           MinColumnSpacing="5"/>
    </ItemsView.Layout>
</ItemsView>
```



UniformGridLayout provides properties to control:

- whether the layout is row or column based (Orientation)
- the number of rows or columns (MaximumRowsOrColumns)
- the size and spacing of items (MinItemHeight, MinItemWidth, MinColumnSpacing, MinRowSpacing)
- the arrangement of items (ItemsJustification, ItemsStretch)

> **Tip**
>
> Use the interactive demo in the **WinUI 3 Gallery app** to see the effect of these properties in real time.

Item selection and interaction

You can choose from a variety of ways to let users interact with an items view. By default, users can select a single item. You can change the SelectionMode property to enable multi-selection or to disable selection. You can set the IsItemInvokedEnabled property so that users click an item to invoke an action instead of selecting the item.

This table shows the ways a user can interact with an items view, and how you can respond to the interaction.

Expand table

To enable this interaction:	Use these settings:	Handle this event:	Use this property to get the selected item:
No interaction	SelectionMode="None" IsItemInvokedEnabled="False"	N/A	N/A
Single selection	SelectionMode="Single" IsItemInvokedEnabled="False"	SelectionChanged	SelectedItem
Multiple selection	SelectionMode="Multiple" IsItemInvokedEnabled="False"	SelectionChanged	SelectedItems
Extended selection	SelectionMode="Extended" IsItemInvokedEnabled="False"	SelectionChanged	SelectedItems
Click	SelectionMode="None" IsItemInvokedEnabled="True"	ItemInvoked	N/A

> **Note**
>
> You can enable IsItemInvokedEnabled to raise an ItemInvoked event while SelectionMode is also set to `Single`, `Multiple`, or `Extended`. If you do this, the ItemInvoked event is raised first, and then the SelectionChanged event is raised. In some cases (for example, if you go to another page in the ItemInvoked event handler), the SelectionChanged event isn't raised and the item isn't selected.

You can set these properties in XAML or in code, as shown here:

XAML

```
<ItemsView x:Name="myItemsView" SelectionMode="None"
IsItemInvokedEnabled="True"/>
```

C#

```
myItemsView.SelectionMode = ItemsViewSelectionMode.None;
myItemsView.IsItemInvokedEnabled = true;
```

Read-only

You can set the SelectionMode property to ItemsViewSelectionMode.None to disable item selection. This puts the control in read-only mode, so that it's used for displaying data, but not for interacting with it. That is, the item selection is disabled, but the control itself is not.

> **Note**
>
> Items can still be selected and deselected programmatically, but not through user interaction.

Single selection

This table describes keyboard, mouse, and touch interactions when SelectionMode is set to `Single`.

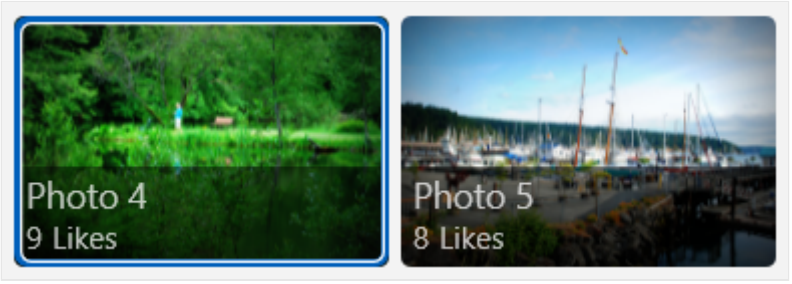
Expand table

Modifier key	Interaction
None	• Users can select a single item by using the space bar, mouse clicks, or taps.
Ctrl	• Users can deselect a single item by using the space bar, mouse clicks, or taps. • By using the arrow keys, users can move the focus independent of the selection.

When SelectionMode is set to `Single`, you can get the selected data item from the SelectedItem property. If no item is selected, SelectedItem is `null`.

If you try to set an item that's not in the items collection as SelectedItem, the operation is ignored and SelectedItem is `null`.

The default selection indicator for `Single` selection looks like this.



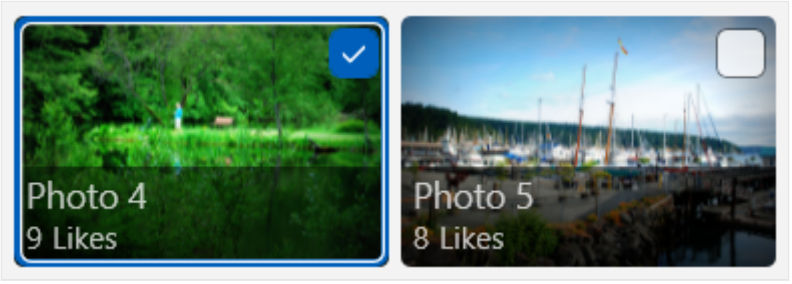
Multiple selection

This table describes the keyboard, mouse, and touch interactions when SelectionMode is set to `Multiple`.

Expand table

Modifier key	Interaction
None	• Users can select multiple items by using the space bar, mouse clicks, or taps to select the focused item. • By using the arrow keys, users can move the focus independent of their selection.
Shift	• Users can select multiple contiguous items by clicking or tapping the first item in the selection and then clicking or tapping the last item in the selection. • By using the arrow keys, users can select contiguous items starting with the item that's selected when they select the Shift key.

The default selection indicator for `Multiple` selection looks like this.



Extended selection

This table describes the keyboard, mouse, and touch interactions when SelectionMode is set to `Extended`.

Expand table

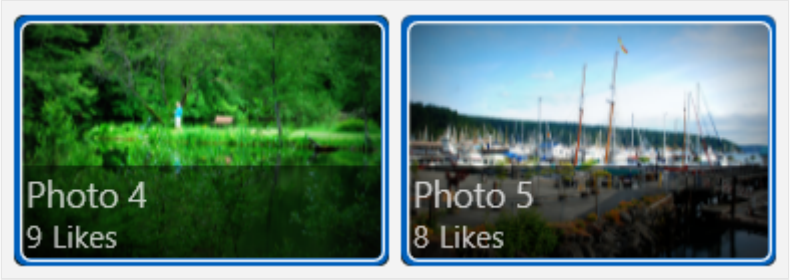
Modifier key	Interaction
None	• The behavior is the same as `Single` selection.
Ctrl	• Users can select multiple items by using the space bar, mouse clicks, or taps to select the focused item. • By using the arrow keys, users can move the focus independent of the selection.
Shift	• Users can select multiple contiguous items by clicking or tapping the first item in the selection and then clicking or tapping the last item in the selection.

Modifier key	Interaction
	• By using the arrow keys, users can select contiguous items starting with the item that's selected when they select the Shift key.

When SelectionMode is set to `Multiple` or `Extended`, you can get the selected data items from the SelectedItems property.

The SelectedItem and SelectedItems properties are synchronized. For example, if you set SelectedItem to `null`, SelectedItems is empty. In multi-select mode, SelectedItem contains the item that was selected first.

The default selection indicator for `Extended` selection is the same as for `Single` selection and looks like this.



Manage item selection programmatically

> **Note**
>
> These selection methods ignore the SelectionMode property and have an effect even when SelectionMode is `Single` or `None`.

Sometimes, you might need to manipulate the ItemsView item selection programmatically. For example, you might display a Select all button to let users select all items in a list. In this case, it's usually not very efficient to add and remove items from the SelectedItems collection one by one. It's more efficient to use the Select, SelectAll, Deselect, and InvertSelection methods to modify the selection than to use the SelectedItems property.

> **Tip**

You can select all items in a collection by calling the SelectAll method. There is no corresponding method to deselect all items. However, you can deselect all items by calling SelectAll followed immediately by InvertSelection.

List view and grid view

Article • 02/26/2025

Most applications manipulate and display sets of data, such as a gallery of images or a set of email messages. The XAML UI framework provides ListView and GridView controls that make it easy to display and manipulate data in your app.

> **Note**
>
> ListView and GridView both derive from the **ListViewBase** class, so they have the same functionality but display data differently. In this article, discussions about *list view* apply to both the ListView and GridView controls, unless otherwise specified. We may refer to classes like ListView or ListViewItem, but the *List* prefix can be replaced with *Grid* for the corresponding grid equivalent (GridView or GridViewItem).

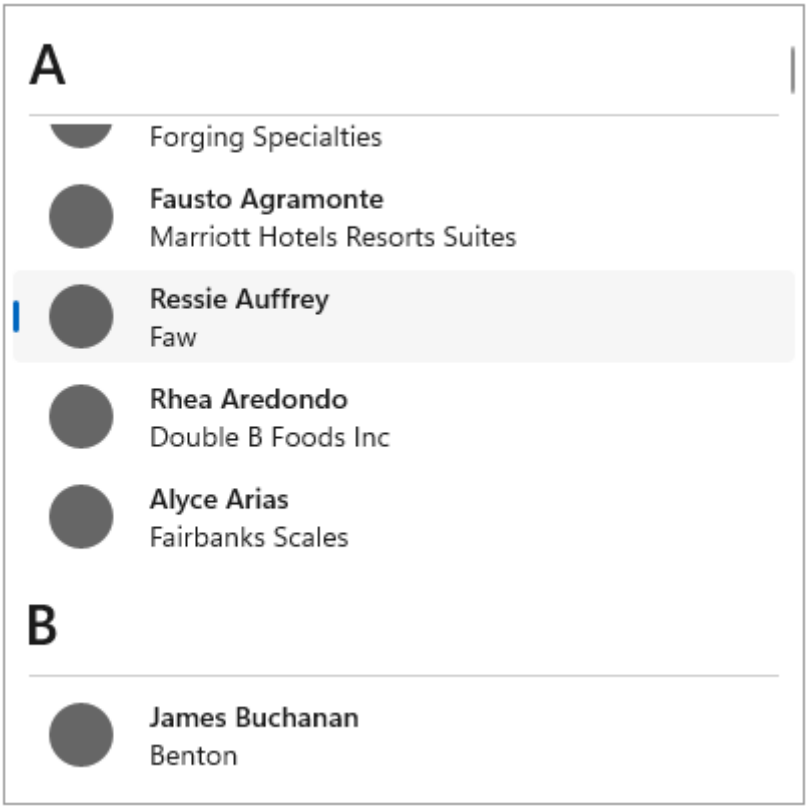
ListView and GridView controls provide many benefits as you work with collections. Both are easy to implement and provide basic UI, interaction, and scrolling while being easily customizable. And both can be bound to existing dynamic data sources or to hard-coded data that's provided in the XAML itself or the code-behind.

Both controls are flexible to use in a variety of scenarios but, overall, they work best with collections in which all items have the same basic structure and appearance, as well as the same interaction behavior. That is, they all should perform the same action when they're clicked (for example, to open a link or browse).

Compare ListView and GridView

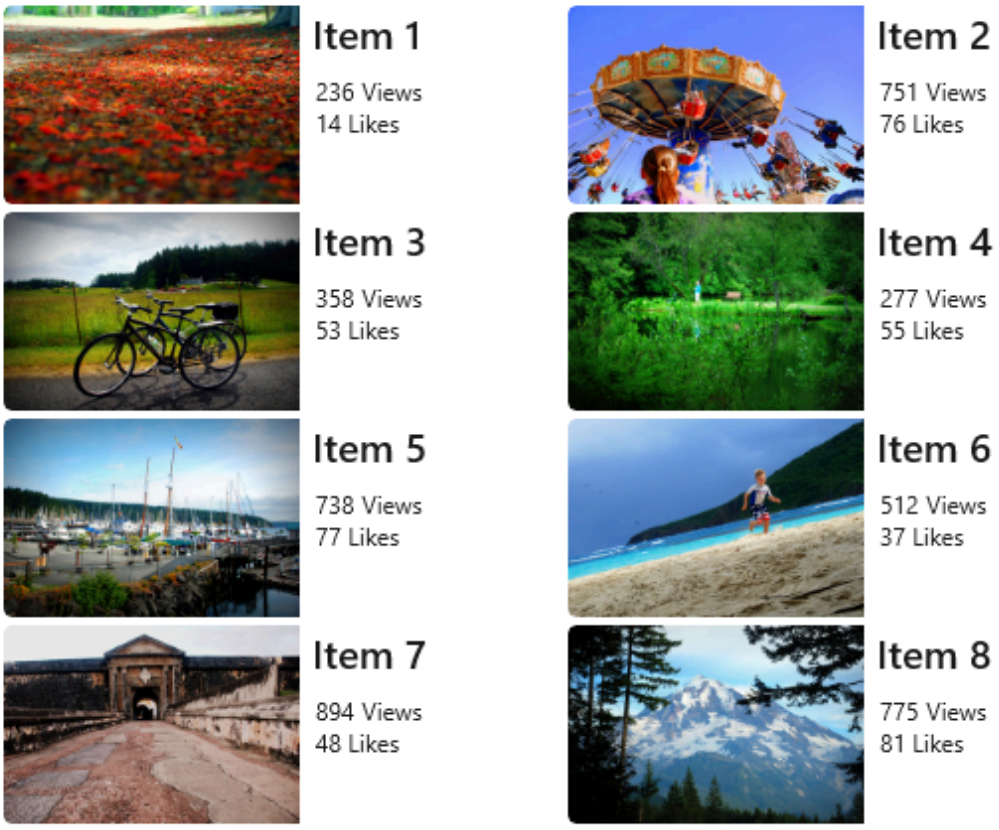
ListView

The ListView control displays data stacked vertically in a single column. ListView works better for items that have text as a focal point, and for collections that are meant to be read top to bottom (for example, alphabetically ordered). A few common use cases for ListView include lists of messages and search results. If you need to display collections in multiple columns or in a table-like format, you should *not* use ListView. Instead, consider using a DataGrid control.



GridView

The GridView control presents a collection of items in rows and columns that can be scrolled vertically. Data is stacked horizontally until it fills a column, and then continues with the next row in the column. GridView works better for collections that have images as their focal point or whose items can be read from side-to-side or are not sorted in a specific order. A common use case for GridView is a photo or product gallery.



Which collection control should you use? A Comparison with ItemsRepeater

It's important to understand the differences between these types of controls before you decide which one to use.

ListView and GridView

The feature-rich ListView and GridView controls work *out of box*. They require no customization, but they can be customized easily. Each has its own built-in UI and UX and is designed to display nearly any type of collection as is.

ItemsRepeater

The ItemsRepeater control also is used to display collections, but it's designed as a building block for creating a custom control to suit your particular UI requirements. It doesn't have the same built-in features and functionality as ListView and GridView, so you'll need to implement any necessary features or interactions. Use ItemsRepeater if

you have a highly customized UI that you can't create by using either ListView or GridView, or if your data source requires different behavior for each item.

Learn more about ItemsRepeater by reading its Guidelines and API documentation.

Create a list view or a grid view

✔ **Important APIs**: ListView class, GridView class, ItemsSource property, Items property

Open the WinUI 3 Gallery app and see the **ListView** or the **GridView** in action.

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

ListView and GridView are both ItemsControl types, so they can contain a collection of items of any type. A ListView or GridView control must have items in its Items collection before it can display anything on the screen. To populate the view, you can add items directly to the collection or set the ItemsSource property to a data source.

> ⊗ **Caution**
>
> You can use either the Items or ItemsSource property to populate the list, but you can't use both at the same time. If you set the ItemsSource property and you add an item in XAML, the added item is ignored. If you set the ItemsSource property and you add an item to the Items collection in code, an exception is thrown.

Many of the examples in this article populate the Items collection directly for the sake of simplicity. However, it's more common for the items in a list to come from a dynamic source, such as a list of books from an online database. You use the ItemsSource property for this purpose.

Add items to a ListView or GridView control

You can add items to the ListView or GridView Items collection by using either XAML or code to yield the same result. You would ordinarily add items through XAML if you have a small number of items that don't change and are easily defined, or if you generate the items in code at runtime.

Method 1: Add items to the Items collection

- Option 1: Add items through XAML

```
XAML

<!-- No corresponding C# code is needed for this example. -->

<ListView x:Name="Fruits">
<x:String>Apricot</x:String>
<x:String>Banana</x:String>
<x:String>Cherry</x:String>
<x:String>Orange</x:String>
<x:String>Strawberry</x:String>
</ListView>
```

- Option 2: Add items through code

```
XAML

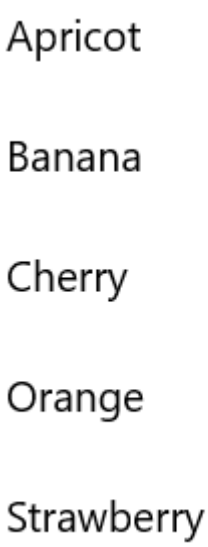
<StackPanel Name="FruitsPanel"></StackPanel>
```

```
C#

// Create a new ListView and add content.
ListView Fruits = new ListView();
Fruits.Items.Add("Apricot");
Fruits.Items.Add("Banana");
Fruits.Items.Add("Cherry");
Fruits.Items.Add("Orange");
Fruits.Items.Add("Strawberry");

// Add the ListView to a parent container in the visual tree (which you
created in the corresponding XAML file).
FruitsPanel.Children.Add(Fruits);
```

Both of these options produce the same list view, as shown here:



Method 2: Add items by setting the ItemsSource property

You would ordinarily use a ListView or GridView to display data from a source such as a database or the internet. To populate a ListView or GridView control from a data source, you set its ItemsSource property to a collection of data items. This method works better if ListView or GridView is going to hold custom class objects, as shown in the following examples.

- Option 1: Set ItemsSource in code

  Here, the ListView ItemsSource property is set in code directly to an instance of a collection.

  XAML

  ```
  <StackPanel x:Name="ContactPanel"></StackPanel>
  ```

  C#

  ```
  // Class definition should be provided within the namespace being used,
  outside of any other classes.

  this.InitializeComponent();

  // Instead of adding hard coded items to an ObservableCollection as
  shown here,
  //the data could be pulled asynchronously from a database or the
  internet.
  ObservableCollection<Contact> Contacts = new
  ObservableCollection<Contact>();

  // You create Contact objects by providing a first name, last name, and
  company for the Contact constructor.
  ```

```
// They are then added to the ObservableCollection Contacts.
Contacts.Add(new Contact("John", "Doe", "Contoso, LTD."));
Contacts.Add(new Contact("Jane", "Doe", "Fabrikam, Inc."));
Contacts.Add(new Contact("Santa", "Claus", "Alpine Ski House"));

// Create a new ListView (or GridView) for the UI, and add content by
setting ItemsSource
ListView ContactsLV = new ListView();
ContactsLV.ItemsSource = Contacts;

// Add the ListView to a parent container in the visual tree (which you
created in the corresponding XAML file)
ContactPanel.Children.Add(ContactsLV);
```

- Option 2: Set ItemsSource in XAML

  You can also bind the ItemsSource property to a collection in the XAML. Here, ItemsSource is bound to a public property named Contacts, which exposes the page's private data collection, named *_contacts*.

XAML

```
<ListView x:Name="ContactsLV" ItemsSource="{x:Bind Contacts}"/>
```

C#

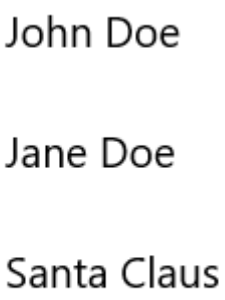
```
// Provide a class definition within the namespace being used, outside
of any other classes.
// These two declarations belong outside the main page class.
private ObservableCollection<Contact> _contacts = new
ObservableCollection<Contact>();

public ObservableCollection<Contact> Contacts
{
    get { return this._contacts; }
}

// Define this method within your main page class.
protected override void OnNavigatedTo(NavigationEventArgs e)
{
    base.OnNavigatedTo(e);

    // Instead of hard coded items, the data could be pulled
    // asynchronously from a database or the internet.
    Contacts.Add(new Contact("John", "Doe", "Contoso, LTD."));
    Contacts.Add(new Contact("Jane", "Doe", "Fabrikam, Inc."));
    Contacts.Add(new Contact("Santa", "Claus", "Alpine Ski House"));
}
```

Both of these options will produce the same list view, as shown in the following screenshot. (The list view shows the string representation of each item, because a data template isn't defined for this exercise.)



> **Important**
>
> Without a defined data template, custom class objects will appear in the list view with their string value only if they have a defined ToString method.

The next section goes into greater detail about how to visually represent simple and custom class items properly in a ListView or GridView template.

For more info about data binding, see Data binding overview.

> **Note**
>
> If you need to show grouped data in your list view, you must bind to a CollectionViewSource class. CollectionViewSource acts as a proxy for the collection class in XAML and enables grouping support. For more info, see CollectionViewSource.

Customize the look with a data template

By using a data template in a ListView or GridView control, you can define how the items and data are to be visualized. By default, a data item is displayed in the list view as the string representation of the data object it's bound to. You can show the string representation of a particular property of the data item by setting DisplayMemberPath to that property.

However, you might ordinarily want to show a richer presentation of your data. To specify how items in the list view or grid view are to be displayed, you create a

DataTemplate class. The XAML in DataTemplate defines the layout and appearance of the controls that are used to display an individual item. The controls in the layout can be bound to the properties of a data object, or they can have static content that's defined inline.

> **ⓘ Important**
>
> When you use the x:Bind markup extension in DataTemplate, you have to specify the data type (`x:DataType`) on the data template.

A simple ListView data template

In this example, the data item is a simple string. To add an image to the left of the string, and to display the string in teal, you define DataTemplate inline within the ListView definition. This is the same ListView control that you created earlier by using option 1 under method 1.

XAML

```
<!--No corresponding code is needed for this example.-->
<ListView x:Name="FruitsList">
                <ListView.ItemTemplate>
                    <DataTemplate x:DataType="x:String">
                        <Grid>
                            <Grid.ColumnDefinitions>
                                <ColumnDefinition Width="47"/>
                                <ColumnDefinition/>
                            </Grid.ColumnDefinitions>
                            <Image Source="Assets/placeholder.png"
Width="32" Height="32"
                                HorizontalAlignment="Left"
VerticalAlignment="Center"/>
                            <TextBlock Text="{x:Bind}" Foreground="Teal"
FontSize="14"
                                Grid.Column="1" VerticalAlignment="Center"/>
                        </Grid>
                    </DataTemplate>
                </ListView.ItemTemplate>
                <x:String>Apricot</x:String>
                <x:String>Banana</x:String>
                <x:String>Cherry</x:String>
                <x:String>Orange</x:String>
                <x:String>Strawberry</x:String>
            </ListView>
```

Here's how the data items are displayed when you apply a simple ListView data template:

A ListView data template for custom class objects

In the following example, the data item is a Contact object. To add the contact image to the left of the Contact name and company, you define DataTemplate inline within the ListView definition. This ListView data template was created in option 2 under method 2, as shown earlier.

XAML

```
<ListView x:Name="ContactsLV" ItemsSource="{x:Bind Contacts}">
    <ListView.ItemTemplate>
        <DataTemplate x:DataType="local:Contact">
            <Grid>
                <Grid.RowDefinitions>
                    <RowDefinition Height="*"/>
                    <RowDefinition Height="*"/>
                </Grid.RowDefinitions>
                <Grid.ColumnDefinitions>
                    <ColumnDefinition Width="Auto"/>
                    <ColumnDefinition Width="*"/>
                </Grid.ColumnDefinitions>
                <Image Grid.Column="0" Grid.RowSpan="2" Source="Assets/grey-
placeholder.png" Width="32"
                    Height="32" HorizontalAlignment="Center"
VerticalAlignment="Center"></Image>
                <TextBlock Grid.Column="1" Text="{x:Bind Name}"
Margin="12,6,0,0"
                    Style="{ThemeResource BaseTextBlockStyle}"/>
                <TextBlock  Grid.Column="1" Grid.Row="1" Text="{x:Bind
Company}" Margin="12,0,0,6"
```

```
                    Style="{ThemeResource BodyTextBlockStyle}"/>
            </Grid>
        </DataTemplate>
    </ListView.ItemTemplate>
</ListView>
```

Here's how the data items are displayed when you apply a ListView data template for custom class objects:

Data templates are the primary way you define the look of your ListView. They can also significantly affect performance if your list holds a large number of items.

You can define your data template inline within the ListView or GridView definition, as shown in the preceding code, or separately in a Resources section. If you define it outside the ListView or GridView definition, you must give the data template an x:Key attribute and assign it to the ItemTemplate property of the ListView or GridView by using that key.

For more info and examples of how to use data templates and item containers to define the look of items in your list or grid, see Item containers and templates.

Change the layout of items

When you add items to a ListView or GridView control, it automatically wraps each item in an item container and then lays out all of the item containers. How these item containers are laid out depends on the ItemsPanel property of the control.

- **ListView**, by default, uses ItemsStackPanel, which produces a vertical list:

Item 1

Item 2

Item 3

Item 4

Item 5

- **GridView** uses ItemsWrapGrid, which adds items horizontally, and wraps and scrolls vertically:

Item 1 Item 2 Item 3

Item 4 Item 5

You can modify the layout of items by adjusting the properties on the items panel, or you can replace the default panel with another panel.

> ⓘ **Note**
>
> If you change ItemsPanel, do *not* disable virtualization. Both ItemsStackPanel and ItemsWrapGrid support virtualization, so these classes are safe to use. If you use any other panel, you might disable virtualization and slow the performance of the list view. For more info, see the list view articles under **Performance**.

This example shows how to make a ListView control lay out its item containers in a horizontal list by changing the Orientation property of ItemsStackPanel.

Because the list view scrolls vertically, by default, you also need to adjust some properties on the list view's internal ScrollViewer to make it scroll horizontally.

- Change ScrollViewer.HorizontalScrollMode to **Enabled** or **Auto**.
- Change ScrollViewer.HorizontalScrollBarVisibility to **Auto**.
- Change ScrollViewer.VerticalScrollMode to **Disabled**.
- Change ScrollViewer.VerticalScrollBarVisibility to **Hidden**.

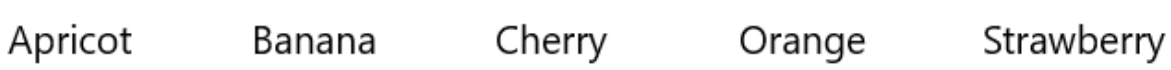
> ⓘ **Important**
>
> The following examples are shown with the list view width unconstrained, so the horizontal scrollbars aren't displayed. If you run this code, you can set `Width="180"`

for ListView to display the scrollbars.

XAML

```
<ListView Height="60"
          ScrollViewer.HorizontalScrollMode="Enabled"
          ScrollViewer.HorizontalScrollBarVisibility="Auto"
          ScrollViewer.VerticalScrollMode="Disabled"
          ScrollViewer.VerticalScrollBarVisibility="Hidden">
    <ListView.ItemsPanel>
        <ItemsPanelTemplate>
            <ItemsStackPanel Orientation="Horizontal"/>
        </ItemsPanelTemplate>
    </ListView.ItemsPanel>
    <x:String>Apricot</x:String>
    <x:String>Banana</x:String>
    <x:String>Cherry</x:String>
    <x:String>Orange</x:String>
    <x:String>Strawberry</x:String>
</ListView>
```

Here's how the list is displayed:



In the next example, ListView lays out items in a vertical wrapping list by using ItemsWrapGrid instead of ItemsStackPanel.

ⓘ Important

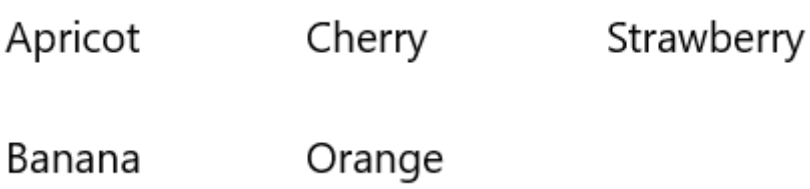
You must constrain the height of the list view to force the control to wrap the containers.

XAML

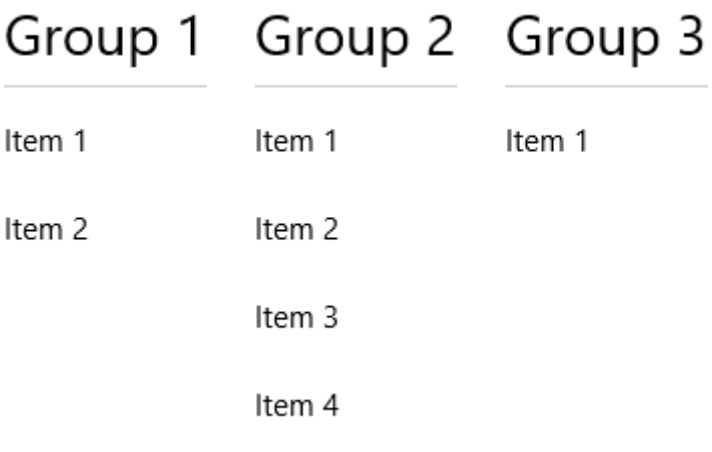
```
<ListView Height="100"
          ScrollViewer.HorizontalScrollMode="Enabled"
          ScrollViewer.HorizontalScrollBarVisibility="Auto"
          ScrollViewer.VerticalScrollMode="Disabled"
          ScrollViewer.VerticalScrollBarVisibility="Hidden">
    <ListView.ItemsPanel>
        <ItemsPanelTemplate>
            <ItemsWrapGrid/>
        </ItemsPanelTemplate>
    </ListView.ItemsPanel>
    <x:String>Apricot</x:String>
```

```
    <x:String>Banana</x:String>
    <x:String>Cherry</x:String>
    <x:String>Orange</x:String>
    <x:String>Strawberry</x:String>
</ListView>
```

Here's how the list is displayed:



If you show grouped data in your list view, ItemsPanel determines how the item groups are laid out, not how the individual items are laid out. For example, if you use the previously shown horizontal ItemsStackPanel to show grouped data, the groups are arranged horizontally, but the items in each group are still stacked vertically, as shown here:



Item selection and interaction

You can choose from a variety of ways to let users interact with a list view. By default, users can select a single item. You can change the SelectionMode property to enable multi-selection or to disable selection. You can set the IsItemClickEnabled property so that users click an item (for example, a button) to invoke an action instead of selecting the item.

> ⓘ **Note**
>
> Both ListView and GridView use the ListViewSelectionMode enumeration for their SelectionMode properties. IsItemClickEnabled is set to **False** by default, so you

need only to set it to enable click mode.

This table shows the ways a user can interact with a list view, and how you can respond to the interaction.

Expand table

To enable this interaction:	Use these settings:	Handle this event:	Use this property to get the selected item:
No interaction	SelectionMode="None" IsItemClickEnabled="False"	N/A	N/A
Single selection	SelectionMode="Single" IsItemClickEnabled="False"	SelectionChanged	SelectedItem SelectedIndex
Multiple selection	SelectionMode="Multiple" IsItemClickEnabled="False"	SelectionChanged	SelectedItems
Extended selection	SelectionMode="Extended" IsItemClickEnabled="False"	SelectionChanged	SelectedItems
Click	SelectionMode="None" IsItemClickEnabled="True"	ItemClick	N/A

> **Note**
>
> You can enable IsItemClickEnabled to raise an ItemClick event while SelectionMode is also set to **Single**, **Multiple**, or **Extended**. If you do this, the ItemClick event is raised first, and then the SelectionChanged event is raised. In some cases (for example, if you go to another page in the ItemClick event handler), the SelectionChanged event isn't raised and the item isn't selected.

You can set these properties in XAML or in code, as shown here:

XAML

```
<ListView x:Name="myListView" SelectionMode="Multiple"/>

<GridView x:Name="myGridView" SelectionMode="None"
IsItemClickEnabled="True"/>
```

C#

```
myListView.SelectionMode = ListViewSelectionMode.Multiple;

myGridView.SelectionMode = ListViewSelectionMode.None;
myGridView.IsItemClickEnabled = true;
```

Read-only

You can set the SelectionMode property to **ListViewSelectionMode.None** to disable item selection. This puts the control in read-only mode, so that it's used for displaying data, but not for interacting with it. That is, the item selection is disabled, but the control itself is not.

Single selection

This table describes keyboard, mouse, and touch interactions when SelectionMode is set to **Single**.

Expand table

Modifier key	Interaction
None	• Users can select a single item by using the space bar, mouse clicks, or taps.
Ctrl	• Users can deselect a single item by using the space bar, mouse clicks, or taps. • By using the arrow keys, users can move the focus independent of the selection.

When SelectionMode is set to **Single**, you can get the selected data item from the SelectedItem property. You can get the index in the collection of the selected item by using the SelectedIndex property. If no item is selected, SelectedItem is **null**, and SelectedIndex is -1.

If you try to set an item that's not in the Items collection as SelectedItem, the operation is ignored and SelectedItem is **null**. However, if you try to set SelectedIndex to an index that's out of the range of the items in the list, a System.ArgumentException exception occurs.

Multiple selection

This table describes the keyboard, mouse, and touch interactions when SelectionMode is set to **Multiple**.

Expand table

Modifier key	Interaction
None	• Users can select multiple items by using the space bar, mouse clicks, or taps to select the focused item. • By using the arrow keys, users can move the focus independent of their selection.
Shift	• Users can select multiple contiguous items by clicking or tapping the first item in the selection and then clicking or tapping the last item in the selection. • By using the arrow keys, users can select contiguous items starting with the item that's selected when they select the Shift key.

Extended selection

This table describes the keyboard, mouse, and touch interactions when SelectionMode is set to **Extended**.

Expand table

Modifier key	Interaction
None	• The behavior is the same as **Single** selection.
Ctrl	• Users can select multiple items by using the space bar, mouse clicks, or taps to select the focused item. • By using the arrow keys, users can move the focus independent of the selection.
Shift	• Users can select multiple contiguous items by clicking or tapping the first item in the selection and then clicking or tapping the last item in the selection. • By using the arrow keys, users can select contiguous items starting with the item that's selected when they select the Shift key.

When SelectionMode is set to **Multiple** or **Extended**, you can get the selected data items from the SelectedItems property.

The SelectedIndex, SelectedItem, and SelectedItems properties are synchronized. For example, if you set SelectedIndex to -1, SelectedItem is set to **null** and SelectedItems is empty. And if you set SelectedItem to **null**, SelectedIndex is set to -1 and SelectedItems is empty.

In multi-select mode, SelectedItem contains the item that was selected first, and Selectedindex contains the index of the item that was selected first.

Respond to selection changes

To respond to selection changes in a list view, handle the SelectionChanged event. In the event handler code, you can get the list of selected items from the SelectionChangedEventArgs.AddedItems property. You can get any items that were deselected from the SelectionChangedEventArgs.RemovedItems property. The AddedItems and RemovedItems collections contain at most one item, unless users select a range of items by holding down the Shift key.

The following example shows how to handle the SelectionChanged event and access the various Item collections:

XAML

```
<StackPanel HorizontalAlignment="Right">
    <ListView x:Name="listView1" SelectionMode="Multiple"
              SelectionChanged="ListView1_SelectionChanged">
        <x:String>Apricot</x:String>
        <x:String>Banana</x:String>
        <x:String>Cherry</x:String>
        <x:String>Orange</x:String>
        <x:String>Strawberry</x:String>
    </ListView>
    <TextBlock x:Name="selectedItem"/>
    <TextBlock x:Name="selectedIndex"/>
    <TextBlock x:Name="selectedItemCount"/>
    <TextBlock x:Name="addedItems"/>
    <TextBlock x:Name="removedItems"/>
</StackPanel>
```

C#

```
private void ListView1_SelectionChanged(object sender,
SelectionChangedEventArgs e)
{
    if (listView1.SelectedItem != null)
    {
        selectedItem.Text =
            "Selected item: " + listView1.SelectedItem.ToString();
    }
    else
    {
        selectedItem.Text =
            "Selected item: null";
    }
    selectedIndex.Text =
        "Selected index: " + listView1.SelectedIndex.ToString();
    selectedItemCount.Text =
        "Items selected: " + listView1.SelectedItems.Count.ToString();
    addedItems.Text =
```

```
        "Added: " + e.AddedItems.Count.ToString();
    removedItems.Text =
        "Removed: " + e.RemovedItems.Count.ToString();
}
```

Click mode

You can change a list view so that users click buttons and other items instead of selecting them. For example, this is useful if your app opens a new page when users click an item in a list or grid.

To enable this behavior:

- Set SelectionMode to **None**.
- Set IsItemClickEnabled to **True**.
- Handle the ItemClick event to do something when users click an item.

Here's a list view with clickable items. The code in the ItemClick event handler opens a new page in the app.

XAML

```
<ListView SelectionMode="None"
          IsItemClickEnabled="True"
          ItemClick="ListView1_ItemClick">
    <x:String>Page 1</x:String>
    <x:String>Page 2</x:String>
    <x:String>Page 3</x:String>
    <x:String>Page 4</x:String>
    <x:String>Page 5</x:String>
</ListView>
```

C#

```
private void ListView1_ItemClick(object sender, ItemClickEventArgs e)
{
    switch (e.ClickedItem.ToString())
    {
        case "Page 1":
            this.Frame.Navigate(typeof(Page1));
            break;

        case "Page 2":
            this.Frame.Navigate(typeof(Page2));
            break;

        case "Page 3":
            this.Frame.Navigate(typeof(Page3));
```

```
            break;

        case "Page 4":
            this.Frame.Navigate(typeof(Page4));
            break;

        case "Page 5":
            this.Frame.Navigate(typeof(Page5));
            break;

        default:
            break;
    }
}
```

Select a range of items programmatically

Sometimes, you might need to manipulate a ListView item selection programmatically. For example, you might display a **Select all** button to let users select all items in a list. In this case, it's usually not very efficient to add and remove items from the SelectedItems collection one by one. Each item change causes a SelectionChanged event, and when you work with the items directly instead of working with index values, the item is de-virtualized.

It's more efficient to use the SelectAll, SelectRange, and DeselectRange methods to modify the selection than to use the SelectedItems property. These methods select (or deselect) items by using ranges of item indexes. Items that are virtualized remain virtualized, because only the index is used. All items in the specified range are selected (or deselected), regardless of their original selection state. The SelectionChanged event occurs only once for each call to these methods.

> **ⓘ Important**
>
> You should call these methods only when the SelectionMode property is set to **Multiple** or **Extended**. If you call SelectRange when SelectionMode is **Single** or **None**, an exception is thrown.

When you select items by using index ranges, use the SelectedRanges property to get all selected ranges in the list.

If the ItemsSource property implements IItemsRangeInfo, and you use these methods to modify the selection, the AddedItems and RemovedItems properties aren't set in SelectionChangedEventArgs. Setting these properties requires de-virtualizing the item object. Use the SelectedRanges property to get the items instead.

You can select all items in a collection by calling the SelectAll method. However, there is no corresponding method to deselect all items. You can deselect all items by calling DeselectRange and passing an ItemIndexRange with a FirstIndex value of 0 and a Length value equal to the number of items in the collection. This is shown in the following example, along with an option to select all items.

XAML

```
<StackPanel Width="160">
    <Button Content="Select all" Click="SelectAllButton_Click"/>
    <Button Content="Deselect all" Click="DeselectAllButton_Click"/>
    <ListView x:Name="listView1" SelectionMode="Multiple">
        <x:String>Apricot</x:String>
        <x:String>Banana</x:String>
        <x:String>Cherry</x:String>
        <x:String>Orange</x:String>
        <x:String>Strawberry</x:String>
    </ListView>
</StackPanel>
```

C#

```
private void SelectAllButton_Click(object sender, RoutedEventArgs e)
{
    if (listView1.SelectionMode == ListViewSelectionMode.Multiple ||
        listView1.SelectionMode == ListViewSelectionMode.Extended)
    {
        listView1.SelectAll();
    }
}

private void DeselectAllButton_Click(object sender, RoutedEventArgs e)
{
    if (listView1.SelectionMode == ListViewSelectionMode.Multiple ||
        listView1.SelectionMode == ListViewSelectionMode.Extended)
    {
        listView1.DeselectRange(new ItemIndexRange(0,
(uint)listView1.Items.Count));
    }
}
```

For info about how to change the look of selected items, see Item containers and templates.

Drag and drop

ListView and GridView controls support dragging and dropping items within their own controls, and between themselves and other ListView and GridView controls. For more

info about implementing drag and drop functionality, see Drag and drop.

UWP and WinUI 2

> **Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

APIs for these controls exist in the Windows.UI.Xaml.Controls namespace.

- ✓ **UWP APIs:** ListView class, GridView class, ItemsSource property, Items property
- ✓ Open the WinUI 2 Gallery app and see the ListView or the GridView in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

Get the sample code

- XAML ListView and GridView sample: Demonstrates the ListView and GridView controls.
- XAML drag and drop sample: Demonstrates drag and drop with the ListView control.

We recommend using the latest WinUI 2 to get the most current styles and templates for all controls.

Flip view

Article • 02/26/2025

Use a flip view for browsing images or other items in a collection, such as photos in an album or items in a product details page, one item at a time. For touch devices, swiping across an item moves through the collection. For a mouse, navigation buttons appear on mouse hover. For a keyboard, arrow keys move through the collection.

Is this the right control?

Flip view is best for perusing images in small to medium collections (up to 25 or so items). Examples of such collections include items in a product details page or photos in a photo album. Although we don't recommend flip view for most large collections, the control is common for viewing individual images in a photo album.

Recommendations

- Flip views work best for collections of up to 25 or so items.
- Avoid using a flip view control for larger collections, as the repetitive motion of flipping through each item can be tedious. An exception would be for photo albums, which often have hundreds or thousands of images. Photo albums almost always switch to a flip view once a photo has been selected in the grid view layout. For other large collections, consider a List view or grid view.

Globalization and localization checklist

- **Bi-directional considerations**: Use standard mirroring for RTL languages. The back and forward controls should be based on the language's direction, so for RTL languages, the right button should navigate backwards and the left button should navigate forward.

Examples

Horizontal browsing, starting at the left-most item and flipping right, is the typical layout for a flip view. This layout works well in either portrait or landscape orientation on all devices:

A flip view can also be browsed vertically:

Create a flip view

✓ **Important APIs**: FlipView class, ItemsSource property, ItemTemplate property

Open the WinUI 3 Gallery app and see the FlipView in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

FlipView is an ItemsControl, so it can contain a collection of items of any type. To populate the view, add items to the **Items** collection, or set the **ItemsSource** property to a data source.

By default, a data item is displayed in the flip view as the string representation of the data object it's bound to. To specify exactly how items in the flip view are displayed, you create a **DataTemplate** to define the layout of controls used to display an individual item. The controls in the layout can be bound to properties of a data object, or have content defined inline. You assign the DataTemplate to the **ItemTemplate** property of the FlipView.

Add items to the Items collection

You can add items to the **Items** collection using XAML or code. You typically add items this way if you have a small number of items that don't change and are easily defined in XAML, or if you generate the items in code at run time. Here's a flip view with items defined inline.

XAML

```
<FlipView x:Name="flipView1">
    <Image Source="Assets/Logo.png" />
    <Image Source="Assets/SplashScreen.png" />
    <Image Source="Assets/SmallLogo.png" />
</FlipView>
```

C#

```
// Create a new flip view, add content,
// and add a SelectionChanged event handler.
FlipView flipView1 = new FlipView();
flipView1.Items.Add("Item 1");
flipView1.Items.Add("Item 2");

// Add the flip view to a parent container in the visual tree.
stackPanel1.Children.Add(flipView1);
```

When you add items to a flip view they are automatically placed in a **FlipViewItem** container. To change how an item is displayed you can apply a style to the item container by setting the **ItemContainerStyle** property.

When you define the items in XAML, they are automatically added to the Items collection.

Set the items source

You typically use a flip view to display data from a source such as a database or the Internet. To populate a flip view from a data source, you set its **ItemsSource** property to a collection of data items.

Here, the flip view's ItemsSource is set in code directly to an instance of a collection.

C#

```
// Data source.
List<String> itemsList = new List<string>();
itemsList.Add("Item 1");
itemsList.Add("Item 2");

// Create a new flip view, add content,
// and add a SelectionChanged event handler.
FlipView flipView1 = new FlipView();
flipView1.ItemsSource = itemsList;
flipView1.SelectionChanged += FlipView_SelectionChanged;

// Add the flip view to a parent container in the visual tree.
stackPanel1.Children.Add(flipView1);
```

You can also bind the ItemsSource property to a collection in XAML. For more info, see Data binding with XAML.

Here, the ItemsSource is bound to a **CollectionViewSource** named `itemsViewSource`.

XAML

```
<Page.Resources>
    <!-- Collection of items displayed by this page -->
    <CollectionViewSource x:Name="itemsViewSource" Source="{Binding
Items}"/>
</Page.Resources>

...

<FlipView x:Name="itemFlipView"
          ItemsSource="{Binding Source={StaticResource itemsViewSource}}"/>
```

⊗ Caution

You can populate a flip view either by adding items to its Items collection, or by setting its ItemsSource property, but you can't use both ways at the same time. If you set the ItemsSource property and you add an item in XAML, the added item is

ignored. If you set the ItemsSource property and you add an item to the Items collection in code, an exception is thrown.

Specify the look of the items

By default, a data item is displayed in the flip view as the string representation of the data object it's bound to. You typically want to show a more rich presentation of your data. To specify exactly how items in the flip view are displayed, you create a **DataTemplate**. The XAML in the DataTemplate defines the layout and appearance of controls used to display an individual item. The controls in the layout can be bound to properties of a data object, or have content defined inline. The DataTemplate is assigned to the **ItemTemplate** property of the FlipView control.

In this example, the ItemTemplate of a FlipView is defined inline. An overlay is added to the image to display the image name.

XAML

```
<FlipView MaxWidth="400" Height="180" BorderBrush="Black"
BorderThickness="1"
          ItemsSource="{x:Bind Items, Mode=OneWay}">
    <FlipView.ItemTemplate>
        <DataTemplate x:DataType="data:ControlInfoDataItem">
            <Grid>
                <Grid.RowDefinitions>
                    <RowDefinition Height="*" />
                    <RowDefinition Height="Auto" />
                </Grid.RowDefinitions>
                <Image Width="36" Source="{x:Bind ImagePath}"
Stretch="Uniform"
                       VerticalAlignment="Center" />
                <Border Background="#A5FFFFFF" Height="60" Grid.Row="1">
                    <TextBlock x:Name="Control2Text" Text="{x:Bind Title}"
Foreground="Black"
                               Padding="12,12" Style="{StaticResource
TitleTextBlockStyle}"
                               HorizontalAlignment="Center" />
                </Border>
            </Grid>
        </DataTemplate>
    </FlipView.ItemTemplate>
</FlipView>
```

Here's what the layout defined by the data template looks like.

Set the orientation of the flip view

By default, the flip view flips horizontally. To make the it flip vertically, use a stack panel with a vertical orientation as the flip view's **ItemsPanel**.

This example shows how to use a stack panel with a vertical orientation as the ItemsPanel of a FlipView.

XAML

```
<FlipView x:Name="flipViewVertical" Width="480" Height="270"
          BorderBrush="Black" BorderThickness="1">

    <!-- Use a vertical stack panel for vertical flipping. -->
    <FlipView.ItemsPanel>
        <ItemsPanelTemplate>
            <VirtualizingStackPanel Orientation="Vertical"/>
        </ItemsPanelTemplate>
    </FlipView.ItemsPanel>

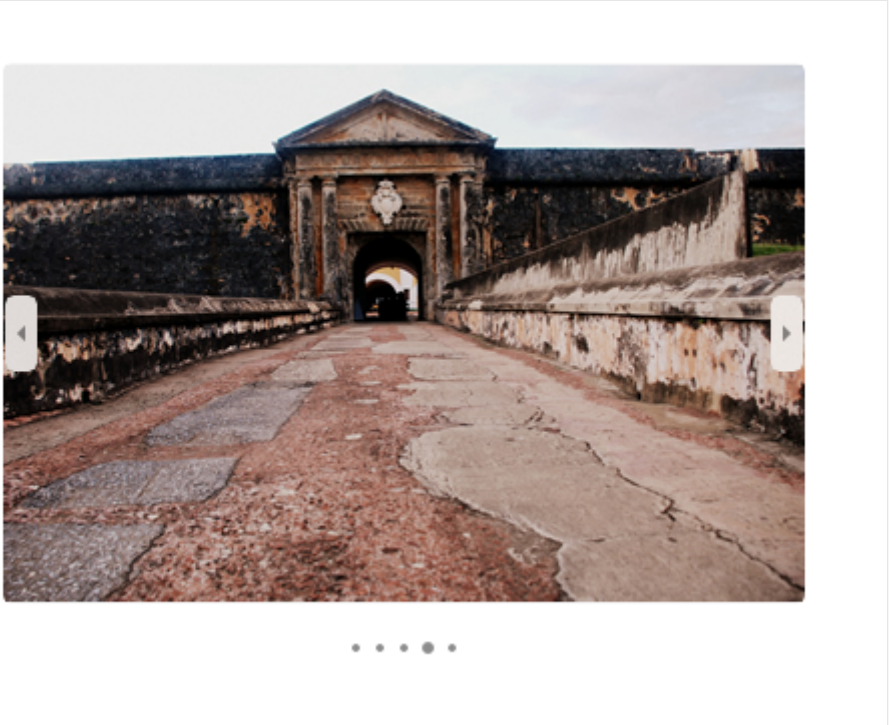
    <FlipView.ItemTemplate>
        <DataTemplate>
            <Grid>
                <Image Width="480" Height="270" Stretch="UniformToFill"
                       Source="{Binding Image}"/>
                <Border Background="#A5000000" Height="80"
VerticalAlignment="Bottom">
                    <TextBlock Text="{Binding Name}"
                               FontFamily="Segoe UI" FontSize="26.667"
                               Foreground="#CCFFFFFF" Padding="15,20"/>
                </Border>
            </Grid>
        </DataTemplate>
    </FlipView.ItemTemplate>
</FlipView>
```

Here's what the flip view looks like with a vertical orientation.

Adding a context indicator

Use a context indicator (such as a PipsPager or film strip) with a flip view to help provide users with a point of reference within the content.

The following image shows a PipsPager used with a small photo gallery (we recommend centering the PipsPager below the gallery).



This code snippet shows how to bind a PipsPager with a FlipView.

XAML

```
<StackPanel>
  <FlipView x:Name="Gallery" MaxWidth="400" Height="270" ItemsSource="
{x:Bind Pictures}">
      <FlipView.ItemTemplate>
          <DataTemplate x:DataType="x:String">
              <Image Source="{x:Bind Mode=OneWay}"/>
          </DataTemplate>
      </FlipView.ItemTemplate>
  </FlipView>

  <!-- The SelectedPageIndex is bound to the FlipView to keep the two in
sync -->
  <PipsPager x:Name="FlipViewPipsPager"
      HorizontalAlignment="Center"
      Margin="0, 10, 0, 0"
      NumberOfPages="{x:Bind Pictures.Count}"
      SelectedPageIndex="{x:Bind Path=Gallery.SelectedIndex, Mode=TwoWay}"
/>
</StackPanel>
```

For larger collections (10 or more items), we highly recommend using a contextual indicator such as a film strip of thumbnails. Unlike a PipsPager that uses simple dots or glyphs, each thumbnail in the film strip shows a smaller, selectable version of the corresponding image.

For a full example showing how to add a context indicator to a FlipView, see XAML FlipView sample.

UWP and WinUI 2

> **Important**
>
> The information and examples in this article are optimized for apps that use the **Windows App SDK** and **WinUI 3**, but are generally applicable to UWP apps that use **WinUI 2**. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

APIs for this control exist in the Windows.UI.Xaml.Controls namespace.

- ✓ **UWP APIs:** FlipView class, ItemsSource property, ItemTemplate property
- ✓ Open the WinUI 2 Gallery app and see the FlipView in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles and templates for all controls. WinUI 2.2 or later includes a new template for this control that uses rounded corners. For more info, see Corner radius.

PipsPager

Article • 02/26/2025

The PipsPager control helps users navigate within linearly paginated content using a configurable collection of glyphs, each of which represents a single "page" within a limitless range. The glyphs highlight the current page, and indicate the availability of both preceding and succeeding pages. The control relies on current context and does not support explicit page numbering or a non-linear organization.

What is a pip?

Pips represent a unit of numerical value, typically rendered as dots. However they can be customized to use other glyphs such as dashes or squares.

By default, each solid dot in the PipsPager control represents a page in the content layout. A user can select a dot to navigate to that page in the content.

Is this the right control?

Use a PipsPager for content organized in a linear structure, is not explicitly numbered, or where a glyph-based representation of numbered pages is desired.

This UI is commonly used in apps such as photo viewers and app lists, where display space is limited and the number of potential pages is infinite.

Recommendations

- Common UI patterns for a PipsPager include photo viewers, app lists, carousels, and layouts where display space is limited.
- For experiences optimized for gamepad input, we recommend against placing UI directly to the left or right of a horizontal PipsPager, and above or below a vertically oriented PipsPager.
- For experiences optimized for touch input, we recommend integrating the PipsPager with a view control, such as a FlipView, to take advantage of on-content pagination with touch (the user can also use touch to select individual pips).

Create a PipsPager

✔ **Important APIs**: PipsPager class

Open the WinUI 3 Gallery app and see the PipsPager in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

A default PipsPager is comprised of five visible pips that can be oriented horizontally (default) or vertically.

A PipsPager also supports navigation buttons (previous, next) to move to an incrementally adjacent page. By default, the navigation buttons are collapsed and do not take up layout space.

Wrapping between the first and last items is not supported.

XAML

```
<PipsPager x:Name="DefaultPipsPager" />
```

Horizontal PipsPager with navigation buttons

The navigation buttons (previous, next) let the user move to an incrementally adjacent page.

By default, the navigation buttons are collapsed. You can control this behavior through the PreviousButtonVisibility and NextButtonVisibility properties.

Possible values for these properties are:

- Collapsed: The button is not visible to the user and **does not** take up layout space. (Default)

- Visible: The button is visible and enabled. Each button is automatically hidden when the PipsPager is at the minimum or maximum extent of the content. For example, if the current page is the first page then the previous button is hidden; if the current page is the last page then the next button is hidden. When hidden, the button is not visible but **does** take up layout space.
- VisibleOnPointerOver: The behavior is the same as Visible *except* that the button is only displayed when the user hovers the pointer cursor over the PipsPager UI, or the user sets keyboard focus on the PipsPager.

XAML

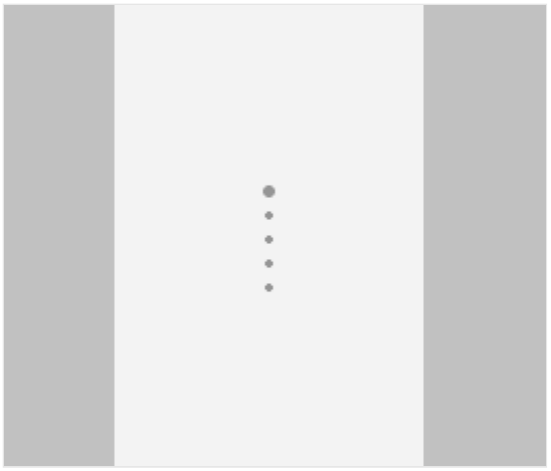
```
<PipsPager x:Name="VisibleButtonPipsPager"
    NumberOfPages="5"
    PreviousButtonVisibility="Visible"
    NextButtonVisibility="Visible" />
```

Vertical PipsPager with navigation buttons visible on pointer over

The PipsPager can be oriented vertically with no change to behavior or interaction experience.

The top button corresponds to the first button and the bottom button corresponds to the last button in the horizontal view.

The following example demonstrates the VisibleOnPointerOver setting for the navigation buttons.



XAML

```
<PipsPager x:Name="VerticalPipsPager"
    NumberOfPages="5"
    Orientation="Vertical"
    PreviousButtonVisibility="VisibleOnPointerOver"
    NextButtonVisibility="VisibleOnPointerOver" />
```

Scrolling pips

If the content consists of a large number of pages (NumberOfPages), you can use the MaxVisiblePips property to set the number of visible, interactive pips.

If the value of NumberOfPages is greater than the value of MaxVisiblePips, the pips automatically scroll in order to center the selected page in the control. If the NumberOfPages is equal to or less than MaxVisiblePips, no scrolling occurs and the number of pips shown is the same as the value of NumberOfPages.

If the value of MaxVisiblePips is greater than the available layout space, the displayed pips are clipped. The number of pips displayed is the lesser of MaxVisiblePips and NumberOfPages.

By default, a maximum of five pips are visible.

XAML

```
<PipsPager x:Name="ScrollingPipsPager"
    NumberOfPages="20"
    MaxVisiblePips="10" />
```

Integrate PipsPager with a Collection control

A PipsPager is often used in conjunction with collection controls.

The following example shows how to bind a PipsPager with a FlipView and provide another way to navigate through content and indicate the current page.

> ⓘ **Note**
>
> To use the PipsPager as a page indicator **only** and disable user interactions, set the control's IsEnabled property to false in the control.

XAML

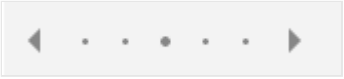
```
<StackPanel>
  <FlipView x:Name="Gallery" MaxWidth="400" Height="270" ItemsSource="
{x:Bind Pictures}">
      <FlipView.ItemTemplate>
          <DataTemplate x:DataType="x:String">
              <Image Source="{x:Bind Mode=OneWay}"/>
          </DataTemplate>
      </FlipView.ItemTemplate>
  </FlipView>
```

```
  <!-- The SelectedPageIndex is bound to the FlipView to keep the two in
sync -->
  <PipsPager x:Name="FlipViewPipsPager"
      HorizontalAlignment="Center"
      Margin="0, 10, 0, 0"
      NumberOfPages="{x:Bind Pictures.Count}"
      SelectedPageIndex="{x:Bind Path=Gallery.SelectedIndex, Mode=TwoWay}"
/>
</StackPanel>
```

Pip and navigation button customization

The navigation buttons and pips can be customized through the PreviousButtonStyle, NextButtonStyle, SelectedPipStyle, and NormalPipStyle properties.

If you set visibility through the PreviousButtonStyle or NextButtonStyle properties, these settings take precedence over the PreviousButtonVisibility or NextButtonVisibility properties, respectively (unless they are set to the PipsPagerButtonVisibility value of Collapsed).



XAML

```
<Page.Resources>
    <Style x:Key="NavButtonBaseStyle" TargetType="Button" BasedOn="
{StaticResource PipsPagerNavigationButtonBaseStyle}">
        <Setter Property="Width" Value="30" />
        <Setter Property="Height" Value="30" />
        <Setter Property="FontSize" Value="12" />
    </Style>

    <Style x:Key="PreviousButtonStyle" BasedOn="{StaticResource
NavButtonBaseStyle}" TargetType="Button">
        <Setter Property="Content" Value="&#xEDDB;" />
    </Style>

    <Style x:Key="NextButtonStyle" BasedOn="{StaticResource
NavButtonBaseStyle}" TargetType="Button">
        <Setter Property="Content" Value="&#xEDDC;" />
    </Style>
</Page.Resources>

<PipsPager x:Name="CustomNavButtonPipsPager"
    PreviousButtonStyle="{StaticResource PreviousButtonStyle}"
    NextButtonStyle="{StaticResource NextButtonStyle}"
    PreviousButtonVisibility="VisibleOnPointerOver"
    NextButtonVisibility="VisibleOnPointerOver" />
```

UWP and WinUI 2

> **Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

The PipsPager for UWP apps requires WinUI 2. For more info, including installation instructions, see WinUI 2. APIs for this control exist in the Microsoft.UI.Xaml.Controls namespace.

- ✓ **WinUI 2 Apis:** PipsPager class
- ✓ Open the WinUI 2 Gallery app and see the PipsPager in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

To use the code in this article with WinUI 2, use an alias in XAML (we use `muxc`) to represent the Windows UI Library APIs that are included in your project. See Get Started with WinUI 2 for more info.

XAML

```
xmlns:muxc="using:Microsoft.UI.Xaml.Controls"

<muxc:PipsPager />
```

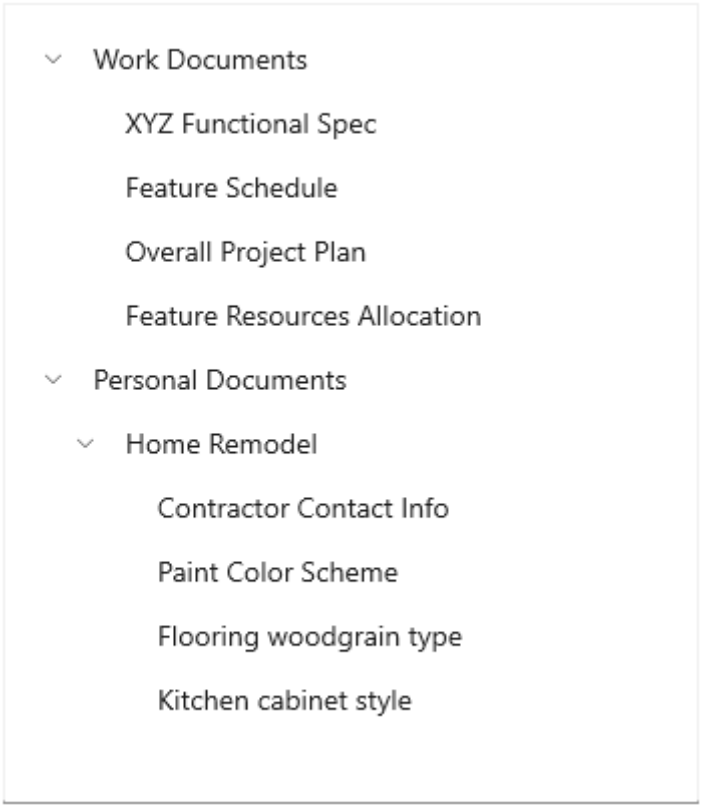
Tree view

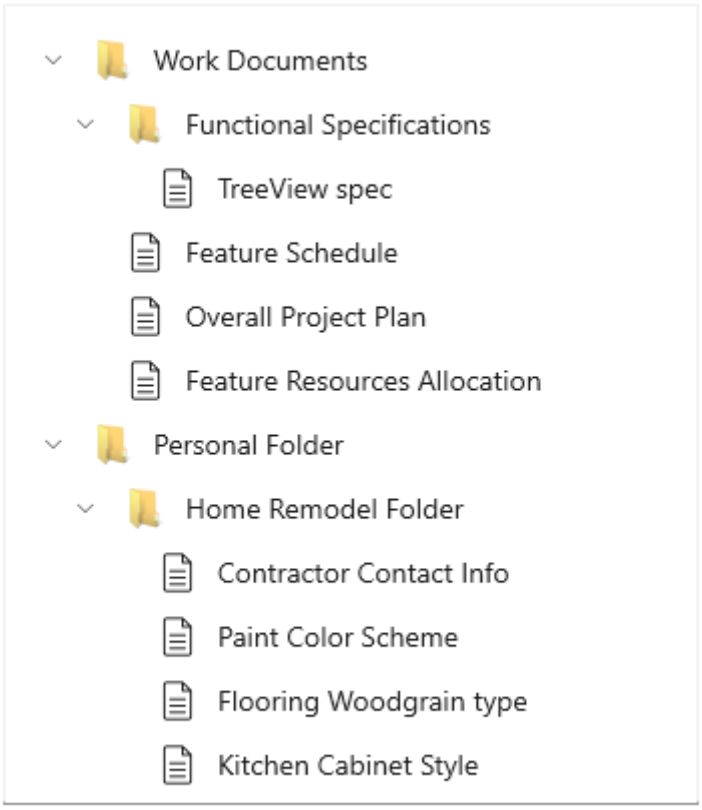
Article • 02/26/2025

The tree view control enables a hierarchical list with expanding and collapsing nodes that contain nested items. It can be used to illustrate a folder structure or nested relationships in your UI.

The tree view uses a combination of indentation and icons to represent the nested relationship between parent nodes and child nodes. Collapsed nodes use a chevron pointing to the right, and expanded nodes use a chevron pointing down.



You can include an icon in the tree view item data template to represent nodes. For example, if you show a file system hierarchy, you could use folder icons for the parent notes and file icons for the leaf nodes.



The **TreeView** APIs support the following features:

- N-level nesting
- Selection of single or multiple nodes
- Data binding to the **ItemsSource** property on **TreeView** and TreeViewItem
- **TreeViewItem** as the root of the **TreeView** item template
- Arbitrary types of content in a **TreeViewItem**
- Drag and drop between tree views

Is this the right control?

- Use a **TreeView** when items have nested list items, and if it is important to illustrate the hierarchical relationship of items to their peers and nodes.
- Avoid using **TreeView** if highlighting the nested relationship of an item is not a priority. For most drill-in scenarios, a regular list view is appropriate.

Create a tree view

You can create a tree view by binding the ItemsSource to a hierarchical data source, or you can create and manage **TreeViewNode** objects yourself.

To create a tree view, you use a TreeView control and a hierarchy of TreeViewNode objects. You create the node hierarchy by adding one or more root nodes to the **TreeView** control's RootNodes collection. Each **TreeViewNode** can then have more nodes added to its Children collection. You can nest tree view nodes to whatever depth you require.

You can bind a hierarchical data source to the ItemsSource property to provide the tree view content, just as you would with ListView's **ItemsSource**. Similarly, use ItemTemplate (and the optional ItemTemplateSelector) to provide a DataTemplate that renders the item.

> **Important**
>
> **ItemsSource** and its related APIs require Windows 10, version 1809 (SDK 17763) or later, or WinUI 2.
>
> **ItemsSource** is an alternative mechanism to **TreeView.RootNodes** for putting content into the **TreeView** control. You cannot set both **ItemsSource** and **RootNodes** at the same time. When you use **ItemsSource**, nodes are created for you, and you can access them from the **TreeView.RootNodes** property.

Here's an example of a simple tree view declared in XAML. You typically add the nodes in code, but we show the XAML hierarchy here because it can be helpful for visualizing how the hierarchy of nodes is created.

XAML

```
<muxc:TreeView>
    <muxc:TreeView.RootNodes>
        <muxc:TreeViewNode Content="Flavors"
                           IsExpanded="True">
            <muxc:TreeViewNode.Children>
                <muxc:TreeViewNode Content="Vanilla"/>
                <muxc:TreeViewNode Content="Strawberry"/>
                <muxc:TreeViewNode Content="Chocolate"/>
            </muxc:TreeViewNode.Children>
        </muxc:TreeViewNode>
    </muxc:TreeView.RootNodes>
</muxc:TreeView>
```

In most cases, your tree view displays data from a data source, so you typically declare the root **TreeView** control in XAML, but add the **TreeViewNode** objects in code or using data binding.

Bind to a hierarchical data source

To create a tree view using data binding, set a hierarchical collection to the **TreeView.ItemsSource** property. Then in the **ItemTemplate**, set the child items collection to the **TreeViewItem.ItemsSource** property.

XAML

```
<muxc:TreeView ItemsSource="{x:Bind DataSource}">
    <muxc:TreeView.ItemTemplate>
        <DataTemplate x:DataType="local:Item">
            <muxc:TreeViewItem ItemsSource="{x:Bind Children}"
                               Content="{x:Bind Name}"/>
        </DataTemplate>
    </muxc:TreeView.ItemTemplate>
</muxc:TreeView>
```

See Tree view using data binding for the full code.

Items and item containers

If you use **TreeView.ItemsSource**, these APIs are available to get the node or data item from the container, and vice versa.

Expand table

TreeViewItem	Description
TreeView.ItemFromContainer	Gets the data item for the specified **TreeViewItem** container.
TreeView.ContainerFromItem	Gets the **TreeViewItem** container for the specified data item.

Expand table

TreeViewNode	Description
TreeView.NodeFromContainer	Gets the **TreeViewNode** for the specified **TreeViewItem** container.
TreeView.ContainerFromNode	Gets the **TreeViewItem** container for the specified **TreeViewNode**.

Manage tree view nodes

This tree view is the same as the one created previously in XAML, but the nodes are created in code instead.

XAML

```
<muxc:TreeView x:Name="sampleTreeView"/>
```

C#

```
private void InitializeTreeView()
{
    muxc.TreeViewNode rootNode = new muxc.TreeViewNode() { Content =
"Flavors" };
    rootNode.IsExpanded = true;
    rootNode.Children.Add(new muxc.TreeViewNode() { Content = "Vanilla" });
    rootNode.Children.Add(new muxc.TreeViewNode() { Content = "Strawberry"
});
    rootNode.Children.Add(new muxc.TreeViewNode() { Content = "Chocolate"
});

    sampleTreeView.RootNodes.Add(rootNode);
}
```

These APIs are available for managing the data hierarchy of your tree view.

Expand table

TreeView	Description
RootNodes	A tree view can have one or more root nodes. Add a **TreeViewNode** object to the **RootNodes** collection to create a root node. The **Parent** of a root node is always **null**. The **Depth** of a root node is 0.

Expand table

TreeViewNode	Description
Children	Add **TreeViewNode** objects to the **Children** collection of a parent node to create your node hierarchy. A node is the **Parent** of all nodes in its **Children** collection.
HasChildren	**true** if the node has realized children. **false** indicates an empty folder or an item.
HasUnrealizedChildren	Use this property if you're filling nodes as they're expanded. See Fill a node when it's expanding later in this article.
Depth	Indicates how far from the root node a child node is.

TreeViewNode	Description
Parent	Gets the **TreeViewNode** that owns the **Children** collection that this node is part of.

The tree view uses the **HasChildren** and **HasUnrealizedChildren** properties to determine whether the expand/collapse icon is shown. If either property is **true**, the icon is shown; otherwise, it's not shown.

Tree view node content

You can store the data item that a tree view node represents in its Content property.

In the previous examples, the content was a simple string value. Here, a tree view node represents the user's **Pictures** folder, so the pictures library StorageFolder is assigned to the node's **Content** property.

C#

```
StorageFolder picturesFolder = KnownFolders.PicturesLibrary;
muxc.TreeViewNode pictureNode = new muxc.TreeViewNode();
pictureNode.Content = picturesFolder;
```

> ⓘ Note
>
> To get access to the **Pictures** folder, you need to specify the **Pictures Library** capability in the app manifest. See App capability declarations for more information.

You can provide a DataTemplate to specify how the data item is displayed in the tree view.

> ⓘ Note
>
> In Windows 10, version 1803, you have to re-template the **TreeView** control and specify a custom **ItemTemplate** if your content is not a string. In later versions, set the **ItemTemplate** property. For more info, see TreeView.ItemTemplate.

Item container style

Whether you use **ItemsSource** or **RootNodes**, the actual element used to display each node – called the "container" – is a TreeViewItem object. You can modify **TreeViewItem** properties to style the container using the **TreeView**'s ItemContainerStyle or ItemContainerStyleSelector properties.

This example shows how to change the expanded/collapsed glyphs to orange +/- signs. In the default **TreeViewItem** template, the glyphs are set to use the `Segoe MDL2 Assets` font. You can set the **Setter.Value** property by providing the Unicode character value in the format used by XAML, like this: `Value=""`.

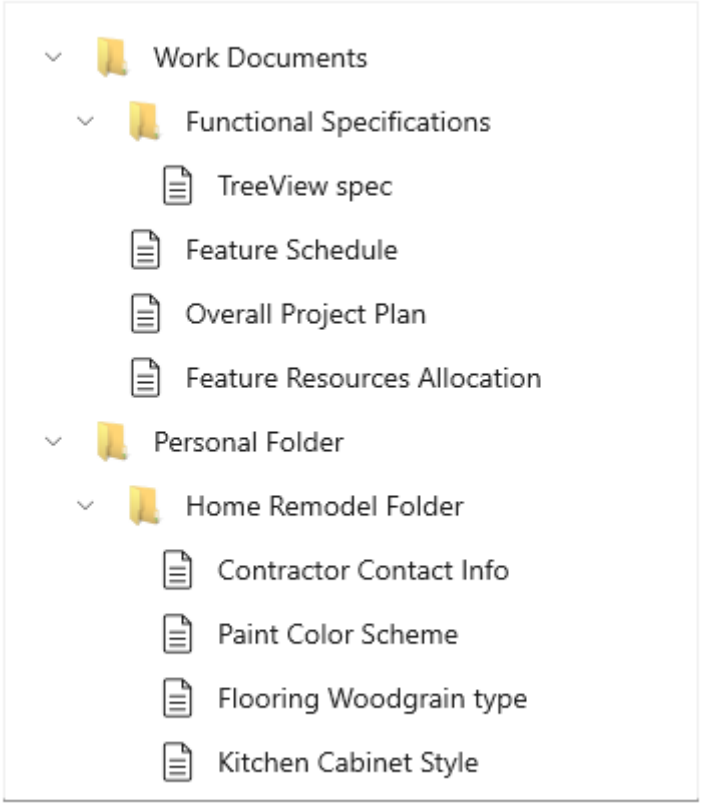
XAML

```
<muxc:TreeView>
    <muxc:TreeView.ItemContainerStyle>
        <Style TargetType="muxc:TreeViewItem">
            <Setter Property="CollapsedGlyph" Value="&#xE948;"/>
            <Setter Property="ExpandedGlyph" Value="&#xE949;"/>
            <Setter Property="GlyphBrush" Value="DarkOrange"/>
        </Style>
    </muxc:TreeView.ItemContainerStyle>
    <muxc:TreeView.RootNodes>
        <muxc:TreeViewNode Content="Flavors"
               IsExpanded="True">
            <muxc:TreeViewNode.Children>
                <muxc:TreeViewNode Content="Vanilla"/>
                <muxc:TreeViewNode Content="Strawberry"/>
                <muxc:TreeViewNode Content="Chocolate"/>
            </muxc:TreeViewNode.Children>
        </muxc:TreeViewNode>
    </muxc:TreeView.RootNodes>
</muxc:TreeView>
```

Item template selectors

By default, the TreeView shows the string representation of the data item for each node. You can set the ItemTemplate property to change what is displayed for all nodes. Or, you can use an ItemTemplateSelector to choose a different DataTemplate for the tree view items based on the type of item or some other criteria you specify.

For example, in a file explorer app, you could use one data template for folders, and another for files.



Here is an example of how to create and use an item template selector. For more info, see the DataTemplateSelector class.

> **Note**
>
> This code is part of a larger example and won't work on its own. To see the full example, including the code that defines `ExplorerItem`, check out the Xaml-Controls-Gallery repository on GitHub. TreeViewPage.xaml and TreeViewPage.xaml.cs contain the relevant code.

XAML

```
<Page.Resources>
    <DataTemplate x:Key="FolderTemplate" x:DataType="local:ExplorerItem">
        <muxc:TreeViewItem ItemsSource="{x:Bind Children}">
            <StackPanel Orientation="Horizontal">
                <Image Width="20" Source="Assets/folder.png"/>
                <TextBlock Text="{x:Bind Name}" />
            </StackPanel>
        </muxc:TreeViewItem>
    </DataTemplate>

    <DataTemplate x:Key="FileTemplate" x:DataType="local:ExplorerItem">
        <muxc:TreeViewItem>
            <StackPanel Orientation="Horizontal">
```

```
                <Image Width="20" Source="Assets/file.png"/>
                <TextBlock Text="{x:Bind Name}"/>
            </StackPanel>
        </muxc:TreeViewItem>
    </DataTemplate>

    <local:ExplorerItemTemplateSelector
            x:Key="ExplorerItemTemplateSelector"
            FolderTemplate="{StaticResource FolderTemplate}"
            FileTemplate="{StaticResource FileTemplate}" />
</Page.Resources>

<Grid>
    <muxc:TreeView
        ItemsSource="{x:Bind DataSource}"
        ItemTemplateSelector="{StaticResource
ExplorerItemTemplateSelector}"/>
</Grid>
```

C#

```
public class ExplorerItemTemplateSelector : DataTemplateSelector
{
    public DataTemplate FolderTemplate { get; set; }
    public DataTemplate FileTemplate { get; set; }

    protected override DataTemplate SelectTemplateCore(object item)
    {
        var explorerItem = (ExplorerItem)item;
        if (explorerItem.Type == ExplorerItem.ExplorerItemType.Folder)
return FolderTemplate;

        return FileTemplate;
    }
}
```

The type of object passed to the SelectTemplateCore method depends on whether you create the tree view by setting the **ItemsSource** property, or by creating and managing **TreeViewNode** objects yourself.

- If **ItemsSource** is set, the object will be of whatever type the data item is. In the previous example, the object was an `ExplorerItem`, so it could be used after a simple cast to `ExplorerItem`: `var explorerItem = (ExplorerItem)item;`.
- If **ItemsSource** is not set and you manage the tree view nodes yourself, the object passed to **SelectTemplateCore** is a **TreeViewNode**. In this case, you can get the data item from the TreeViewNode.Content property.

Here's a data template selector from the Pictures and Music library tree view example shown later. The **SelectTemplateCore** method receives a **TreeViewNode**, which might

have either a StorageFolder or a StorageFile as its content. Based on the content, you can return a default template, or a specific template for the music folder, the picture folder, music files, or picture files.

C#

```
protected override DataTemplate SelectTemplateCore(object item)
{
    var node = (TreeViewNode)item;
    if (node.Content is StorageFolder)
    {
        var content = node.Content as StorageFolder;
        if (content.DisplayName.StartsWith("Pictures")) return
PictureFolderTemplate;
        if (content.DisplayName.StartsWith("Music")) return
MusicFolderTemplate;
    }
    else if (node.Content is StorageFile)
    {
        var content = node.Content as StorageFile;
        if (content.ContentType.StartsWith("image")) return
PictureItemTemplate;
        if (content.ContentType.StartsWith("audio")) return
MusicItemTemplate;
    }
    return DefaultTemplate;
}
```

Interacting with a tree view

You can configure a tree view to let a user interact with it in several different ways:

- Expand or collapse nodes
- Single- or multi-select items
- Click to invoke an item

Expand/collapse

Any tree view node that has children can always be expanded or collapsed by clicking the expand/collapse glyph. You can also expand or collapse a node programmatically, and respond when a node changes state.

Expand/collapse a node programmatically

There are 2 ways you can expand or collapse a tree view node in your code.

- The TreeView class has the Collapse and Expand methods. When you call these methods, you pass in the **TreeViewNode** that you want to expand or collapse.
- Each TreeViewNode has the IsExpanded property. You can use this property to check the state of a node, or set it to change the state. You can also set this property in XAML to set the initial state of a node.

Fill a node when it's expanding

You might need to show a large number of nodes in your tree view, or you might not know ahead of time how many nodes it will have. The **TreeView** control is not virtualized, so you can manage resources by filling each node as it's expanded, and removing the child nodes when it's collapsed.

Handle the Expanding event and use the HasUnrealizedChildren property to add children to a node when it's being expanded. The **HasUnrealizedChildren** property indicates whether the node needs to be filled, or if its **Children** collection has already been populated. It's important to remember that the **TreeViewNode** doesn't set this value, you need to manage it in your app code.

Here's an example of these APIs in use. See the complete example code at the end of this article for context, including the implementation of **FillTreeNode**.

C#

```
private void SampleTreeView_Expanding(muxc.TreeView sender,
muxc.TreeViewExpandingEventArgs args)
{
    if (args.Node.HasUnrealizedChildren)
    {
        FillTreeNode(args.Node);
    }
}
```

It's not required, but you might want to also handle the Collapsed event and remove the child nodes when the parent node is closed. This can be important if your tree view has many nodes, or if the node data uses a lot of resources. You should consider the performance impact of filling a node each time it's opened versus leaving the children on a closed node. The best option will depend on your app.

Here's an example of a handler for the **Collapsed** event.

C#

```
private void SampleTreeView_Collapsed(muxc.TreeView sender,
muxc.TreeViewCollapsedEventArgs args)
{
    args.Node.Children.Clear();
    args.Node.HasUnrealizedChildren = true;
}
```

Invoking an item

A user can invoke an action (treating the item like a button) instead of selecting the item. You handle the ItemInvoked event to respond to this user interaction.

> ⓘ **Note**
>
> Unlike **ListView**, which has the IsItemClickEnabled property, invoking an item is always enabled on the tree view. You can still choose whether to handle the event or not.

TreeViewItemInvokedEventArgs class

The **ItemInvoked** event args give you access to the invoked item. The InvokedItem property has the node that was invoked. You can cast it to a **TreeViewNode** and get the data item from the **TreeViewNode.Content** property.

Here's an example of an **ItemInvoked** event handler. The data item is an IStorageItem, and this example just displays some info about the file and tree. Also, if the node is a folder node, it expands or collapses the node at the same time. Otherwise, the node expands or collapses only when the chevron is clicked.

C#

```
private void SampleTreeView_ItemInvoked(muxc.TreeView sender,
muxc.TreeViewItemInvokedEventArgs args)
{
    var node = args.InvokedItem as muxc.TreeViewNode;
    if (node.Content is IStorageItem item)
    {
        FileNameTextBlock.Text = item.Name;
        FilePathTextBlock.Text = item.Path;
        TreeDepthTextBlock.Text = node.Depth.ToString();

        if (node.Content is StorageFolder)
        {
            node.IsExpanded = !node.IsExpanded;
        }
```

```
    }
}
```

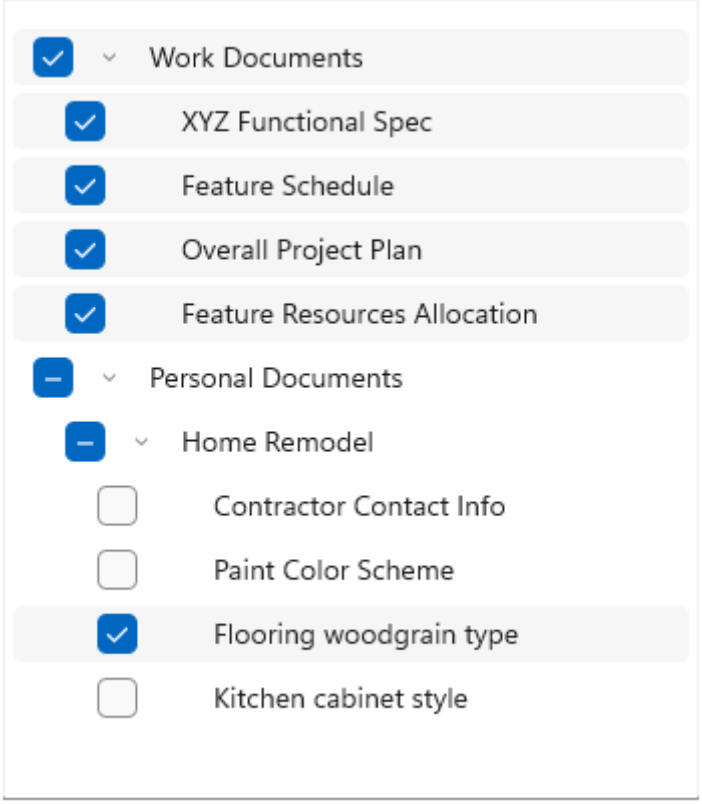
Item selection

The **TreeView** control supports both single-selection and multi-selection. By default, selection of nodes is turned off, but you can set the TreeView.SelectionMode property to allow selection of nodes. The TreeViewSelectionMode values are **None**, **Single**, and **Multiple**.

Multiple selection

When multiple selection is enabled, a checkbox is shown next to each tree view node, and selected items are highlighted. A user can select or de-select an item by using the checkbox; clicking the item still causes it to be invoked.

Selecting or de-selecting a parent node will select or de-select all children under that node. If some, but not all, of the children under a parent node are selected, the checkbox for the parent node is shown in the indeterminate state.



Selected nodes are added to the tree view's SelectedNodes collection. You can call the SelectAll method to select all the nodes in a tree view.

> **Note**
>
> If you call **SelectAll**, all realized nodes are selected, regardless of the **SelectionMode**. To provide a consistent user experience, you should only call **SelectAll** if **SelectionMode** is **Multiple**.

Selection and realized/unrealized nodes

If your tree view has unrealized nodes, they are not taken into account for selection. Here are some things you need to keep in mind regarding selection with unrealized nodes.

- If a user selects a parent node, all the realized children under that parent are also selected. Similarly, if all the child nodes are selected, the parent node also becomes selected.
- The **SelectAll** method only adds realized nodes to the **SelectedNodes** collection.
- If a parent node with unrealized children is selected, the children will be selected as they are realized.

SelectedItem/SelectedItems

TreeView has the SelectedItem and SelectedItems properties. You can use these properties to get the content of selected nodes directly. If multiple selection is enabled, SelectedItem contains the first item in the SelectedItems collection.

SelectionChanged

You can handle the SelectionChanged event to respond when the collection of selected items changes, either programmatically or through user interaction.

XAML

```
<TreeView ItemsSource="{x:Bind Folders}"
          SelectionMode="Multiple"
          SelectionChanged="TreeView_SelectionChanged"/>
```

C#

```
public void TreeView_SelectionChanged(TreeView sender,
TreeViewSelectionChangedEventArgs args)
{
    foreach (object item in args.RemovedItems)
```

```
    {
        this.SelectedFolders.Remove((Folder)item);
    }

    foreach (object item in args.AddedItems)
    {
        this.SelectedFolders.Add((Folder)item);
    }
}
```

Code examples

The following code examples demonstrate various features of the tree view control.

Tree view using XAML

This example shows how to create a simple tree view structure in XAML. The tree view shows ice cream flavors and toppings that the user can choose from, arranged in categories. Multi-selection is enabled, and when the user clicks a button, the selected items are displayed in the main app UI.

XAML

```
<Page
    x:Class="TreeViewTest.MainPage"
    xmlns="http://schemas.microsoft.com/winfx/2006/xaml/presentation"
    xmlns:x="http://schemas.microsoft.com/winfx/2006/xaml"
    xmlns:d="http://schemas.microsoft.com/expression/blend/2008"
    xmlns:mc="http://schemas.openxmlformats.org/markup-compatibility/2006"
    xmlns:muxc="using:Microsoft.UI.Xaml.Controls"
    mc:Ignorable="d"
    Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">

    <Grid Background="{ThemeResource ApplicationPageBackgroundThemeBrush}"
          Padding="100">
        <SplitView IsPaneOpen="True"
               DisplayMode="Inline"
               OpenPaneLength="296">
            <SplitView.Pane>
                <muxc:TreeView x:Name="DessertTree"
SelectionMode="Multiple">
                    <muxc:TreeView.RootNodes>
                        <muxc:TreeViewNode Content="Flavors"
IsExpanded="True">
                            <muxc:TreeViewNode.Children>
                                <muxc:TreeViewNode Content="Vanilla"/>
                                <muxc:TreeViewNode Content="Strawberry"/>
                                <muxc:TreeViewNode Content="Chocolate"/>
                            </muxc:TreeViewNode.Children>
```

```
                        </muxc:TreeViewNode>

                        <muxc:TreeViewNode Content="Toppings">
                            <muxc:TreeViewNode.Children>
                                <muxc:TreeViewNode Content="Candy">
                                    <muxc:TreeViewNode.Children>
                                        <muxc:TreeViewNode
Content="Chocolate"/>
                                        <muxc:TreeViewNode Content="Mint"/>
                                        <muxc:TreeViewNode
Content="Sprinkles"/>
                                    </muxc:TreeViewNode.Children>
                                </muxc:TreeViewNode>

                <TextBlock x:Name="ToppingList"/>
            </StackPanel>
        </SplitView>
    </Grid>
</Page>
```

C#

```
using Windows.UI.Xaml;
using Windows.UI.Xaml.Controls;
using muxc = Microsoft.UI.Xaml.Controls;

namespace TreeViewTest
{
    public sealed partial class MainPage : Page
    {
        public MainPage()
        {
            this.InitializeComponent();
        }

        private void OrderButton_Click(object sender, RoutedEventArgs e)
        {
            FlavorList.Text = string.Empty;
            ToppingList.Text = string.Empty;

            foreach (muxc.TreeViewNode node in DessertTree.SelectedNodes)
            {
                if (node.Parent.Content?.ToString() == "Flavors")
                {
                    FlavorList.Text += node.Content + "; ";
                }
                else if (node.HasChildren == false)
                {
                    ToppingList.Text += node.Content + "; ";
                }
            }
        }

        private void SelectAllButton_Click(object sender, RoutedEventArgs e)
        {
            if (DessertTree.SelectionMode ==
muxc.TreeViewSelectionMode.Multiple)
            {
                DessertTree.SelectAll();
            }
        }
    }
}
```

Tree view using data binding

This example shows how to create the same tree view as the previous example. However, instead of creating the data hierarchy in XAML, the data is created in code and bound to the tree view's **ItemsSource** property. (The button event handlers shown in the previous example apply to this example also.)

XAML

```
<Page
    x:Class="TreeViewTest.MainPage"
    xmlns="http://schemas.microsoft.com/winfx/2006/xaml/presentation"
    xmlns:x="http://schemas.microsoft.com/winfx/2006/xaml"
    xmlns:d="http://schemas.microsoft.com/expression/blend/2008"
    xmlns:mc="http://schemas.openxmlformats.org/markup-compatibility/2006"
    xmlns:muxc="using:Microsoft.UI.Xaml.Controls"
    xmlns:local="using:TreeViewTest"
    mc:Ignorable="d"
    Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">

    <Grid Background="{ThemeResource ApplicationPageBackgroundThemeBrush}"
          Padding="100">
        <SplitView IsPaneOpen="True"
                   DisplayMode="Inline"
                   OpenPaneLength="296">
            <SplitView.Pane>
                <muxc:TreeView Name="DessertTree"
                                SelectionMode="Multiple"
                                ItemsSource="{x:Bind DataSource}">
                    <muxc:TreeView.ItemTemplate>
                        <DataTemplate x:DataType="local:Item">
                            <muxc:TreeViewItem
                                ItemsSource="{x:Bind Children}"
                                Content="{x:Bind Name}"/>
                        </DataTemplate>
                    </muxc:TreeView.ItemTemplate>
                </muxc:TreeView>
            </SplitView.Pane>

            <StackPanel Grid.Column="1" Margin="12,0">
                <Button Content="Select all"
                        Click="SelectAllButton_Click"/>
                <Button Content="Create order"
                        Click="OrderButton_Click"
                        Margin="0,12"/>
                <TextBlock Text="Your flavor selections:"
                           Style="{StaticResource CaptionTextBlockStyle}"/>
                <TextBlock x:Name="FlavorList" Margin="0,0,0,12"/>
                <TextBlock Text="Your topping selections:"
                           Style="{StaticResource CaptionTextBlockStyle}"/>
                <TextBlock x:Name="ToppingList"/>
            </StackPanel>
        </SplitView>
    </Grid>

</Page>
```

C#

```
using System.Collections.ObjectModel;
using Windows.UI.Xaml;
```

```
using Windows.UI.Xaml.Controls;
using muxc = Microsoft.UI.Xaml.Controls;

namespace TreeViewTest
{

            ToppingList.Text = string.Empty;

            foreach (muxc.TreeViewNode node in DessertTree.SelectedNodes)
            {
                if (node.Parent.Content?.ToString() == "Flavors")
                {
                    FlavorList.Text += node.Content + "; ";
                }
                else if (node.HasChildren == false)
                {
                    ToppingList.Text += node.Content + "; ";
                }
            }
        }

        private void SelectAllButton_Click(object sender, RoutedEventArgs e)
        {
            if (DessertTree.SelectionMode ==
muxc.TreeViewSelectionMode.Multiple)
            {
                DessertTree.SelectAll();
            }
        }
    }

    public class Item
    {
        public string Name { get; set; }
        public ObservableCollection<Item> Children { get; set; } = new
ObservableCollection<Item>();

        public override string ToString()
        {
```

```
            return Name;
        }
    }
}
```

Pictures and Music library tree view

This example shows how to create a tree view that shows the contents and structure of the user's **Pictures** and **Music** libraries. The number of items can't be known ahead of time, so each node is filled when it's expanded, and emptied when it's collapsed.

A custom item template is used to display the data items, which are of type IStorageItem.

> **ⓘ Important**
>
> The code in this example requires the **picturesLibrary** and **musicLibrary** capabilities. For more info about file access, see File access permissions, Enumerate and query files and folders, and Files and folders in the Music, Pictures, and Videos libraries.

XAML

```

Drag and drop items between tree views

The following example demonstrates how to create two tree views whose items can be dragged and dropped between each other. When an item is dragged to the other tree view, it is added to the end of the list. However, items can be re-ordered within a tree view. This example also only takes into account tree views with one root node.

XAML

```
<Page
    x:Class="TreeViewTest.MainPage"

UWP and WinUI 2

> **ⓘ Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

The TreeView for UWP apps is included as part of WinUI 2. For more info, including installation instructions, see WinUI 2. APIs for this control exist in both the Windows.UI.Xaml.Controls (UWP) and Microsoft.UI.Xaml.Controls (WinUI) namespaces.

- ✓ **UWP APIs:** TreeView class, TreeViewNode class, TreeView.ItemsSource property
- ✓ **WinUI 2 Apis:** TreeView class, TreeViewNode class, TreeView.ItemsSource property
- ✓ Open the WinUI 2 Gallery app and see the TreeView in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles, templates, and features for all controls.

To use the code in this article with WinUI 2, use an alias in XAML (we use `muxc`) to represent the Windows UI Library APIs that are included in your project. See Get Started with WinUI 2 for more info.

XAML

```
xmlns:muxc="using:Microsoft.UI.Xaml.Controls"

<muxc:TreeView>
    <muxc:TreeView.RootNodes>
        <muxc:TreeViewNode Content="Flavors">
            <muxc:TreeViewNode.Children>
                <muxc:TreeViewNode Content="Vanilla"/>
            </muxc:TreeViewNode.Children>
        </muxc:TreeViewNode>
    </muxc:TreeView.RootNodes>
</muxc:TreeView>
```

ItemsRepeater

Article • 02/26/2025

Use an ItemsRepeater to create custom collection experiences using a flexible layout system, custom views, and virtualization.

Unlike ListView, ItemsRepeater does not provide a comprehensive end-user experience – it has no default UI and provides no policy around focus, selection, or user interaction. Instead, it's a building block that you can use to create your own unique collection-based experiences and custom controls. While it has no built-in policy, it enables you to attach policy to build the experience you require. For example, you can define the layout to use, the keyboarding policy, the selection policy, etc.

You can think of ItemsRepeater conceptually as a data-driven panel, rather than as a complete control like ListView. You specify a collection of data items to be displayed, an item template that generates a UI element for each data item, and a layout that determines how the elements are sized and positioned. Then, ItemsRepeater produces child elements based on the data source, and displays them as specified by the item template and layout. The items displayed do not need to be homogenous because ItemsRepeater can load content to represent the data items based on criteria you specify in a data template selector.

Is this the right control?

Use an ItemsRepeater to create custom displays for collections of data. While it can be used to present a basic set of items, you might often use it as the display element in the template of a custom control.

If you need an out-of-the-box control to display data in a list or grid with minimal customization, consider using a ListView or GridView.

ItemsRepeater does not have a built-in Items collection. If you need to provide an Items collection directly, rather than binding to a separate data source, then you're likely in need of a more high-policy experience and should use ListView or GridView.

ItemsControl and ItemsRepeater both enable customizable collection experiences, but ItemsRepeater supports virtualizing UI layouts, while ItemsControl does not. We recommend using ItemsRepeater instead of ItemsControl, whether its for just presenting a few items from data or building a custom collection control.

Scrolling with ItemsRepeater

ItemsRepeater does not derive from Control, so it doesn't have a control template. Therefore, it doesn't contain any built-in scrolling like a ListView or other collection controls do.

When you use an **ItemsRepeater**, you should provide scrolling functionality by wrapping it in a ScrollViewer control.

> **Note**
>
> If your app will run on earlier versions of Windows - those released *before* Windows 10, version 1809 - then you also need to host the **ScrollViewer** inside the ItemsRepeaterScrollHost.
>
> XAML
>
> ```
> <muxc:ItemsRepeaterScrollHost>
>     <ScrollViewer>
>         <muxc:ItemsRepeater ... />
>     </ScrollViewer>
> </muxc:ItemsRepeaterScrollHost>
> ```
>
> If your app will only run on recent versions of Windows 10, version 1809 and later - then there is no need to use the ItemsRepeaterScrollHost.
>
> Prior to Windows 10, version 1809, **ScrollViewer** did not implement the IScrollAnchorProvider interface that the **ItemsRepeater** needs. The **ItemsRepeaterScrollHost** enables the **ItemsRepeater** to coordinate with **ScrollViewer** on earlier releases to correctly preserve the visible location of items the user is viewing. Otherwise, the items might appear to move or disappear suddenly when the items in the list are changed or the app is resized.

Create an ItemsRepeater

✓ **Important APIs**: ItemsRepeater class, ScrollViewer class

Open the WinUI 3 Gallery app and see the ItemsRepeater in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

To use an ItemsRepeater, you need to give it the data to display by setting the **ItemsSource** property. Then, tell it how to display the items by setting the ItemTemplate property.

ItemsSource

To populate the view, set the ItemsSource property to a collection of data items. Here, the **ItemsSource** is set in code directly to an instance of a collection.

C#

```
ObservableCollection<string> Items = new ObservableCollection<string>();

ItemsRepeater itemsRepeater1 = new ItemsRepeater();
itemsRepeater1.ItemsSource = Items;
```

You can also bind the **ItemsSource** property to a collection in XAML. For more info about data binding, see Data binding overview.

XAML

```
<ItemsRepeater ItemsSource="{x:Bind Items}"/>
```

ItemTemplate

To specify how a data item is visualized, set the ItemTemplate property to a DataTemplate or DataTemplateSelector you have defined. The data template defines how the data is visualized. By default, the item is displayed in the view with a **TextBlock** the uses the string representation of the data object.

However, you typically want to show a more rich presentation of your data by using a template that defines the layout and appearance of one or more controls that you'll use to display an individual item. The controls you use in the template can be bound to the properties of the data object, or have static content defined inline.

DataTemplate

In this example, the data object is a simple string. The **DataTemplate** includes an image to the left of the text, and styles the **TextBlock** to display the string in a teal color.

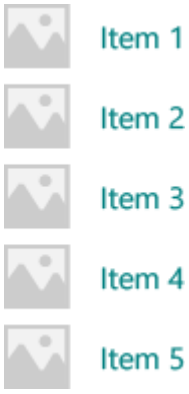
> ⓘ Note

When you use the x:Bind markup extension in a **DataTemplate**, you have to specify the DataType (`x:DataType`) on the DataTemplate.

XAML

```
<DataTemplate x:DataType="x:String">
    <Grid>
        <Grid.ColumnDefinitions>
            <ColumnDefinition Width="47"/>
            <ColumnDefinition/>
        </Grid.ColumnDefinitions>
        <Image Source="Assets/placeholder.png" Width="32" Height="32"
               HorizontalAlignment="Left"/>
        <TextBlock Text="{x:Bind}" Foreground="Teal"
                   FontSize="15" Grid.Column="1"/>
    </Grid>
</DataTemplate>
```

Here's how the items would appear when displayed with this **DataTemplate**.



The number of elements used in the **DataTemplate** for an item can have a significant impact on performance if your view displays a large number of items. For more info and examples of how to use **DataTemplate**s to define the look of items in your list, see Item containers and templates.

Tip

For convenience when you want to declare the template inline rather than referenced as a static resource, you can specify the **DataTemplate** or **DataTemplateSelector** as the direct child of the **ItemsRepeater**. It will be assigned as the value of the **ItemTemplate** property. For example, this is valid:

XAML

```
<ItemsRepeater ItemsSource="{x:Bind Items}">
    <DataTemplate>
```

```
        <!-- ... -->
    </DataTemplate>
</ItemsRepeater>
```

> **Tip**
>
> Unlike **ListView** and other collection controls, the **ItemsRepeater** doesn't wrap the elements from a **DataTemplate** with an additional item container that includes default policy such as margins, padding, selection visuals, or a pointer over visual state. Instead, **ItemsRepeater** only presents what is defined in the **DataTemplate**. If you want your items to have the same look as a list view item, you can explicitly include a container, like **ListViewItem**, in your data template. **ItemsRepeater** will show the **ListViewItem** visuals, but doesn't automatically make use of other functionality, like selection or showing the multi-select checkbox.
>
> Similarly, if your data collection is a collection of actual controls, like **Button** (`List<Button>`), you can put a **ContentPresenter** in your **DataTemplate** to display the control.

DataTemplateSelector

The items you display in your view do not need to be of the same type. You can provide the ItemTemplate property with a DataTemplateSelector to select different **DataTemplate**s based on criteria you specify.

This example assumes a **DataTemplateSelector** has been defined that decides between two different **DataTemplate**s to represent a Large and Small item.

XAML

```
<ItemsRepeater ...>
    <ItemsRepeater.ItemTemplate>
        <local:VariableSizeTemplateSelector Large="{StaticResource
LargeItemTemplate}"
                                            Small="{StaticResource
SmallItemTemplate}"/>
    </ItemsRepeater.ItemTemplate>
</ItemsRepeater>
```

When defining a **DataTemplateSelector** to use with **ItemsRepeater** you only need to implement an override for the SelectTemplateCore(Object) method. For more info and examples, see DataTemplateSelector.

> **Note**
>
> An alternative to **DataTemplate**s to manage how elements are created in more advanced scenarios is to implement your own **IElementFactory** to use as the **ItemTemplate**. It will be responsible for generating content when requested.

Configure the data source

Use the ItemsSource property to specify the collection to use to generate the content of items. You can set the ItemsSource to any type that implements **IEnumerable**. Additional collection interfaces implemented by your data source determine what functionality is available to the ItemsRepeater to interact with your data.

This list shows available interfaces and when to consider using each one.

- IEnumerable(.NET) / IIterable
  - Can be used for small, static data sets.

    At a minimum, the data source must implement the IEnumerable / IIterable interface. If this is all that's supported then the control will iterate through everything once to create a copy that it can use to access items via an index value.
- IReadonlyList(.NET) / IVectorView
  - Can be used for static, read-only data sets.

    Enables the control to access items by index and avoids the redundant internal copy.
- IList(.NET) / IVector
  - Can be used for static data sets.

    Enables the control to access items by index and avoids the redundant internal copy.

    Warning: Changes to the list/vector without implementing INotifyCollectionChanged won't be reflected in the UI.
- INotifyCollectionChanged(.NET)
  - Recommended to support change notification.

Enables the control to observe and react to changes in the data source and reflect those changes in the UI.

- IObservableVector
  - Supports change notification

    Like the **INotifyCollectionChanged** interface, this enables the control to observe and react to changes in the data source.

    Warning: The Windows.Foundation.IObservableVector<T> doesn't support a 'Move' action. This can cause the UI for an item to lose its visual state. For example, an item that is currently selected and/or has focus where the move is achieved by a 'Remove' followed by an 'Add' will lose focus and no longer be selected.

    The Platform.Collections.Vector<T> uses IObservableVector<T> and has this same limitation. If support for a 'Move' action is required then use the **INotifyCollectionChanged** interface. The .NET ObservableCollection<T> class uses **INotifyCollectionChanged**.

- IKeyIndexMapping
  - When a unique identifier can be associated with each item. Recommended when using 'Reset' as the collection change action.

    Enables the control to very efficiently recover the existing UI after receiving a hard 'Reset' action as part of an **INotifyCollectionChanged** or **IObservableVector** event. After receiving a reset the control will use the provided unique ID to associate the current data with elements it had already created. Without the key to index mapping the control would have to assume it needs to start over from scratch in creating UI for the data.

The interfaces listed above, other than IKeyIndexMapping, provide the same behavior in ItemsRepeater as they do in ListView and GridView.

The following interfaces on an ItemsSource enable special functionality in the ListView and GridView controls, but currently have no effect on an ItemsRepeater:

- ISupportIncrementalLoading
- IItemsRangeInfo
- ISelectionInfo

> **Tip**

We want your feedback! Let us know what you think on the **WinUI GitHub project**. Consider adding your thoughts on existing proposals such as **#374**: Add incremental loading support for ItemsRepeater.

An alternative approach to incrementally load your data as the user scrolls up or down is to observe the position of the ScrollViewer's viewport and load more data as the viewport approaches the extent.

XAML

```
<ScrollViewer ViewChanged="ScrollViewer_ViewChanged">
    <ItemsRepeater ItemsSource="{x:Bind MyItemsSource}" .../>
</ScrollViewer>
```

C#

```
private async void ScrollViewer_ViewChanged(object sender,
ScrollViewerViewChangedEventArgs e)
{
    if (!e.IsIntermediate)
    {
        var scroller = (ScrollViewer)sender;
        var distanceToEnd = scroller.ExtentHeight - (scroller.VerticalOffset
+ scroller.ViewportHeight);

        // trigger if within 2 viewports of the end
        if (distanceToEnd <= 2.0 * scroller.ViewportHeight
                && MyItemsSource.HasMore && !itemsSource.Busy)
        {
            // show an indeterminate progress UI
            myLoadingIndicator.Visibility = Visibility.Visible;

            await MyItemsSource.LoadMoreItemsAsync(/*DataFetchSize*/);

            loadingIndicator.Visibility = Visibility.Collapsed;
        }
    }
}
```

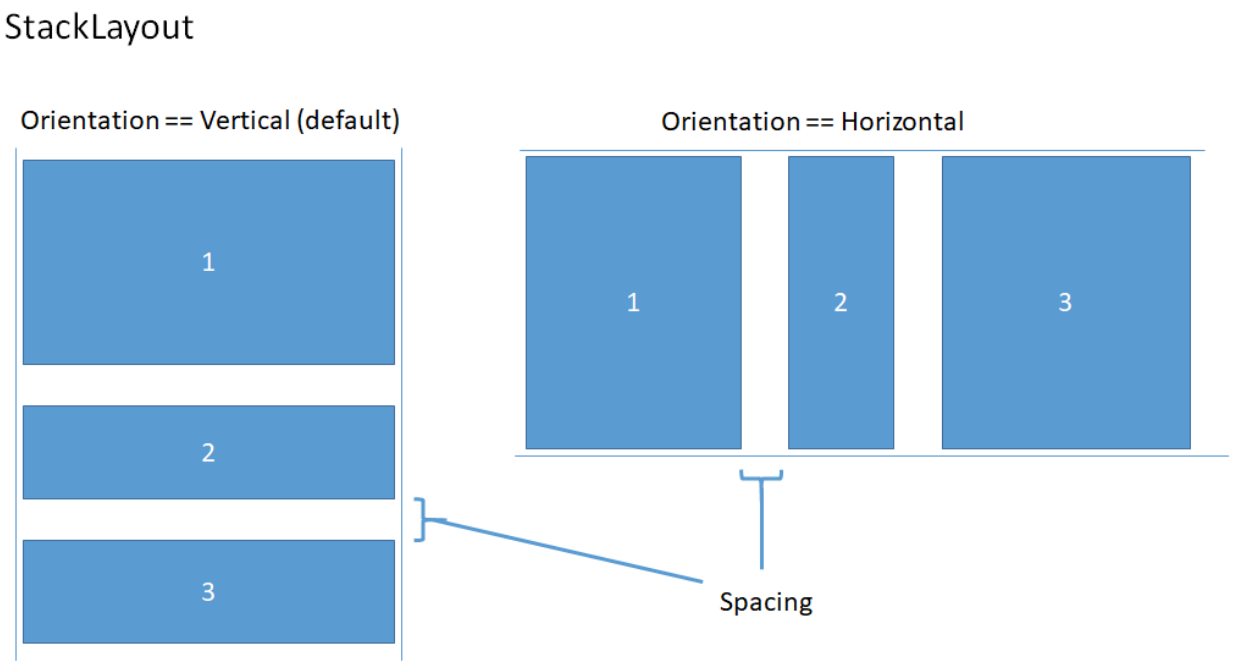
Change the layout of items

Items shown by the ItemsRepeater are arranged by a Layout object that manages the sizing and positioning of its child elements. When used with an ItemsRepeater, the Layout object enables UI virtualization. The layouts provided are StackLayout and UniformGridLayout. By default, ItemsRepeater uses a StackLayout with vertical orientation.

StackLayout

StackLayout arranges elements into a single line that you can orient horizontally or vertically.

You can set the Spacing property to adjust the amount of space between items. Spacing is applied in the direction of the layout's Orientation.



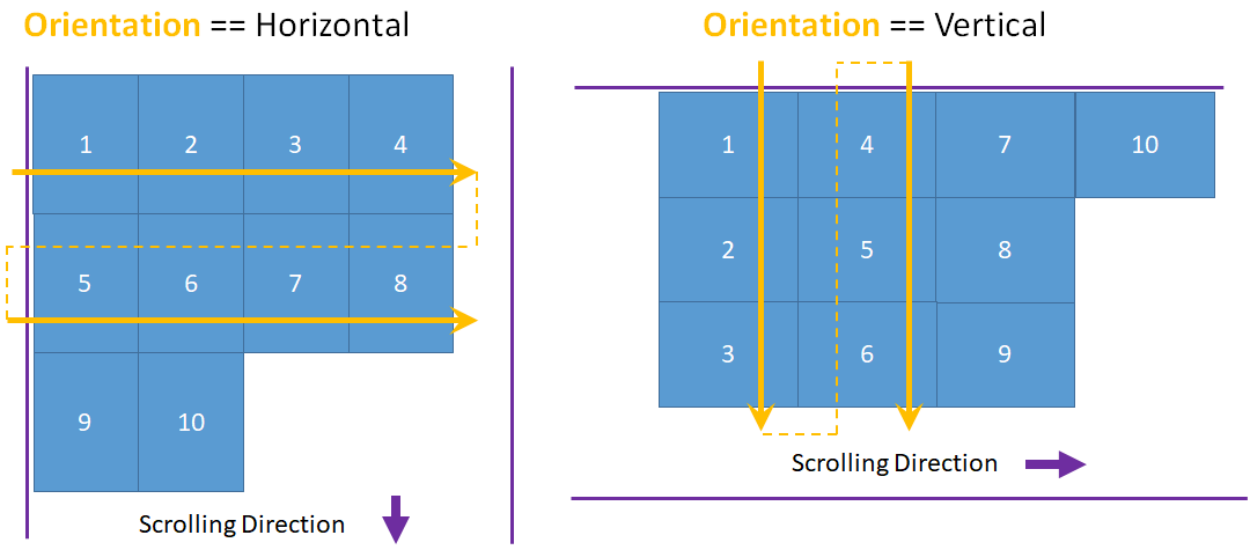
This example shows how to set the ItemsRepeater.Layout property to a StackLayout with horizontal orientation and spacing of 8 pixels.

XAML

```
<!-- xmlns:muxc="using:Microsoft.UI.Xaml.Controls" -->
<muxc:ItemsRepeater ItemsSource="{x:Bind Items}" ItemTemplate="
{StaticResource MyTemplate}">
    <muxc:ItemsRepeater.Layout>
        <muxc:StackLayout Orientation="Horizontal" Spacing="8"/>
    </muxc:ItemsRepeater.Layout>
</muxc:ItemsRepeater>
```

UniformGridLayout

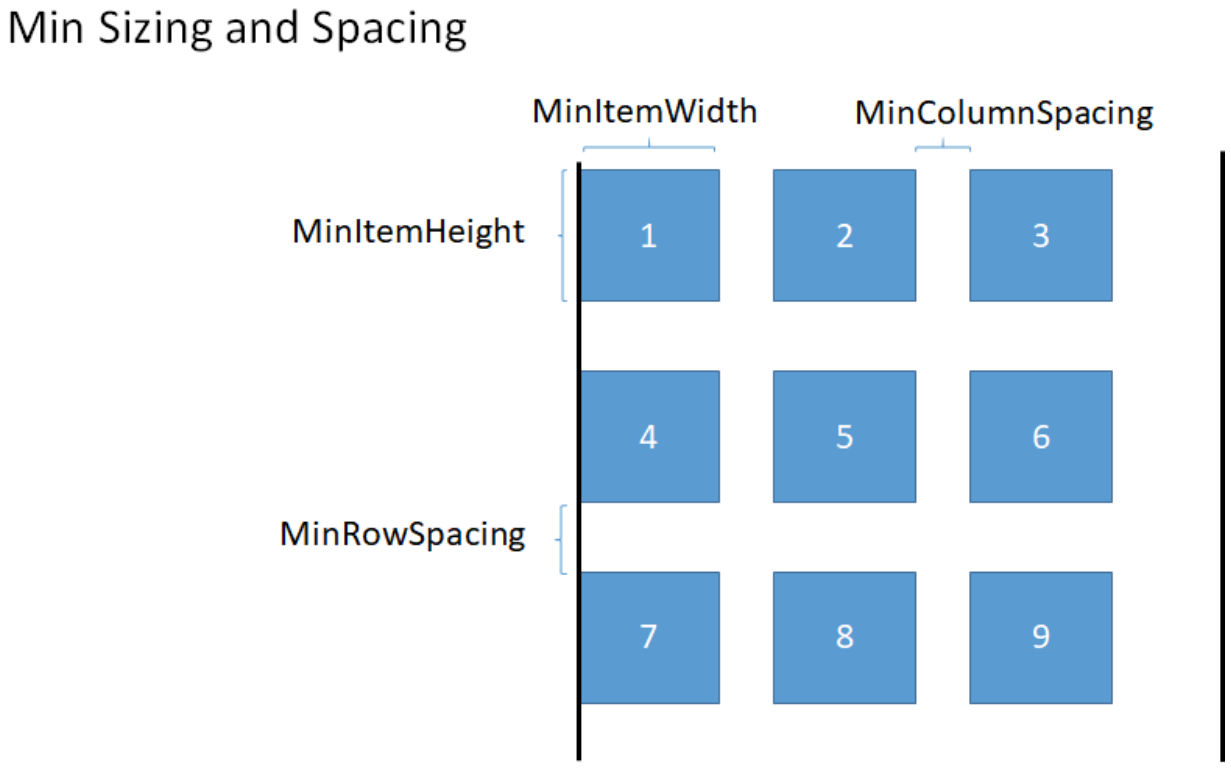
The UniformGridLayout positions elements sequentially in a wrapping layout. Items are layed out in order from left-to-right when the Orientation is **Horizontal**, and layed out top-to-bottom when the Orientation is **Vertical**. Every item is sized equally.



The number of items in each row of a horizontal layout is influenced by the minimum item width. The number of items in each column of a vertical layout is influenced by the minimum item height.

- You can explicitly provide a minimum size to use by setting the MinItemHeight and MinItemWidth properties.
- If you don't specify a minimum size, the measured size of the first item is considered the minimum size per item.

You can also set minimum spacing for the layout to include between rows and columns by setting the MinColumnSpacing and MinRowSpacing properties.



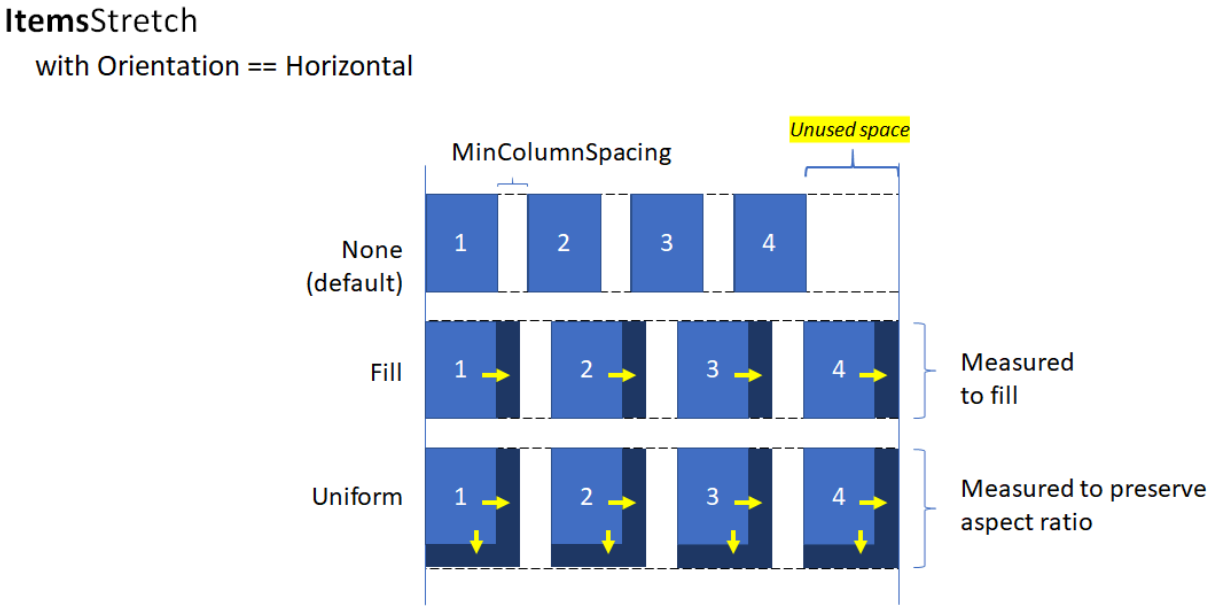
After the number of items in a row or column has been determined based on the item's minimum size and spacing, there might be unused space left after the last item in the row or column (as illustrated in the previous image). You can specify whether any extra space is ignored, used to increase the size of each item, or used to create extra space between the items. This is controlled by the ItemsStretch and ItemsJustification properties.

You can set the ItemsStretch property to specify how the item size is increased to fill the unused space.

This list shows the available values. The definitions assume the default **Orientation** of **Horizontal**.

- **None**: Extra space is left unused at the end of the row. This is the default.
- **Fill**: The items are given extra width to use up the available space (height if vertical).
- **Uniform**: The items are given extra width to use up the available space, and given extra height in order to maintain aspect ratio (height and width are switched if vertical).

This image shows the effect of the **ItemsStretch** values in a horizontal layout.



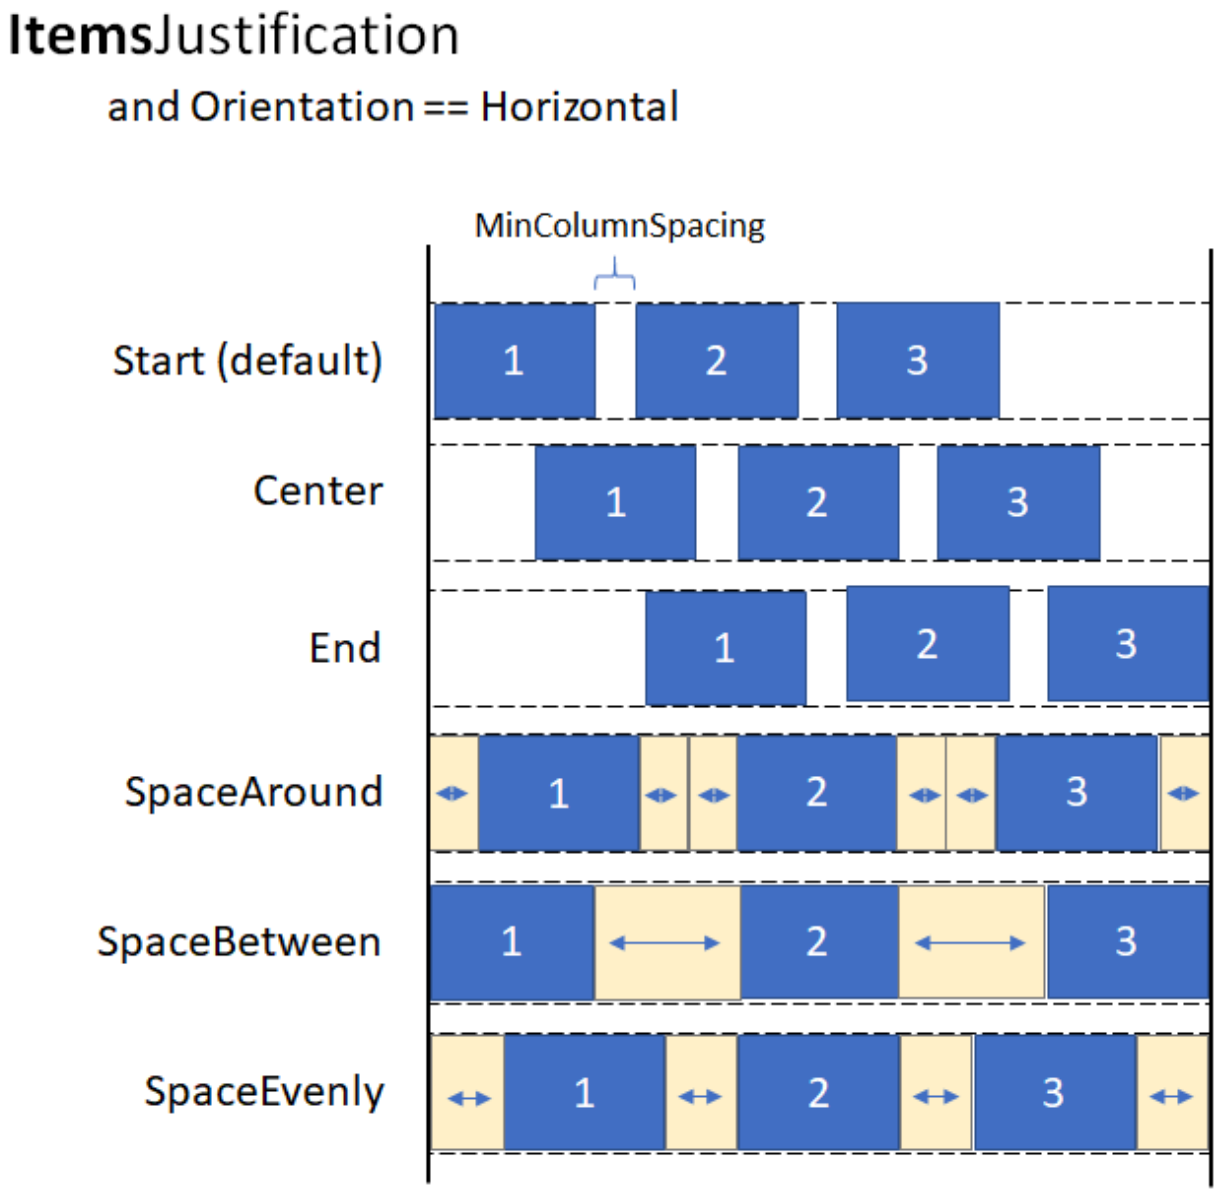
When **ItemsStretch** is **None**, you can set the ItemsJustification property to specify how extra space is used to align the items.

This list shows the available values. The definitions assume the default **Orientation** of **Horizontal**.

- **Start**: Items are aligned with the start of the row. Extra space is left unused at the end of the row. This is the default.

- **Center**: Items are aligned in the center of the row. Extra space is divided evenly at the start and end of the row.
- **End**: Items are aligned with the end of the row. Extra space is left unused at the start of the row.
- **SpaceAround**: Items are distributed evenly. An equal amount of space is added before and after each item.
- **SpaceBetween**: Items are distributed evenly. An equal amount of space is added between each item. No space is added at the start and end of the row.
- **SpaceEvenly**: Items are distributed evenly with an equal amount of space both between each item and at the start and end of the row.

This image shows the effect of the **ItemsStretch** values in a vertical layout (applied to columns instead of rows).



Tip

The **ItemsStretch** property affects the *measure* pass of layout. The **ItemsJustification** property affects the *arrange* pass of layout.

This example shows how to set the **ItemsRepeater.Layout** property to a **UniformGridLayout**.

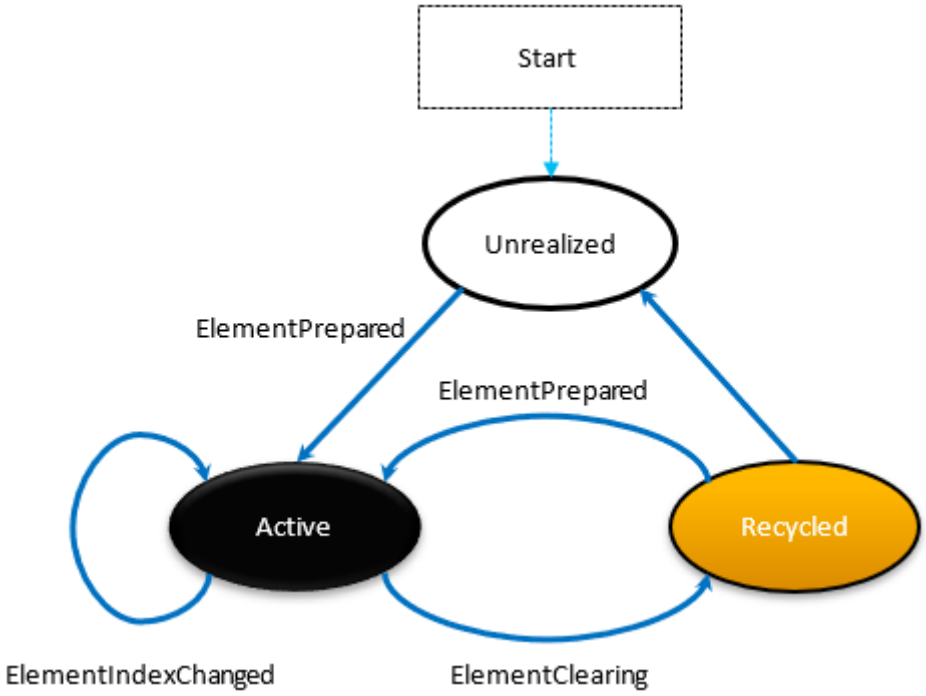
XAML

```
<!-- xmlns:muxc="using:Microsoft.UI.Xaml.Controls" -->
<muxc:ItemsRepeater ItemsSource="{x:Bind Items}"
                    ItemTemplate="{StaticResource MyTemplate}">
    <muxc:ItemsRepeater.Layout>
        <muxc:UniformGridLayout MinItemWidth="200"
                                MinColumnSpacing="28"
                                ItemsJustification="SpaceAround"/>
    </muxc:ItemsRepeater.Layout>
</muxc:ItemsRepeater>
```

Lifecycle events

When you host items in an ItemsRepeater, you might need to take some action when an item is shown or stops being shown, such as start an asynchronous download of some content, associate the element with a mechanism to track selection, or stop some background task.

In a virtualizing control, you cannot rely on Loaded/Unloaded events because the element might not be removed from the live visual tree when it's recycled. Instead, other events are provided to manage the lifecycle of elements. This diagram shows the lifecycle of an element in an ItemsRepeater, and when the related events are raised.



- **ElementPrepared** occurs each time an element is made ready for use. This occurs for both a newly created element as well as an element that already exists and is being re-used from the recycle queue.
- **ElementClearing** occurs immediately each time an element has been sent to the recycle queue, such as when it falls outside the range of realized items.
- **ElementIndexChanged** occurs for each realized UIElement where the index for the item it represents has changed. For example, when another item is added or removed in the data source, the index for items that come after in the ordering receive this event.

This example shows how you could use these events to attach a custom selection service to track item selection in a custom control that uses ItemsRepeater to display items.

XAML

```
<!-- xmlns:muxc="using:Microsoft.UI.Xaml.Controls" -->
<UserControl ...>
    ...
    <ScrollViewer>
        <muxc:ItemsRepeater ItemsSource="{x:Bind Items}"
                            ItemTemplate="{StaticResource MyTemplate}"
                            ElementPrepared="OnElementPrepared"
                            ElementIndexChanged="OnElementIndexChanged"
                            ElementClearing="OnElementClearing">
        </muxc:ItemsRepeater>
    </ScrollViewer>
    ...
</UserControl>
```

C#

```
interface ISelectable
{
    int SelectionIndex { get; set; }
    void UnregisterSelectionModel(SelectionModel selectionModel);
    void RegisterSelectionModel(SelectionModel selectionModel);
}

private void OnElementPrepared(ItemsRepeater sender,
ElementPreparedEventArgs args)
{
    var selectable = args.Element as ISelectable;
    if (selectable != null)
    {
        // Wire up this item to recognize a 'select' and listen for
programmatic
        // changes to the selection model to know when to update its visual
state.
        selectable.SelectionIndex = args.Index;
        selectable.RegisterSelectionModel(this.SelectionModel);
    }
}

private void OnElementIndexChanged(ItemsRepeater sender,
ElementIndexChangedEventArgs args)
{
    var selectable = args.Element as ISelectable;
    if (selectable != null)
    {
        // Sync the ID we use to notify the selection model when the item
        // we represent has changed location in the data source.
        selectable.SelectionIndex = args.NewIndex;
    }
}

private void OnElementClearing(ItemsRepeater sender,
ElementClearingEventArgs args)
{
    var selectable = args.Element as ISelectable;
    if (selectable != null)
    {
        // Disconnect handlers to recognize a 'select' and stop
        // listening for programmatic changes to the selection model.
        selectable.UnregisterSelectionModel(this.SelectionModel);
        selectable.SelectionIndex = -1;
    }
}
```

Sorting, Filtering and Resetting the Data

When you perform actions such as filtering or sorting your data set, you traditionally may have compared the previous set of data to the new data, then issued granular change notifications via INotifyCollectionChanged. However, it is often easier to completely replace the old data with the new data and trigger a collection change notification using the Reset action instead.

Typically, a reset causes a control to release existing child elements and start over, building the UI from the beginning at scroll position 0 as it has no awareness of exactly how the data has changed during the reset.

However, if the collection assigned as the ItemsSource supports unique identifiers by implementing the IKeyIndexMapping interface, then the ItemsRepeater can quickly identify:

- reusable UIElements for data that existed both before and after the reset
- previously visible items that were removed
- new items added that will be visible

This lets the ItemsRepeater avoid starting over from scroll position 0. It also lets it quickly restore the UIElements for data that didn't change in a reset, resulting in better performance.

This example shows how to display a list of items in a vertical stack where *MyItemsSource* is a custom data source that wraps an underlying list of items. It exposes a *Data* property that can be used to re-assign a new list to use as the items source, which then triggers a reset.

XAML

```
<ScrollViewer x:Name="sv">
    <ItemsRepeater x:Name="repeater"
                   ItemsSource="{x:Bind MyItemsSource}"
                   ItemTemplate="{StaticResource MyTemplate}">
       <ItemsRepeater.Layout>
           <StackLayout ItemSpacing="8"/>
       </ItemsRepeater.Layout>
   </ItemsRepeater>
</ScrollViewer>
```

C#

```
public MainPage()
{
    this.InitializeComponent();

    // Similar to an ItemsControl, a developer sets the ItemsRepeater's
```

```
ItemsSource.
    // Here we provide our custom source that supports unique IDs which
enables
    // ItemsRepeater to be smart about handling resets from the data.
    // Unique IDs also make it easy to do things apply sorting/filtering
    // without impacting any state (i.e. selection).
    MyItemsSource myItemsSource = new MyItemsSource(data);

    repeater.ItemsSource = myItemsSource;

    // ...

    // We can sort/filter the data using whatever mechanism makes the
    // most sense (LINQ, database query, etc.) and then reassign
    // it, which in our implementation triggers a reset.
    myItemsSource.Data = someNewData;
}

// ...

public class MyItemsSource : IReadOnlyList<ItemBase>, IKeyIndexMapping,
INotifyCollectionChanged
{
    private IList<ItemBase> _data;

    public MyItemsSource(IEnumerable<ItemBase> data)
    {
        if (data == null) throw new ArgumentNullException();

        this._data = data.ToList();
    }

    public IList<ItemBase> Data
    {
        get { return _data; }
        set
        {
            _data = value;

            // Instead of tossing out existing elements and re-creating
them,
            // ItemsRepeater will reuse the existing elements and match them
up
            // with the data again.
            this.CollectionChanged?.Invoke(
                this,
                new
NotifyCollectionChangedEventArgs(NotifyCollectionChangedAction.Reset));
        }
    }

    #region IReadOnlyList<T>

    public ItemBase this[int index] => this.Data != null
```

```
            ? this.Data[index]
            : throw new IndexOutOfRangeException();

        public int Count => this.Data != null ? this.Data.Count : 0;
        public IEnumerator<ItemBase> GetEnumerator() =>
this.Data.GetEnumerator();
        IEnumerator IEnumerable.GetEnumerator() => this.GetEnumerator();

        #endregion

        #region INotifyCollectionChanged

        public event NotifyCollectionChangedEventHandler CollectionChanged;

        #endregion

        #region IKeyIndexMapping

        private int lastRequestedIndex = IndexNotFound;
        private const int IndexNotFound = -1;

        // When UniqueIDs are supported, the ItemsRepeater caches the unique ID
for each item
        // with the matching UIElement that represents the item.  When a reset
occurs the
        // ItemsRepeater pairs up the already generated UIElements with items in
the data
        // source.
        // ItemsRepeater uses IndexForUniqueId after a reset to probe the data
and identify
        // the new index of an item to use as the anchor.  If that item no
        // longer exists in the data source it may try using another cached
unique ID until
        // either a match is found or it determines that all the previously
visible items
        // no longer exist.
        public int IndexForUniqueId(string uniqueId)
        {
            // We'll try to increase our odds of finding a match sooner by
starting from the
            // position that we know was last requested and search forward.
            var start = lastRequestedIndex;
            for (int i = start; i < this.Count; i++)
            {
                if (this[i].PrimaryKey.Equals(uniqueId))
                    return i;
            }

            // Then try searching backward.
            start = Math.Min(this.Count - 1, lastRequestedIndex);
            for (int i = start; i >= 0; i--)
            {
                if (this[i].PrimaryKey.Equals(uniqueId))
                    return i;
            }
```

```
        return IndexNotFound;
    }

    public string UniqueIdForIndex(int index)
    {
        var key = this[index].PrimaryKey;
        lastRequestedIndex = index;
        return key;
    }

    #endregion
}
```

Create a custom collection control

You can use the ItemsRepeater to create a custom collection control complete with its own type of control to present each item.

> **Note**
>
> This is similar to using **ItemsControl**, but instead of deriving from **ItemsControl** and putting an **ItemsPresenter** in the control template, you derive from **Control** and insert an **ItemsRepeater** in the control template. The custom collection control "has an" **ItemsRepeater** versus "is an" **ItemsControl**. This implies that you must also explicitly choose which properties to expose, rather than which inherited properties to not support.

This example shows how to place an ItemsRepeater in the template of a custom control named *MediaCollectionView* and expose its properties.

XAML

```
<!-- xmlns:muxc="using:Microsoft.UI.Xaml.Controls" -->
<Style TargetType="local:MediaCollectionView">
    <Setter Property="Template">
        <Setter.Value>
            <ControlTemplate TargetType="local:MediaCollectionView">
                <Border
                    Background="{TemplateBinding Background}"
                    BorderBrush="{TemplateBinding BorderBrush}"
                    BorderThickness="{TemplateBinding BorderThickness}">
                    <ScrollViewer x:Name="ScrollViewer">
                        <muxc:ItemsRepeater x:Name="ItemsRepeater"
                                            ItemsSource="{TemplateBinding
ItemsSource}"
```

```
                                                ItemTemplate="{TemplateBinding
ItemTemplate}"
                                                Layout="{TemplateBinding
Layout}"
                                                TabFocusNavigation="
{TemplateBinding TabFocusNavigation}"/>
                    </ScrollViewer>
                </Border>
            </ControlTemplate>
        </Setter.Value>
    </Setter>
</Style>
```

C#

```
public sealed class MediaCollectionView : Control
{
    public object ItemsSource
    {
        get { return (object)GetValue(ItemsSourceProperty); }
        set { SetValue(ItemsSourceProperty, value); }
    }

    // Using a DependencyProperty as the backing store for ItemsSource.
This enables animation, styling, binding, etc...
    public static readonly DependencyProperty ItemsSourceProperty =
        DependencyProperty.Register(nameof(ItemsSource), typeof(object),
typeof(MediaCollectionView), new PropertyMetadata(0));

    public DataTemplate ItemTemplate
    {
        get { return (DataTemplate)GetValue(ItemTemplateProperty); }
        set { SetValue(ItemTemplateProperty, value); }
    }

    // Using a DependencyProperty as the backing store for ItemTemplate.
This enables animation, styling, binding, etc...
    public static readonly DependencyProperty ItemTemplateProperty =
        DependencyProperty.Register(nameof(ItemTemplate),
typeof(DataTemplate), typeof(MediaCollectionView), new PropertyMetadata(0));

    public Layout Layout
    {
        get { return (Layout)GetValue(LayoutProperty); }
        set { SetValue(LayoutProperty, value); }
    }

    // Using a DependencyProperty as the backing store for Layout.  This
enables animation, styling, binding, etc...
    public static readonly DependencyProperty LayoutProperty =
        DependencyProperty.Register(nameof(Layout), typeof(Layout),
typeof(MediaCollectionView), new PropertyMetadata(0));
```

```
    public MediaCollectionView()
    {
        this.DefaultStyleKey = typeof(MediaCollectionView);
    }
}
```

Display grouped items

You can nest an ItemsRepeater in the ItemTemplate of another ItemsRepeater to create nested virtualizing layouts. The framework will make efficient use of resources by minimizing unnecessary realization of elements that aren't visible or near the current viewport.

This example shows how you can display a list of grouped items in a vertical stack. The outer ItemsRepeater generates each group. In the template for each group, another ItemsRepeater generates the items.

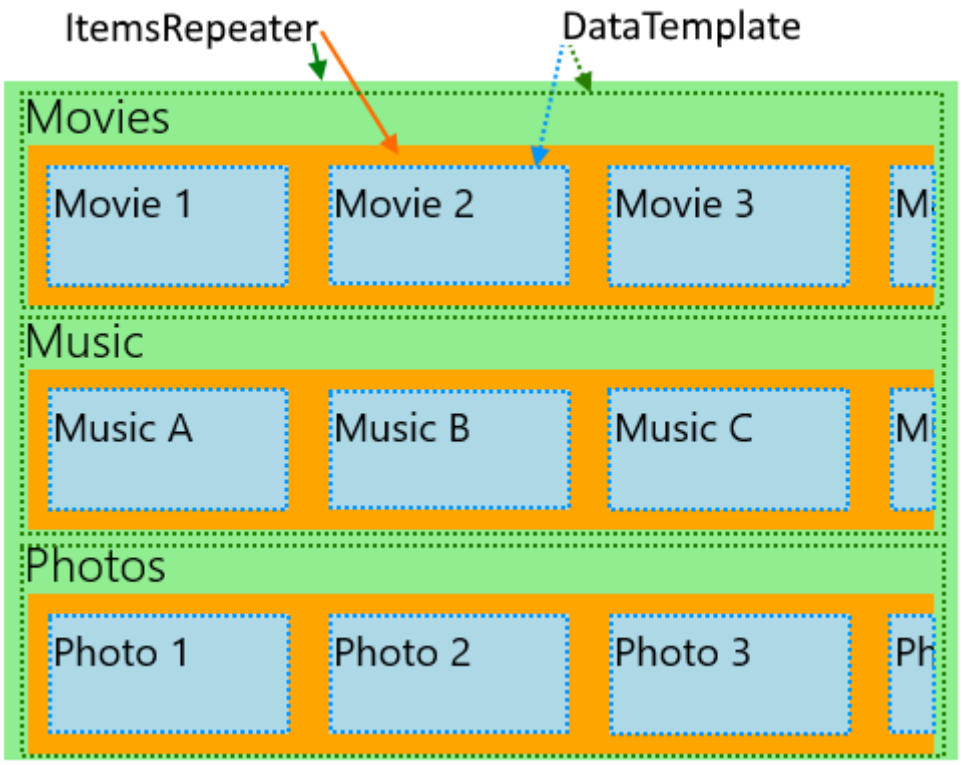
XAML

```
<!-- xmlns:muxc="using:Microsoft.UI.Xaml.Controls" -->

<Page.Resources>
    <muxc:StackLayout x:Key="MyGroupLayout"/>
    <muxc:StackLayout x:Key="MyItemLayout" Orientation="Horizontal"/>
</Page.Resources>

<ScrollViewer>
  <muxc:ItemsRepeater ItemsSource="{x:Bind AppNotifications}"
                      Layout="{StaticResource MyGroupLayout}">
    <muxc:ItemsRepeater.ItemTemplate>
      <DataTemplate x:DataType="ExampleApp:AppNotifications">
        <!-- Group -->
        <StackPanel>
          <!-- Header -->
          <TextBlock Text="{x:Bind AppTitle}"/>
          <!-- Items -->
          <muxc:ItemsRepeater ItemsSource="{x:Bind Notifications}"
                              Layout="{StaticResource MyItemLayout}"
                              ItemTemplate="{StaticResource MyTemplate}"/>
          <!-- Footer -->
          <Button Content="{x:Bind FooterText}"/>
        </StackPanel>
      </DataTemplate>
    </muxc:ItemsRepeater.ItemTemplate>
  </muxc:ItemsRepeater>
</ScrollViewer>
```

The image below shows the basic layout that's created using the above sample as a guideline.



This next example shows a layout for an app that has various categories that can change with user preference and are presented as horizontally scrolling lists. The layout of this example is also represented by the image above.

XAML

```
<!-- xmlns:muxc="using:Microsoft.UI.Xaml.Controls" -->
<!-- Include the <muxc:ItemsRepeaterScrollHost> if targeting Windows 10
versions earlier than 1809. -->
<ScrollViewer>
  <muxc:ItemsRepeater ItemsSource="{x:Bind Categories}"
                      Background="LightGreen">
    <muxc:ItemsRepeater.ItemTemplate>
      <DataTemplate x:DataType="local:Category">
        <StackPanel Margin="12,0">
          <TextBlock Text="{x:Bind Name}" Style="{ThemeResource
TitleTextBlockStyle}"/>
          <!-- Include the <muxc:ItemsRepeaterScrollHost> if targeting
Windows 10 versions earlier than 1809. -->
          <ScrollViewer HorizontalScrollMode="Enabled"
                                      VerticalScrollMode="Disabled"

HorizontalScrollBarVisibility="Auto" >
            <muxc:ItemsRepeater ItemsSource="{x:Bind Items}"
                                Background="Orange">
              <muxc:ItemsRepeater.ItemTemplate>
                <DataTemplate x:DataType="local:CategoryItem">
                  <Grid Margin="10"
```

```
                        Height="60" Width="120"
                        Background="LightBlue">
                    <TextBlock Text="{x:Bind Name}"
                               Style="{StaticResource
SubtitleTextBlockStyle}"
                               Margin="4"/>
                  </Grid>
                </DataTemplate>
              </muxc:ItemsRepeater.ItemTemplate>
              <muxc:ItemsRepeater.Layout>
                <muxc:StackLayout Orientation="Horizontal"/>
              </muxc:ItemsRepeater.Layout>
            </muxc:ItemsRepeater>
          </ScrollViewer>
        </StackPanel>
      </DataTemplate>
    </muxc:ItemsRepeater.ItemTemplate>
  </muxc:ItemsRepeater>
</ScrollViewer>
```

Bringing an Element Into View

The XAML framework already handles bringing a FrameworkElement into view when it either 1) receives keyboard focus or 2) receives Narrator focus. There may be other cases where you need to explicitly bring an element into view. For example, in response to a user action or to restore the state of the UI after a page navigation.

Bringing a virtualized element into view involves the following:

1. Realize a UIElement for an item
2. Run the layout to ensure the element has a valid position
3. Initiate a request to bring the realized element into view

The example below demonstrates these steps as part of restoring the scroll position of an item in a flat, vertical list after a page navigation. In the case of hierarchical data using nested ItemsRepeaters the approach is essentially the same, but must be done at each level of the hierarchy.

XAML

```
<ScrollViewer x:Name="scrollviewer">
  <ItemsRepeater x:Name="repeater" .../>
</ScrollViewer>
```

C#

```
public class MyPage : Page
{
    // ...

     protected override void OnNavigatedTo(NavigationEventArgs e)
    {
        base.OnNavigatedTo(e);

        // retrieve saved offset + index(es) of the tracked element and then
bring it into view.
        // ...

        var element = repeater.GetOrCreateElement(index);

        // ensure the item is given a valid position
        element.UpdateLayout();

        element.StartBringIntoView(new BringIntoViewOptions()
        {
            VerticalOffset = relativeVerticalOffset
        });
    }

    protected override void OnNavigatingFrom(NavigatingCancelEventArgs e)
    {
        base.OnNavigatingFrom(e);

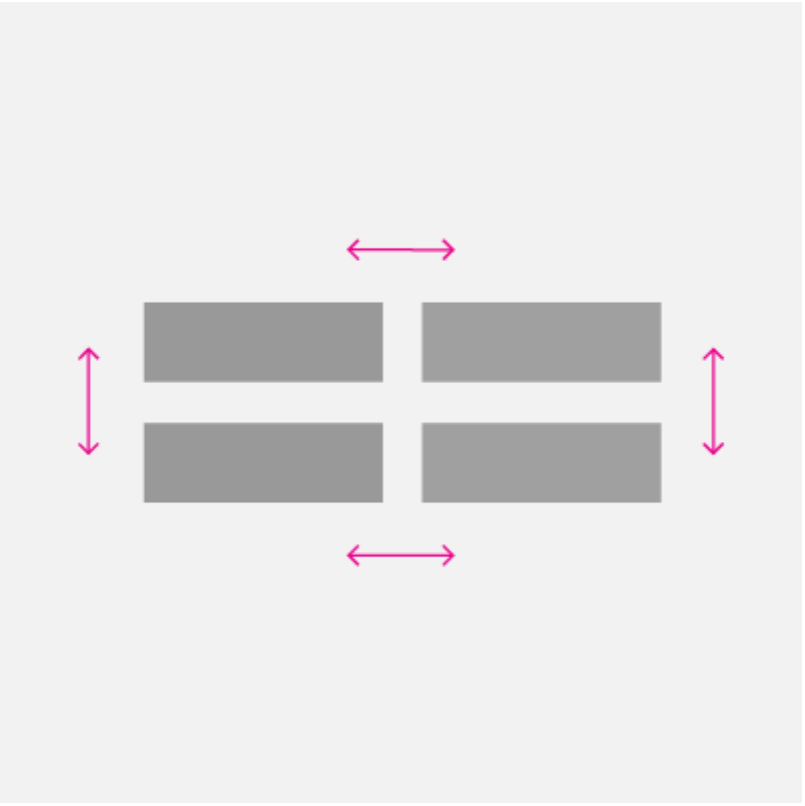
        // retrieve and save the relative offset and index(es) of the
scrollviewer's current anchor element ...
        var anchor = this.scrollviewer.CurrentAnchor;
        var index = this.repeater.GetElementIndex(anchor);
        var anchorBounds =
anchor.TransformToVisual(this.scrollviewer).TransformBounds(new Rect(0, 0,
anchor.ActualSize.X, anchor.ActualSize.Y));
        relativeVerticalOffset = this.scrollviewer.VerticalOffset -
anchorBounds.Top;
    }
}
```

Enable Accessibility

ItemsRepeater does not provide a default accessibility experience. The documentation on Usability for Windows apps provides a wealth of information to help you ensure your app provides an inclusive user experience. If you're using the ItemsRepeater to create a custom control then be sure to see the documentation on Custom automation peers.

Keyboarding

The minimal keyboarding support for focus movement that ItemsRepeater provides is based on XAML's 2D Directional Navigation for Keyboarding.



The ItemsRepeater's XYFocusKeyboardNavigation mode is *Enabled* by default. Depending on the intended experience, consider adding support for common Keyboard Interactions such as Home, End, PageUp, and PageDown.

The ItemsRepeater does automatically ensure that the default tab order for its items (whether virtualized or not) follows the same order that the items are given in the data. By default the ItemsRepeater has its TabFocusNavigation property set to Once instead of the common default of *Local*.

> **Note**
>
> The ItemsRepeater does not automatically remember the last focused item. This means that when a user is using Shift+Tab they may be taken to the last realized item.

Announcing "Item *X* of *Y*" in Screen Readers

You need to manage setting the appropriate automation properties, such as values for **PositionInSet** and **SizeOfSet**, and ensure they remain up-to-date when items are added, moved, removed, etc.

In some custom layouts there may not be an obvious sequence to the visual order. Users minimally expect that the values for the PositionInSet and SizeOfSet properties used by screen readers will match the order the items appear in the data (offset by 1 to match natural counting versus being 0-based).

The best way to achieve this is by having the automation peer for the item control implement the GetPositionInSetCore and GetSizeOfSetCore methods and report the position of the item in the data set represented by the control. The value is only computed at run-time when accessed by an assistive technology and keeping it up-to-date becomes a non-issue. The value matches the data order.

This example shows how you could do this when presenting a custom control called *CardControl*.

XAML

```
<ScrollViewer >
    <ItemsRepeater x:Name="repeater" ItemsSource="{x:Bind MyItemsSource}">
       <ItemsRepeater.ItemTemplate>
           <DataTemplate x:DataType="local:CardViewModel">
               <local:CardControl Item="{x:Bind}"/>
           </DataTemplate>
       </ItemsRepeater.ItemTemplate>
   </ItemsRepeater>
</ScrollViewer>
```

C#

```
internal sealed class CardControl : CardControlBase
{
    protected override AutomationPeer OnCreateAutomationPeer() => new
CardControlAutomationPeer(this);

    private sealed class CardControlAutomationPeer :
FrameworkElementAutomationPeer
    {
        private readonly CardControl owner;

        public CardControlAutomationPeer(CardControl owner) : base(owner) =>
this.owner = owner;

        protected override int GetPositionInSetCore()
          => ((ItemsRepeater)owner.Parent)?.GetElementIndex(this.owner) + 1
?? base.GetPositionInSetCore();

        protected override int GetSizeOfSetCore()
          => ((ItemsRepeater)owner.Parent)?.ItemsSourceView?.Count ??
base.GetSizeOfSetCore();
```

```
    }
}
```

UWP and WinUI 2

> **Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

The ItemsRepeater for UWP apps requires WinUI 2. For more info, including installation instructions, see WinUI 2. APIs for this control exist in the Microsoft.UI.Xaml.Controls namespace.

- ✓ **UWP APIs:** ScrollViewer class
- ✓ **WinUI 2 Apis:** ItemsRepeater class
- ✓ Open the WinUI 2 Gallery app and see the ItemsRepeater in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

To use the code in this article with WinUI 2, use an alias in XAML (we use `muxc`) to represent the Windows UI Library APIs that are included in your project. See Get Started with WinUI 2 for more info.

XAML

```
xmlns:muxc="using:Microsoft.UI.Xaml.Controls"

<muxc:ItemsRepeater />
```

Item containers and templates

Article • 06/09/2022

ListView and **GridView** controls manage how their items are arranged (horizontal, vertical, wrapping, etc...) and how a user interacts with the items, but not how the individual items are shown on the screen. Item visualization is managed by item containers. When you add items to a list view they are automatically placed in a container. The default item container for ListView is ListViewItem; for GridView, it's GridViewItem.

> **Important APIs**: ListView class, GridView class, ListViewItem class, GridViewItem class, ItemTemplate property, ItemContainerStyle property

> **Note**
>
> ListView and GridView both derive from the **ListViewBase** class, so they have the same functionality, but display data differently. In this article, when we talk about list view, the info applies to both the ListView and GridView controls unless otherwise specified. We may refer to classes like ListView or ListViewItem, but the *List* prefix can be replaced with *Grid* for the corresponding grid equivalent (GridView or GridViewItem).

ListView items and GridView items

As mentioned above, ListView items are automatically placed into the ListViewItem container, and GridView items are placed into the GridViewItem container. These item containers are controls that have their own built-in styling and interaction, but can also be highly customized. However, before customization, make sure to familizarize yourself with the recommended styling and guidelines for ListViewItem and GridViewItem:

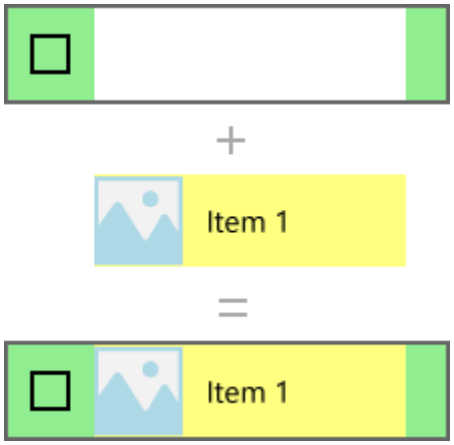
- **ListViewItems** - Items are primarily text-focused, and elongated in shape. Icons or images may appear to the left of the text.
- **GridViewItems** - Items are usually square in shape, or at least less of an elongated rectangle shape. Items are image-focused, and may have text appearing around or overlaid on the image.

Introduction to customization

Container controls (such as ListViewItem and GridViewItem) consist of two important parts that combine to create the final visuals shown for an item: the *data template* and the *control template*.

- **Data template** - You assign a DataTemplate to the ItemTemplate property of the list view to specify how individual data items are shown.
- **Control template** - The control template provides the part of the item visualization that the framework is responsible for, like visual states. You can use the ItemContainerStyle property to modify the control template. Typically, you do this to modify the list view colors to match your branding, or change how selected items are shown.

This image shows how the control template and the data template combine to create the final visual for an item.



Here's the XAML that creates this item. We explain the templates later.

XAML

```
<ListView Width="220" SelectionMode="Multiple">
    <ListView.ItemTemplate>
        <DataTemplate x:DataType="x:String">
            <Grid Background="Yellow">
                <Grid.ColumnDefinitions>
                    <ColumnDefinition Width="54"/>
                    <ColumnDefinition/>
                </Grid.ColumnDefinitions>
                <Image Source="Assets/placeholder.png" Width="44"
Height="44"
                       HorizontalAlignment="Left"/>
                <TextBlock Text="{x:Bind}" Foreground="Black"
                           FontSize="14" Grid.Column="1"
                           VerticalAlignment="Center"
                           Padding="0,0,54,0"/>
            </Grid>
        </DataTemplate>
    </ListView.ItemTemplate>
    <ListView.ItemContainerStyle>
```

```
        <Style TargetType="ListViewItem">
            <Setter Property="Background" Value="LightGreen"/>
        </Style>
    </ListView.ItemContainerStyle>
    <x:String>Item 1</x:String>
    <x:String>Item 2</x:String>
    <x:String>Item 3</x:String>
    <x:String>Item 4</x:String>
    <x:String>Item 5</x:String>
</ListView>
```

> **Important**
>
> Data templates and control templates are used to customize the style for many controls other than ListView and GridView. These include controls with their own built-in styling, such as FlipView, and custom-created controls, such as ItemsRepeater. While the below example is specific to ListView/GridView, the concepts can be applied to many other controls.

Prerequisites

- We assume that you know how to use a list view control. For more info, see the ListView and GridView article.
- We also assume that you understand control styles and templates, including how to use a style inline or as a resource. For more info, see Styling controls and Control templates.

The data

Before we look deeper into how to show data items in a list view, we need to understand the data to be shown. In this example, we create a data type called `NamedColor`. It combines a color name, color value, and a **SolidColorBrush** for the color, which are exposed as 3 properties: `Name`, `Color`, and `Brush`.

We then populate a **List** with a `NamedColor` object for each named color in the Colors class. The list is set as the ItemsSource for the list view.

Here's the code to define the class and populate the `NamedColors` list.

C#

```
C#
```

```
using System.Collections.Generic;
using System.Linq;
using System.Reflection;
using Windows.UI;
using Windows.UI.Xaml.Controls;
using Windows.UI.Xaml.Media;

namespace ColorsListApp
{
    public sealed partial class MainPage : Page
    {
        // The list of colors won't change after it's populated, so we use
List<T>.
        // If the data can change, we should use an ObservableCollection<T>
intead.
        List<NamedColor> NamedColors = new List<NamedColor>();

        public MainPage()
        {
            this.InitializeComponent();

            // Use reflection to get all the properties of the Colors class.
            IEnumerable<PropertyInfo> propertyInfos =
typeof(Colors).GetRuntimeProperties();

            // For each property, create a NamedColor with the property name
(color name),
            // and property value (color value). Add it the NamedColors
list.
            for (int i = 0; i < propertyInfos.Count(); i++)
            {
                NamedColors.Add(new
NamedColor(propertyInfos.ElementAt(i).Name,

(Color)propertyInfos.ElementAt(i).GetValue(null)));
            }

            colorsListView.ItemsSource = NamedColors;
        }
    }

    class NamedColor
    {
        public NamedColor(string colorName, Color colorValue)
        {
            Name = colorName;
            Color = colorValue;
        }

        public string Name { get; set; }

        public Color Color { get; set; }

        public SolidColorBrush Brush
```

```
        {
            get { return new SolidColorBrush(Color); }
        }
    }
}
```

Data template

You specify a data template to tell the list view how your data item should be shown.

By default, a data item is displayed in the list view as the string representation of the data object it's bound to. If you show the 'NamedColors' data in a list view without telling the list view how it should look, it just shows whatever the **ToString** method returns, like this.

XAML

XAML

```
<ListView x:Name="colorsListView"/>
```

ColorsListApp.NamedColor

ColorsListApp.NamedColor

ColorsListApp.NamedColor

ColorsListApp.NamedColor

ColorsListApp.NamedColor

You can show the string representation of a particular property of the data item by setting the DisplayMemberPath to that property. Here, you set DisplayMemberPath to the `Name` property of the `NamedColor` item.

XAML

XAML

```
<ListView x:Name="colorsListView" DisplayMemberPath="Name" />
```

The list view now displays items by name, as shown here. It's more useful, but it's not very interesting and leaves a lot of information hidden.

Blue

BlueViolet

Brown

BurlyWood

CadetBlue

You typically want to show a more rich presentation of your data. To specify exactly how items in the list view are displayed, you create a DataTemplate. The XAML in the DataTemplate defines the layout and appearance of controls used to display an individual item. The controls in the layout can be bound to properties of a data object, or have static content defined inline. You assign the DataTemplate to the ItemTemplate property of the list control.

> **ⓘ Important**
>
> You can't use a **ItemTemplate** and **DisplayMemberPath** at the same time. If both properties are set, an exception occurs.

Here, you define a DataTemplate that shows a Rectangle in the color of the item, along with the color name and RGB values.

> **ⓘ Note**
>
> When you use the **x:Bind markup extension** in a DataTemplate, you have to specify the DataType (`x:DataType`) on the DataTemplate.

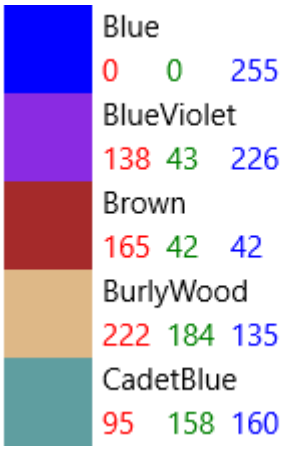
XAML

XAML

```
<ListView x:Name="colorsListView">
    <ListView.ItemTemplate>
        <DataTemplate x:DataType="local:NamedColor">
            <Grid>
                <Grid.ColumnDefinitions>
                    <ColumnDefinition MinWidth="54"/>
                    <ColumnDefinition Width="32"/>
                    <ColumnDefinition Width="32"/>
                    <ColumnDefinition Width="32"/>
                    <ColumnDefinition/>
```

```
                </Grid.ColumnDefinitions>
                <Grid.RowDefinitions>
                    <RowDefinition/>
                    <RowDefinition/>
                </Grid.RowDefinitions>
                <Rectangle Width="44" Height="44" Fill="{x:Bind Brush}"
Grid.RowSpan="2"/>
                <TextBlock Text="{x:Bind Name}" Grid.Column="1"
Grid.ColumnSpan="4"/>
                <TextBlock Text="{x:Bind Color.R}" Grid.Column="1"
Grid.Row="1" Foreground="Red"/>
                <TextBlock Text="{x:Bind Color.G}" Grid.Column="2"
Grid.Row="1" Foreground="Green"/>
                <TextBlock Text="{x:Bind Color.B}" Grid.Column="3"
Grid.Row="1" Foreground="Blue"/>
            </Grid>
        </DataTemplate>
    </ListView.ItemTemplate>
</ListView>
```

Here's what the data items look like when they're displayed with this data template.



> **ⓘ Important**
>
> ListViewItems by default have their content aligned left, i.e. their HorizontalContentAlignmentProperty is set to Left. If you have multiple elements within a ListViewItem that are horizontally adjacent, such as horizontally stacked elements or elements placed in the same Grid row, they will all be left-aligned and only separated by their defined margin.
>
> In order to have elements spread to fill the entire body of a ListItem, you will need to set the HorizontalContentAlignmentProperty to Stretch by using a Setter inside of your ListView:

XAML

```
<ListView.ItemContainerStyle>
    <Style TargetType="ListViewItem">
        <Setter Property="HorizontalContentAlignment" Value="Stretch"/>
    </Style>
</ListView.ItemContainerStyle>
```

You might want to show the data in a GridView. Here's another data template that displays the data in a way that's more appropriate for a grid layout. This time, the data template is defined as a resource rather than inline with the XAML for the GridView.

XAML

XAML

```
<Page.Resources>
    <DataTemplate x:Key="namedColorItemGridTemplate"
x:DataType="local:NamedColor">
        <Grid>
            <Grid.ColumnDefinitions>
                <ColumnDefinition Width="32"/>
                <ColumnDefinition Width="32"/>
                <ColumnDefinition Width="32"/>
            </Grid.ColumnDefinitions>
            <Grid.RowDefinitions>
                <RowDefinition Height="96"/>
                <RowDefinition/>
                <RowDefinition/>
            </Grid.RowDefinitions>

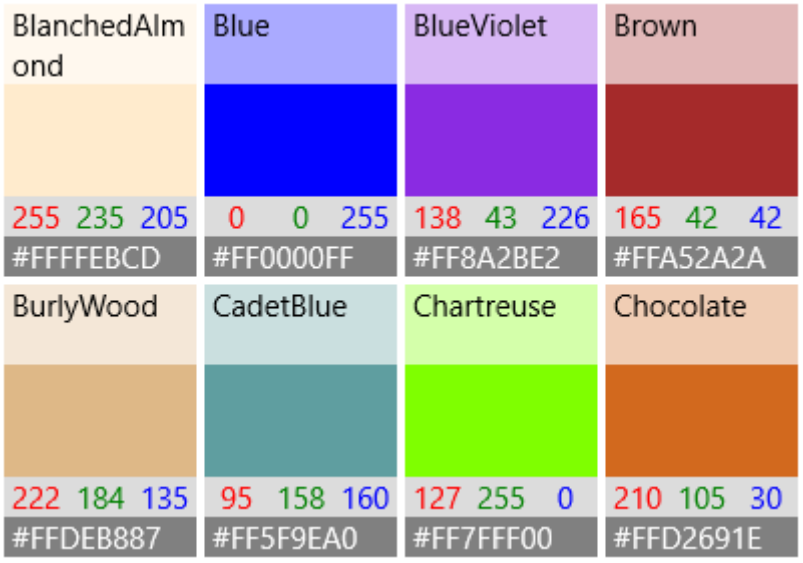
            <Rectangle Width="96" Height="96" Fill="{x:Bind Brush}"
Grid.ColumnSpan="3" />
            <!-- Name -->
            <Border Background="#AAFFFFFF" Grid.ColumnSpan="3" Height="40"
VerticalAlignment="Top">
                <TextBlock Text="{x:Bind Name}" TextWrapping="Wrap"
Margin="4,0,0,0"/>
            </Border>
            <!-- RGB -->
            <Border Background="Gainsboro" Grid.Row="1"
Grid.ColumnSpan="3"/>
            <TextBlock Text="{x:Bind Color.R}" Foreground="Red"
                   Grid.Column="0" Grid.Row="1"
HorizontalAlignment="Center"/>
            <TextBlock Text="{x:Bind Color.G}" Foreground="Green"
                   Grid.Column="1" Grid.Row="1"
HorizontalAlignment="Center"/>
            <TextBlock Text="{x:Bind Color.B}" Foreground="Blue"
                   Grid.Column="2" Grid.Row="1"
HorizontalAlignment="Center"/>
            <!-- HEX -->
            <Border Background="Gray" Grid.Row="2" Grid.ColumnSpan="3">
```

```
                <TextBlock Text="{x:Bind Color}" Foreground="White"
Margin="4,0,0,0"/>
            </Border>
        </Grid>
    </DataTemplate>
</Page.Resources>

...

<GridView x:Name="colorsGridView"
          ItemTemplate="{StaticResource namedColorItemGridTemplate}"/>
```

When the data is shown in a grid using this data template, it looks like this.



Performance considerations

Data templates are the primary way you define the look of your list view. They can also have a significant impact on performance if your list displays a large number of items.

An instance of every XAML element in a data template is created for each item in the list view. For example, the grid template in the previous example has 10 XAML elements (1 Grid, 1 Rectangle, 3 Borders, 5 TextBlocks). A GridView that shows 20 items on screen using this data template creates at least 200 elements (20*10=200). Reducing the number of elements in a data template can greatly reduce the total number of elements created for your list view. For more info, see ListView and GridView UI optimization: Element count reduction per item.

Consider this section of the grid data template. Let's look at a few things that reduce the element count.

XAML

```
```

XAML

```
<!-- RGB -->
<Border Background="Gainsboro" Grid.Row="1" Grid.ColumnSpan="3"/>
<TextBlock Text="{x:Bind Color.R}" Foreground="Red"
           Grid.Column="0" Grid.Row="1" HorizontalAlignment="Center"/>
<TextBlock Text="{x:Bind Color.G}" Foreground="Green"
           Grid.Column="1" Grid.Row="1" HorizontalAlignment="Center"/>
<TextBlock Text="{x:Bind Color.B}" Foreground="Blue"
           Grid.Column="2" Grid.Row="1" HorizontalAlignment="Center"/>
```

- First, the layout uses a single Grid. You could have a single-column Grid and place these 3 TextBlocks in a StackPanel, but in a data template that gets created many times, you should look for ways to avoid embedding layout panels within other layout panels.
- Second, you can use a Border control to render a background without actually placing items within the Border element. A Border element can have only one child element, so you would need to add an additional layout panel to host the 3 TextBlock elements within the Border element in XAML. By not making the TextBlocks children of the Border, you eliminate the need for a panel to hold the TextBlocks.
- Finally, you could place the TextBlocks inside a StackPanel, and set the border properties on the StackPanel rather than using an explicit Border element. However, the Border element is a more lightweight control than a StackPanel, so it has less of an impact on performance when rendered many times over.

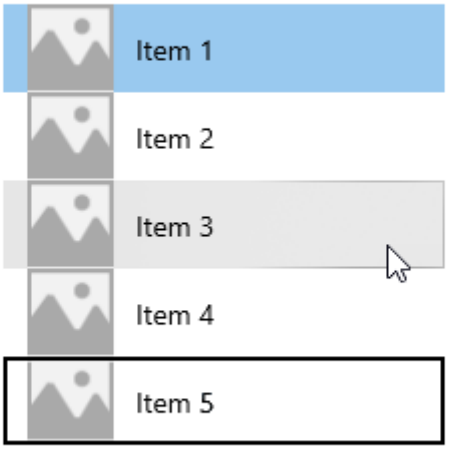
Using different layouts for different items

Control template

An item's control template contains the visuals that display state, like selection, pointer over, and focus. These visuals are rendered either on top of or below the data template. Some of the common default visuals drawn by the ListView control template are shown here.

- Hover – A light gray rectangle drawn below the data template.
- Selection – A light blue rectangle drawn below the data template.
- Keyboard focus– A High Visibility Focus Visual drawn on top of the item template.

The list view combines the elements from the data template and control template to create the final visuals rendered on the screen. Here, the state visuals are shown in the context of a list view.



ListViewItemPresenter

As we noted previously about data templates, the number of XAML elements created for each item can have a significant impact on the performance of a list view. Because the data template and control template are combined to display each item, the actual number of elements needed to display an item includes the elements in both templates.

The ListView and GridView controls are optimized to reduce the number of XAML elements created per item. The **ListViewItem** visuals are created by the ListViewItemPresenter, which is a special XAML element that displays complex visuals for focus, selection, and other visual states, without the overhead of numerous UIElements.

> **Note**

In UWP apps for Windows, both **ListViewItem** and **GridViewItem** use **ListViewItemPresenter**; the GridViewItemPresenter is deprecated and you should not use it. ListViewItem and GridViewItem set different property values on ListViewItemPresenter to achieve different default looks.)

To modify the look of the item container, use the ItemContainerStyle property and provide a Style with its TargetType set to **ListViewItem** or **GridViewItem**.

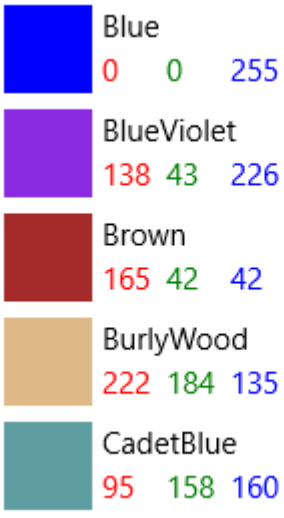
In this example, you add padding to the ListViewItem to create some space between the items in the list.

XAML

```
<ListView x:Name="colorsListView">
    <ListView.ItemTemplate>
        <!-- DataTemplate XAML shown in previous ListView example -->
    </ListView.ItemTemplate>

    <ListView.ItemContainerStyle>
        <Style TargetType="ListViewItem">
            <Setter Property="Padding" Value="0,4"/>
        </Style>
    </ListView.ItemContainerStyle>
</ListView>
```

Now the list view looks like this with space between the items.



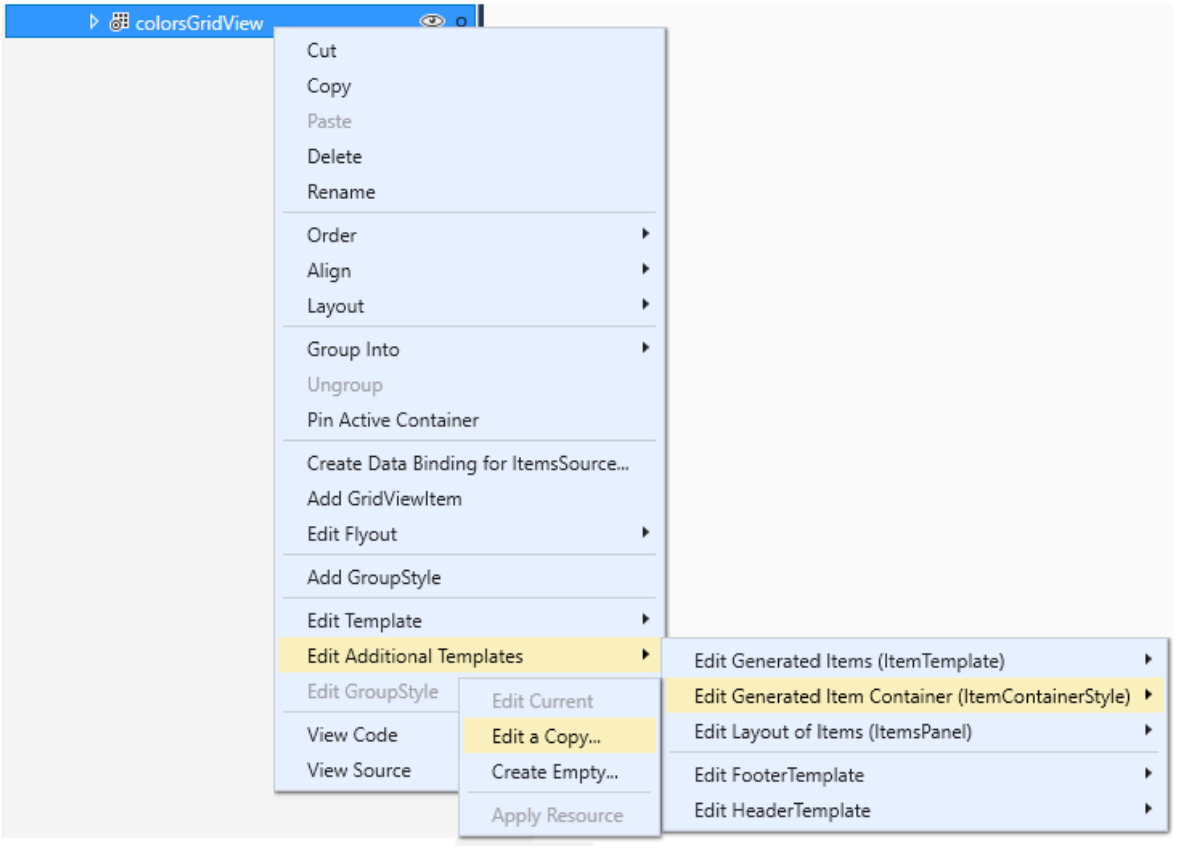
In the ListViewItem default style, the ListViewItemPresenter **ContentMargin** property has a TemplateBinding to the ListViewItem **Padding** property (`<ListViewItemPresenter ContentMargin="{TemplateBinding Padding}"/>`). When we set the Padding property, that value is really being passed to the ListViewItemPresenter ContentMargin property.

To modify other ListViewItemPresenter properties that aren't template bound to ListViewItems properties, you need to retemplate the ListViewItem with a new ListViewItemPresenter that you can modify properties on.

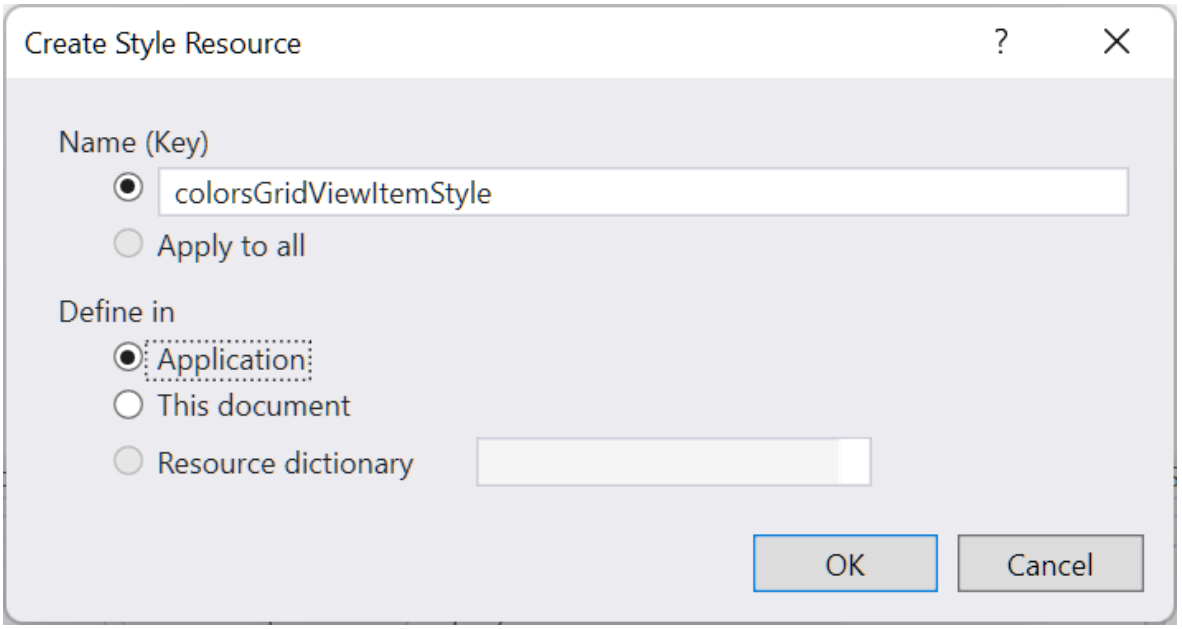
> **Note**
>
> ListViewItem and GridViewItem default styles set a lot of properties on ListViewItemPresenter. You should always start with a copy of the default style and modify only the properties you need too. Otherwise, the visuals will probably not show up the way you expect because some properties won't be set correctly.

To make a copy of the default template in Visual Studio

1. Open the Document Outline pane (**View** > **Other Windows** > **Document Outline**).
2. Select the list or grid element to modify. In this example, you modify the `colorsGridView` element.
3. Right-click and select **Edit Additional Templates** > **Edit Generated Item Container (ItemContainerStyle)** > **Edit a Copy**.



4. In the Create Style Resource dialog, enter a name for the style. In this example, you use `colorsGridViewItemStyle`.



A copy of the default style is added to your app as a resource, and the **GridView.ItemContainerStyle** property is set to that resource, as shown in this XAML.

XAML

```
<Style x:Key="colorsGridViewItemStyle" TargetType="GridViewItem">
    <Setter Property="FontFamily" Value="{ThemeResource
ContentControlThemeFontFamily}"/>
    <Setter Property="FontSize" Value="{ThemeResource
ControlContentThemeFontSize}" />
    <Setter Property="Background" Value="Transparent"/>
    <Setter Property="Foreground" Value="{ThemeResource
SystemControlForegroundBaseHighBrush}"/>
    <Setter Property="TabNavigation" Value="Local"/>
    <Setter Property="IsHoldingEnabled" Value="True"/>
    <Setter Property="HorizontalContentAlignment" Value="Center"/>
    <Setter Property="VerticalContentAlignment" Value="Center"/>
    <Setter Property="Margin" Value="0,0,4,4"/>
    <Setter Property="MinWidth" Value="{ThemeResource
GridViewItemMinWidth}"/>
    <Setter Property="MinHeight" Value="{ThemeResource
GridViewItemMinHeight}"/>
    <Setter Property="Template">
        <Setter.Value>
            <ControlTemplate TargetType="GridViewItem">
                <ListViewItemPresenter
                    CheckBrush="{ThemeResource
SystemControlForegroundBaseMediumHighBrush}"
                    ContentMargin="{TemplateBinding Padding}"
                    CheckMode="Overlay"
                    ContentTransitions="{TemplateBinding
ContentTransitions}"
                    CheckBoxBrush="{ThemeResource
SystemControlBackgroundChromeMediumBrush}"
                    DragForeground="{ThemeResource
ListViewItemDragForegroundThemeBrush}"
```

```
                    DragOpacity="{ThemeResource
ListViewItemDragThemeOpacity}"
                    DragBackground="{ThemeResource
ListViewItemDragBackgroundThemeBrush}"
                    DisabledOpacity="{ThemeResource
ListViewItemDisabledThemeOpacity}"
                    FocusBorderBrush="{ThemeResource
SystemControlForegroundAltHighBrush}"
                    FocusSecondaryBorderBrush="{ThemeResource
SystemControlForegroundBaseHighBrush}"
                    HorizontalContentAlignment="{TemplateBinding
HorizontalContentAlignment}"
                    PointerOverForeground="{ThemeResource
SystemControlForegroundBaseHighBrush}"
                    PressedBackground="{ThemeResource
SystemControlHighlightListMediumBrush}"
                    PlaceholderBackground="{ThemeResource
ListViewItemPlaceholderBackgroundThemeBrush}"
                    PointerOverBackground="{ThemeResource
SystemControlHighlightListLowBrush}"
                    ReorderHintOffset="{ThemeResource
GridViewItemReorderHintThemeOffset}"
                    SelectedPressedBackground="{ThemeResource
SystemControlHighlightListAccentHighBrush}"
                    SelectionCheckMarkVisualEnabled="True"
                    SelectedForeground="{ThemeResource
SystemControlForegroundBaseHighBrush}"
                    SelectedPointerOverBackground="{ThemeResource
SystemControlHighlightListAccentMediumBrush}"
                    SelectedBackground="{ThemeResource
SystemControlHighlightAccentBrush}"
                    VerticalContentAlignment="{TemplateBinding
VerticalContentAlignment}"/>
            </ControlTemplate>
        </Setter.Value>
    </Setter>
</Style>

...

<GridView x:Name="colorsGridView" ItemContainerStyle="{StaticResource
colorsGridViewItemStyle}"/>
```

You can now modify properties on the ListViewItemPresenter to control the selection check box, item positioning, and brush colors for visual states.

Inline and Overlay selection visuals

ListView and GridView indicate selected items in different ways depending on the control and the SelectionMode. For more info about list view selection, see ListView and GridView.

When **SelectionMode** is set to **Multiple**, a selection check box is shown as part of the item's control template. You can use the SelectionCheckMarkVisualEnabled property to turn off the selection check box in Multiple selection mode. However, this property is ignored in other selection modes, so you can't turn on the check box in Extended or Single selection mode.

You can set the CheckMode property to specify whether the check box is shown using the inline style or overlay style.

- **Inline**: This style shows the check box to the left of the content, and colors the background of the item container to indicate selection. This is the default style for ListView.
- **Overlay**: This style shows the check box on top of the content, and colors only the border of the item container to indicate selection. This is the default style for GridView.

This table shows the default visuals used to indicate selection.

Expand table

SelectionMode:	Single/Extended	Multiple
Inline		Overlay		
Note

In this and the following examples, simple string data items are shown without data templates to emphasize the visuals provided by the control template.

There are also several brush properties to change the colors of the check box. We'll look at these next along with other brush properties.

Brushes

Many of the properties specify the brushes used for different visual states. You might want to modify these to match the color of your brand.

This table shows the Common and Selection visual states for ListViewItem, and the brushes used to render the visuals for each state. The images show the effects of the brushes on both the inline and overlay selection visual styles.

> **Note**
>
> In this table, the modified color values for the brushes are hardcoded named colors and the colors are selected to make it more apparent where they are applied in the template. These are not the default colors for the visual states. If you modify the default colors in your app, you should use brush resources to modify the color values as done in the default template.

Expand table

State/Brush name	Inline style	Overlay style
Normal • **CheckBoxBrush="Red"**		
PointerOver • **PointerOverForeground="DarkOrange"** • **PointerOverBackground="MistyRose"** • CheckBoxBrush="Red"		
Pressed • **PressedBackground="LightCyan"** • PointerOverForeground="DarkOrange"		

State/Brush name	Inline style	Overlay style
• CheckBoxBrush="Red"		
Selected • **SelectedForeground="Navy"** • **SelectedBackground="Khaki"** • **CheckBrush="Green"** • CheckBoxBrush="Red" (inline only)		
PointerOverSelected • **SelectedPointerOverBackground="Lavender"** • SelectedForeground="Navy" • SelectedBackground="Khaki" (overlay only) • CheckBrush="Green" • CheckBoxBrush="Red" (inline only)		
PressedSelected • **SelectedPressedBackground="MediumTurquoise"** • SelectedForeground="Navy" • SelectedBackground="Khaki" (overlay only) • CheckBrush="Green" • CheckBoxBrush="Red" (inline only)		
Focused • **FocusBorderBrush="Crimson"** • **FocusSecondaryBorderBrush="Gold"** • CheckBoxBrush="Red"		

ListViewItemPresenter has other brush properties for data placeholders and drag states. If you use incremental loading or drag and drop in your list view, you should consider whether you need to also modify these additional brush properties. See the ListViewItemPresenter class for the complete list of properties you can modify.

Expanded XAML item templates

If you need to make more modifications than what is allowed by the **ListViewItemPresenter** properties - if you need to change the position of the check box, for example - you can use the *ListViewItemExpanded* or *GridViewItemExpanded*

templates. These templates are included with the default styles in generic.xaml. They follow the standard XAML pattern of building all the visuals from individual UIElements.

As mentioned previously, the number of UIElements in an item template has a significant impact on the performance of your list view. Replacing ListViewItemPresenter with the expanded XAML templates greatly increases the element count, and is not recommended when your list view will show a large number of items or when performance is a concern.

> **Note**
>
> **ListViewItemPresenter** is supported only when the list view's ItemsPanel is an ItemsWrapGrid or ItemsStackPanel. If you change the ItemsPanel to use VariableSizedWrapGrid, WrapGrid, or StackPanel, then the item template is automatically switched to the expanded XAML template. For more info, see ListView and GridView UI optimization.

To customize an expanded XAML template, you need to make a copy of it in your app, and set the **ItemContainerStyle** property to your copy.

To copy the expanded template

1. Set the ItemContainerStyle property as shown here for your ListView or GridView.

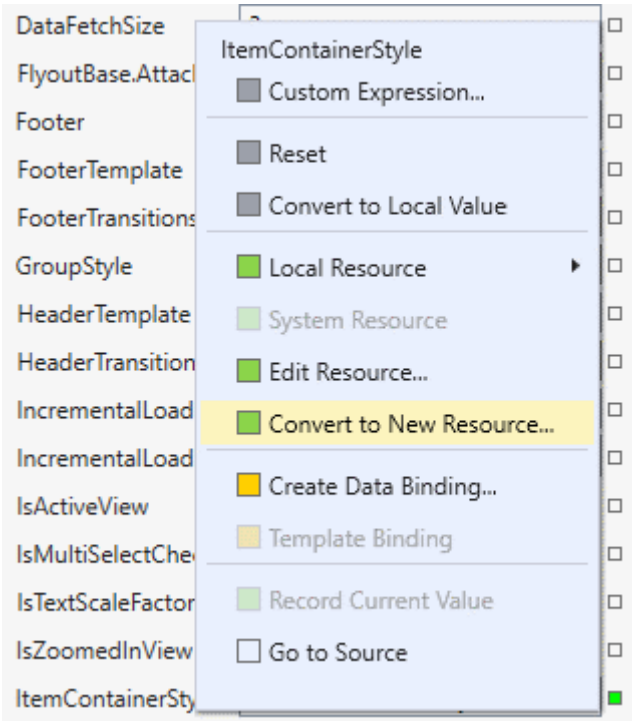
   XAML

   ```
   <ListView ItemContainerStyle="{StaticResource ListViewItemExpanded}"/>
   <GridView ItemContainerStyle="{StaticResource GridViewItemExpanded}"/>
   ```

2. In the Visual Studio Properties pane, expand the Miscellaneous section and find the ItemContainerStyle property. (Make sure the ListView or GridView is selected.)

3. Click the property marker for the ItemContainerStyle property. (It's the small box next to the TextBox. It's coloreed green to show that it's set to a StaticResource.) The property menu opens.

4. In the property menu, click **Convert to New Resource**.



5. In the Create Style Resource dialog, enter a name for the resource and click OK.

A copy of the expanded template from generic.xaml is created in your app, which you can modify as needed.

Data template selection: Styling items based on their properties

Article • 06/09/2022

The customized design of collections controls are managed by a DataTemplate. Data templates define how each item should be laid out and styled, and that markup is applied to every item in the collection. This article explains how to use a DataTemplateSelector to apply different data templates on a collection and select which data template to use, based on certain item properties or values of your choosing.

> **Important APIs**: DataTemplateSelector, DataTemplate

DataTemplateSelector is a class that enables custom template selection logic. It lets you define rules that specify which data template to use for certain items in a collection. To implement this logic, you create a subclass of DataTemplateSelector in your code-behind and define the logic that determines which data template to use for which category of items (for example, items of a certain type or items with a certain property value, etc). You declare an instance of this class in the Resources section of your XAML file, along with the definitions of the data templates you'll be using. You identify these resources with an `x:Key` value, which lets you reference them in your XAML.

Prerequisites

- How to use and create a collection control, such as a ListView or GridView.
- How to customize the look of your items using a DataTemplate.

When not to use a DataTemplateSelector

Generally, you should not give every item in a ListView or GridView a completely different layout/style - this would be poor use of a DataTemplateSelector, and negatively impact performance.

Certain elements of the visual display of a list item can be controlled by using just one data template, through binding certain properties. For example, items can each have a different icon by binding to an icon source property in the data template, and giving each item a different value for that icon source property. This would achieve better performance than using a DataTemplateSelector.

When to use a DataTemplateSelector

You should create a DataTemplateSelector when you want to use multiple data templates in one collection control. A `DataTemplateSelector` gives you the flexibility to make certain items stand out, while still keeping items in a similar layout. There are many use cases in which a DataTemplateSelector is helpful, and a few scenarios in which it is better to re-think the control and strategy that you're using.

Collection controls are typically bound to a collection of items that are all of one type. However, even though items may be of the same type, they may have different values for certain properties or represent different meanings. Certain items also may be more important than others, or one item may be particularly important or different and has a need to visually stand out. In these situations, a DataTemplateSelector will be very helpful.

You can also bind to a collection that contains different types of items - the bound collection can have a mix of strings, ints, custom class objects, and more. This makes DataTemplateSelector especially useful as it can assign different data templates based on the object type of an item.

Here are some examples of when you might use a data template selector:

- Representing different levels of employees within a ListView - each type/level of employee may need a different color background to be easily distinguishable.
- Representing sale items in a product gallery that uses a GridView - a sale item may need a red background, or a different color font to make it stand out from regular-priced items.
- Representing winners/top photos in a photo gallery using FlipView.
- Needing to represent negative/positive numbers in a ListView differently, or short strings/long strings.

Create a DataTemplateSelector

When you create a data template selector, you define the template selection logic in your code, and you define the data templates in your XAML.

Code-behind component

To use a data template selector, you first create a subclass of DataTemplateSelector (a class that derives from it) in your code-behind. In your class, you declare each template

as a property of the class. Then, you override the SelectTemplateCore method to include your own template selection logic.

Here is an example of a simple `DataTemplateSelector` subclass called `MyDataTemplateSelector`.

C#

```
public class MyDataTemplateSelector : DataTemplateSelector
{
    public DataTemplate Normal { get; set; }
    public DataTemplate Accent { get; set; }

    protected override DataTemplate SelectTemplateCore(object item)
    {
        if ((int)item % 2 == 0)
        {
            return Normal;
        }
        else
        {
            return Accent;
        }
    }
}
```

The `MyDataTemplateSelector` class derives from the `DataTemplateSelector` class and first defines two DataTemplate objects: `Normal` and `Accent`. These are empty declarations for now, but will be "filled in" with markup in the XAML file.

The `SelectTemplateCore` method takes in an item object (i.e. each collection item), and is overridden with rules on which `DataTemplate` to return under which circumstances. In this case, if the item is an odd number, it receives the `Accent` data template, while if it is an even number it receives the `Normal` data template.

XAML component

Second, you must create an instance of this new `MyDataTemplateSelector` class in the Resources section of your XAML file. All resources require an `x:Key`, which you use to bind it to the `ItemTemplateSelector` property of your collection control (in a later step). You also create two instances of `DataTemplate` objects and define their layout in the resources section. You assign these data templates to the `Accent` and `Normal` properties you declared in the `MyDataTemplateSelector` class.

Here's an example of the XAML resources and markup needed:

XAML

```
<Page.Resources>

<DataTemplate x:Key="NormalItemTemplate" x:DataType="x:Int32">
    <Button HorizontalAlignment="Stretch" VerticalAlignment="Stretch"
Background="{ThemeResource SystemChromeLowColor}">
        <TextBlock Text="{x:Bind}" />
    </Button>
</DataTemplate>

<DataTemplate x:Key="AccentItemTemplate" x:DataType="x:Int32">
    <Button HorizontalAlignment="Stretch" VerticalAlignment="Stretch"
Background="{ThemeResource SystemAccentColor}">
        <TextBlock Text="{x:Bind}" />
    </Button>
</DataTemplate>

<l:MyDataTemplateSelector x:Key="MyDataTemplateSelector"
    Normal="{StaticResource NormalItemTemplate}"
    Accent="{StaticResource AccentItemTemplate}"/>

</Page.Resources>
```

As you can see above, the two data templates `Normal` and `Accent` are defined - they both display items as buttons, however the `Accent` data template uses an accent color brush for the background, while the `Normal` data template uses a gray color brush (`SystemChromeLowColor`). These two data templates are then assigned to the `Normal` and `Accent` DataTemplate objects that are attributes of the MyDataTemplateSelector class, created in the C# code-behind.

The last step is to bind your `DataTemplateSelector` to the `ItemTemplateSelector` property of your collections control (in this case, a ListView). This replaces the need for assigning a value to the `ItemTemplate` property.

XAML

```
<ListView x:Name = "TestListView"
          ItemsSource = "{x:Bind NumbersList}"
          ItemTemplateSelector = "{StaticResource MyDataTemplateSelector}">
</ListView>
```

Once your code compiles, each collection item will run through the overridden `SelectTemplateCore` method in `MyDataTemplateSelector`, and will be rendered with the appropriate DataTemplate.

> **ⓘ Important**
>
> When using `DataTemplateSelector` with an **ItemsRepeater**, you bind the `DataTemplateSelector` to the `ItemTemplate` property. `ItemsRepeater` doesn't have an `ItemTemplateSelector` property.

DataTemplateSelector performance considerations

When you use a ListView or GridView with a large data collection, scrolling and panning performance can be a concern. To keep large collections performing well, there are some steps you can take to improve the performance of your data templates. These are described in more detail in ListView and GridView UI optimization.

- *Element reduction per item* - Keep the number of UI elements in a data template to a reasonable minimum.
- Container-recycling with heterogeneous collections
  - Use *the ChoosingItemContainer event* - This event is a high-performance way to use different data templates for different items. To achieve best performance, you should optimize caching and selecting data templates for your specific data.
  - Use an *item template selector* - An item template selector (`DataTemplateSelector`) should be avoided in some instances due to its impact on performance.

Item templates for list view

Article • 06/09/2022

This section contains item templates that you can use with a **ListView** control. Use these templates to get the look of common app types.

To demonstrate data binding, these templates bind **ListViewItems** to the example Recording class from the data binding overview.

> ⓘ **Note**
>
> Currently, when a **DataTemplate** contains multiple controls (for example, more than a single **TextBlock**), the default accessible name for screenreaders comes from .ToString() on the item. As a convenience you can instead set the AutomationProperties.Name on the root element of the **DataTemplate**. For more on accessibility, see Accessibility overview.

Single line list item

Use this template to display a list of items with an image and a single line of text.

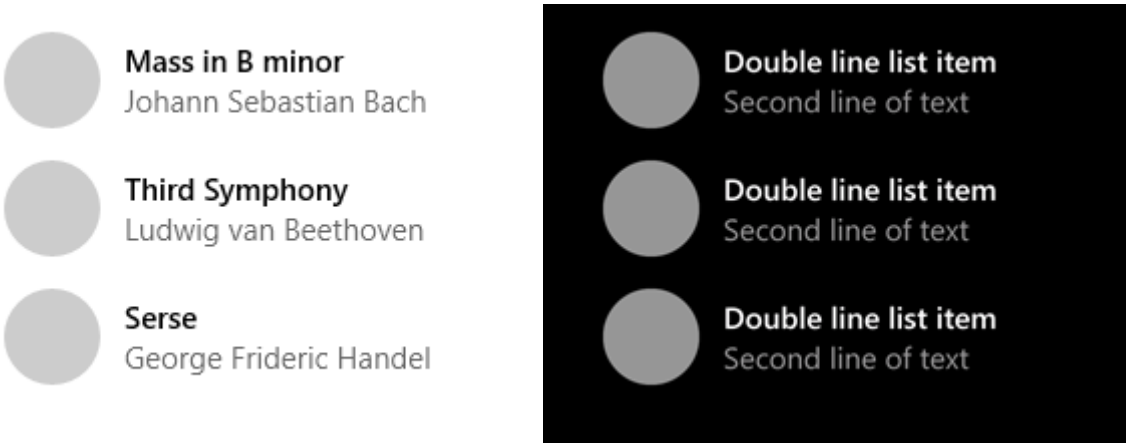
XAML

```
<ListView ItemsSource="{x:Bind ViewModel.Recordings}">
    <ListView.ItemTemplate>
        <DataTemplate x:Name="SingleLineDataTemplate"
x:DataType="local:Recording">
            <StackPanel Orientation="Horizontal" Height="44" Padding="12"
AutomationProperties.Name="{x:Bind CompositionName}">
                <Image Source="Placeholder.png" Height="16" Width="16"
VerticalAlignment="Center"/>
                <TextBlock Text="{x:Bind CompositionName}"
VerticalAlignment="Center" Style="{ThemeResource BaseTextBlockStyle}"
Foreground="{ThemeResource SystemControlPageTextBaseHighBrush}"
Margin="12,0,0,0"/>
            </StackPanel>
```

```
        </DataTemplate>
    </ListView.ItemTemplate>
</ListView>
```

Double line list item

Use this template to display a list of items with an image and two lines of text.

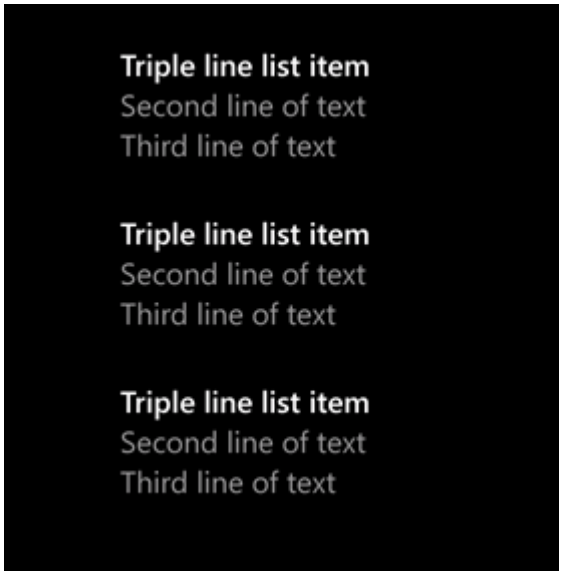


XAML

```
<ListView ItemsSource="{x:Bind ViewModel.Recordings}">
    <ListView.ItemTemplate>
        <DataTemplate x:Name="DoubleLineDataTemplate"
x:DataType="local:Recording">
            <StackPanel Orientation="Horizontal" Height="64"
AutomationProperties.Name="{x:Bind CompositionName}">
                <Ellipse Height="48" Width="48" VerticalAlignment="Center">
                    <Ellipse.Fill>
                        <ImageBrush ImageSource="Placeholder.png"/>
                    </Ellipse.Fill>
                </Ellipse>
                <StackPanel Orientation="Vertical"
VerticalAlignment="Center" Margin="12,0,0,0">
                    <TextBlock Text="{x:Bind CompositionName}"  Style="
{ThemeResource BaseTextBlockStyle}" Foreground="{ThemeResource
SystemControlPageTextBaseHighBrush}" />
                    <TextBlock Text="{x:Bind ArtistName}" Style="
{ThemeResource BodyTextBlockStyle}" Foreground="{ThemeResource
SystemControlPageTextBaseMediumBrush}"/>
                </StackPanel>
            </StackPanel>
        </DataTemplate>
    </ListView.ItemTemplate>
</ListView>
```

Triple line list item

Use this template to display a list of items with three lines of text.

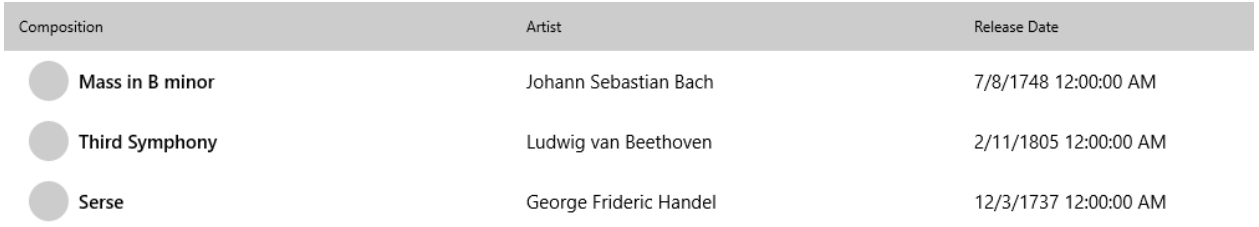


XAML

```
<ListView ItemsSource="{x:Bind ViewModel.Recordings}">
    <ListView.ItemTemplate>
        <DataTemplate x:Name="TripleLineDataTemplate"
x:DataType="local:Recording">
            <StackPanel Height="84" Padding="20" AutomationProperties.Name="
{x:Bind CompositionName}">
                <TextBlock Text="{x:Bind CompositionName}"  Style="
{ThemeResource BaseTextBlockStyle}" Margin="0,4,0,0"/>
                <TextBlock Text="{x:Bind ArtistName}" Style="{ThemeResource
CaptionTextBlockStyle}" Opacity=".8" Margin="0,4,0,0"/>
                <TextBlock Text="{x:Bind ReleaseDateTime}" Style="
{ThemeResource CaptionTextBlockStyle}" Opacity=".6" Margin="0,4,0,0"/>
            </StackPanel>
        </DataTemplate>
    </ListView.ItemTemplate>
</ListView>
```

Table list item

Use this template to display a list of items with text in defined columns.



XAML

```
<ListView  ItemsSource="{x:Bind ViewModel.Recordings}">
    <ListView.HeaderTemplate>
        <DataTemplate>
            <Grid Padding="12" Background="{ThemeResource
SystemBaseLowColor}">
                <Grid.ColumnDefinitions>
                    <ColumnDefinition Width="408"/>
                    <ColumnDefinition Width="360"/>
                    <ColumnDefinition Width="360"/>
                </Grid.ColumnDefinitions>
                <TextBlock Text="Composition" Style="{ThemeResource
CaptionTextBlockStyle}"/>
                <TextBlock Grid.Column="1" Text="Artist" Style="
{ThemeResource CaptionTextBlockStyle}"/>
                <TextBlock Grid.Column="2" Text="Release Date" Style="
{ThemeResource CaptionTextBlockStyle}"/>
            </Grid>
        </DataTemplate>
    </ListView.HeaderTemplate>
    <ListView.ItemTemplate>
        <DataTemplate x:Name="TableDataTemplate"
x:DataType="local:Recording">
            <Grid Height="48" AutomationProperties.Name="{x:Bind
CompositionName}">
                <Grid.ColumnDefinitions>
                    <ColumnDefinition Width="48"/>
                    <ColumnDefinition Width="360"/>
                    <ColumnDefinition Width="360"/>
                    <ColumnDefinition Width="360"/>
                </Grid.ColumnDefinitions>
                <Ellipse Height="32" Width="32" VerticalAlignment="Center">
                    <Ellipse.Fill>
                        <ImageBrush ImageSource="Placeholder.png"/>
                    </Ellipse.Fill>
                </Ellipse>
                <TextBlock Grid.Column="1" VerticalAlignment="Center"
Style="{ThemeResource BaseTextBlockStyle}" Text="{x:Bind CompositionName}"
/>
                <TextBlock Grid.Column="2" VerticalAlignment="Center" Text="
{x:Bind ArtistName}"/>
                <TextBlock Grid.Column="3" VerticalAlignment="Center" Text="
{x:Bind ReleaseDateTime}"/>
            </Grid>
        </DataTemplate>
    </ListView.ItemTemplate>
</ListView>
```

Item templates for grid view

Article • 06/09/2022

This section contains item templates that you can use with a **GridView** control. Use these templates to get the look of common app types.

To demonstrate data binding, these templates bind **GridViewItems** to the example Recording class from the data binding overview.

> **Note**
>
> Currently, when a **DataTemplate** contains multiple controls (for example, more than a single **TextBlock**), the default accessible name for screenreaders comes from .ToString() on the item. As a convenience you can instead set the AutomationProperties.Name on the root element of the **DataTemplate**. For more on accessibility, see Accessibility overview.

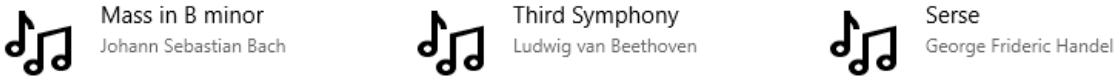
Icon and text

Use these templates to display a collection of apps in a grid with an icon and text.

XAML

```
<GridView ItemsSource="{x:Bind ViewModel.Recordings}">
    <GridView.ItemTemplate>
        <DataTemplate x:Name="IconTextTemplate"
x:DataType="local:Recording">
            <StackPanel Width="264" Height="48" Padding="12"
Orientation="Horizontal" AutomationProperties.Name="{x:Bind
CompositionName}">
                <SymbolIcon Symbol="Audio" VerticalAlignment="Top"/>
                <TextBlock Margin="12,0,0,0" Width="204" Text="{x:Bind
CompositionName}"/>
            </StackPanel>
        </DataTemplate>
    </GridView.ItemTemplate>
    <GridView.ItemsPanel>
        <ItemsPanelTemplate>
            <ItemsWrapGrid MaximumRowsOrColumns="4" Orientation="Horizontal"
HorizontalAlignment="Center"/>
        </ItemsPanelTemplate>
```

```
    </GridView.ItemsPanel>
</GridView>
```

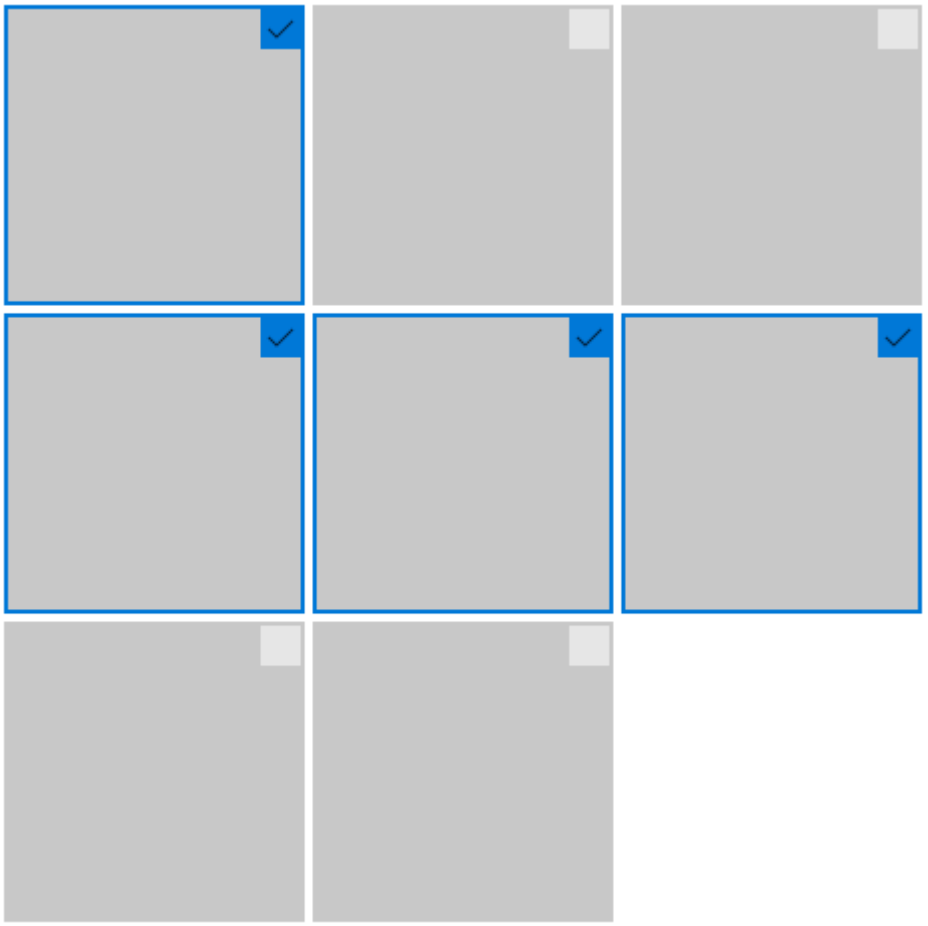


XAML

```
<GridView ItemsSource="{x:Bind ViewModel.Recordings}">
    <GridView.ItemTemplate>
        <DataTemplate x:Name="IconTextTemplate2"
x:DataType="local:Recording">
            <StackPanel Width="264" Height="120" Padding="12"
Orientation="Horizontal" AutomationProperties.Name="{x:Bind
CompositionName}">
                <FontIcon Margin="0,6,0,0" FontSize="48" FontFamily="Segoe
MDL2 Assets" FontWeight="Bold" Glyph="&#xE8D6;" VerticalAlignment="Top"/>
                <StackPanel Margin="16,1,0,0">
                    <TextBlock Width="176" Margin="0,0,0,2"
TextWrapping="WrapWholeWords" TextTrimming="Clip" Text="{x:Bind
CompositionName}"/>
                    <TextBlock Width="176" Height="48" Style="{ThemeResource
CaptionTextBlockStyle}" Foreground="{ThemeResource
SystemControlPageTextBaseMediumBrush}" TextWrapping="WrapWholeWords"
TextTrimming="Clip" Text="{x:Bind ArtistName}" />
                </StackPanel>
            </StackPanel>
        </DataTemplate>
    </GridView.ItemTemplate>
    <GridView.ItemsPanel>
        <ItemsPanelTemplate>
            <ItemsWrapGrid MaximumRowsOrColumns="4" Orientation="Horizontal"
HorizontalAlignment="Center" Margin="40,0"/>
        </ItemsPanelTemplate>
    </GridView.ItemsPanel>
</GridView>
```

Image gallery

Use this template to display a collection of images in a grid with multi-select mode.

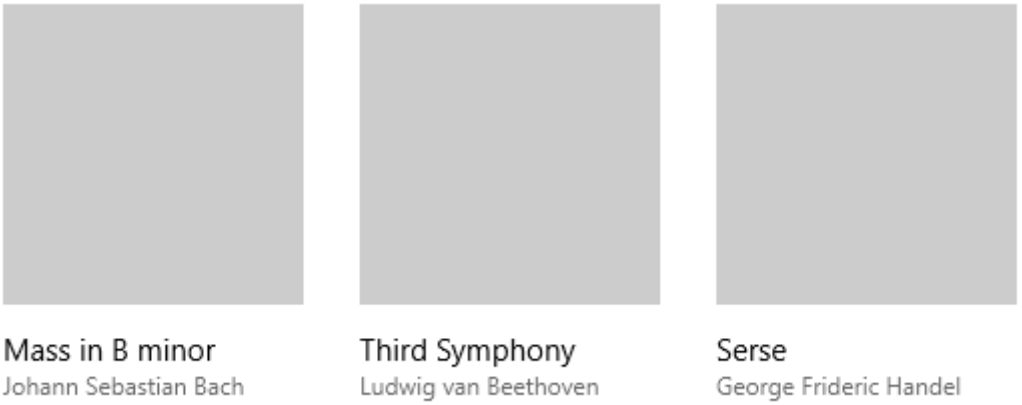


XAML

```
<GridView SelectionMode="Multiple">
    <GridView.ItemTemplate>
        <DataTemplate x:Name="ImageGalleryDataTemplate">
            <Image Source="Placeholder.png" Height="180" Width="180"
Stretch="UniformToFill"/>
        </DataTemplate>
    </GridView.ItemTemplate>
    <GridView.ItemsPanel>
        <ItemsPanelTemplate>
            <ItemsWrapGrid MaximumRowsOrColumns="3"
Orientation="Horizontal"/>
        </ItemsPanelTemplate>
    </GridView.ItemsPanel>
</GridView>
```

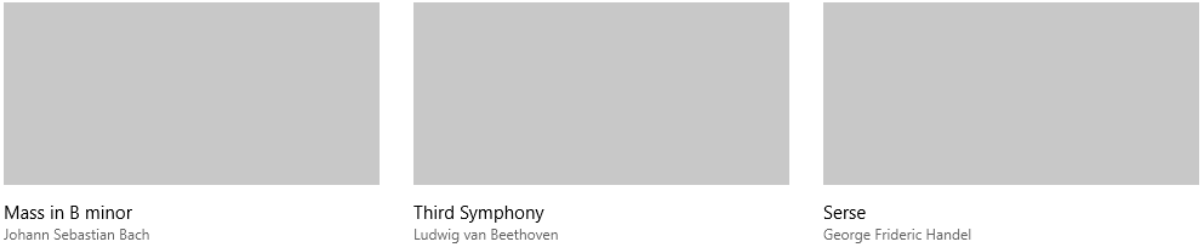
Image and text

Use these templates to display a media collection with text underneath.



XAML

```
<GridView ItemsSource="{x:Bind ViewModel.Recordings}">
    <GridView.ItemTemplate>
        <DataTemplate x:Name="ImageTextDataTemplate"
x:DataType="local:Recording">
            <StackPanel Height="280" Width="180" Margin="12"
AutomationProperties.Name="{x:Bind CompositionName}">
                <Image Source="Placeholder.png" Height="180" Width="180"
Stretch="UniformToFill"/>
                <StackPanel Margin="0,12">
                    <TextBlock Text="{x:Bind CompositionName}"/>
                    <TextBlock Text="{x:Bind ArtistName}" Style="
{ThemeResource CaptionTextBlockStyle}" Foreground="{ThemeResource
SystemControlPageTextBaseMediumBrush}"/>
                </StackPanel>
            </StackPanel>
        </DataTemplate>
    </GridView.ItemTemplate>
    <GridView.ItemsPanel>
        <ItemsPanelTemplate>
            <ItemsWrapGrid MaximumRowsOrColumns="10"
Orientation="Horizontal"/>
        </ItemsPanelTemplate>
    </GridView.ItemsPanel>
</GridView>
```

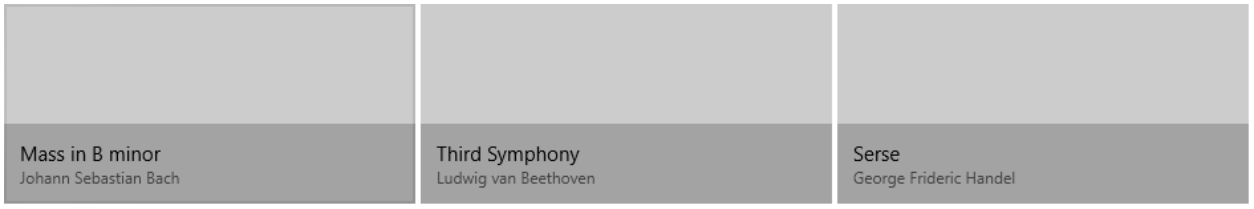


XAML

```
<GridView ItemsSource="{x:Bind ViewModel.Recordings}">
    <GridView.ItemTemplate>
        <DataTemplate x:Name="ImageTextDataTemplate2"
x:DataType="local:Recording">
            <StackPanel Height="280" Width="320" Margin="12"
AutomationProperties.Name="{x:Bind CompositionName}">
                <Image Source="Placeholder.png" Height="180" Width="320"
Stretch="UniformToFill"/>
                <StackPanel Margin="0,12">
                    <TextBlock Text="{x:Bind CompositionName}"/>
                    <TextBlock Text="{x:Bind ArtistName}" Style="
{ThemeResource CaptionTextBlockStyle}" Foreground="{ThemeResource
SystemControlPageTextBaseMediumBrush}"/>
                </StackPanel>
            </StackPanel>
        </DataTemplate>
    </GridView.ItemTemplate>
    <GridView.ItemsPanel>
        <ItemsPanelTemplate>
            <ItemsWrapGrid MaximumRowsOrColumns="4"
Orientation="Horizontal"/>
        </ItemsPanelTemplate>
    </GridView.ItemsPanel>
</GridView>
```

Image with text overlay

Use this template to display a media collection with text overlay.



XAML

```
<GridView ItemsSource="{x:Bind ViewModel.Recordings}">
    <GridView.ItemTemplate>
        <DataTemplate x:Name="ImageOverlayDataTemplate"
x:DataType="local:Recording">
            <Grid Height="180" Width="320" AutomationProperties.Name="
{x:Bind CompositionName}">
                <Image Source="Placeholder.png" Stretch="UniformToFill"/>
                <StackPanel Orientation="Vertical" Height="60"
VerticalAlignment="Bottom" Background="{ThemeResource SystemBaseLowColor}"
Padding="12">
                    <TextBlock Text="{x:Bind CompositionName}"/>
                    <TextBlock Text="{x:Bind ArtistName}" Style="
{ThemeResource CaptionTextBlockStyle}" Foreground="{ThemeResource
```

```
SystemControlPageTextBaseMediumBrush}"/>
                </StackPanel>
            </Grid>
        </DataTemplate>
    </GridView.ItemTemplate>
    <GridView.ItemsPanel>
        <ItemsPanelTemplate>
            <ItemsWrapGrid MaximumRowsOrColumns="4"
Orientation="Horizontal"/>
        </ItemsPanelTemplate>
    </GridView.ItemsPanel>
</GridView>
```

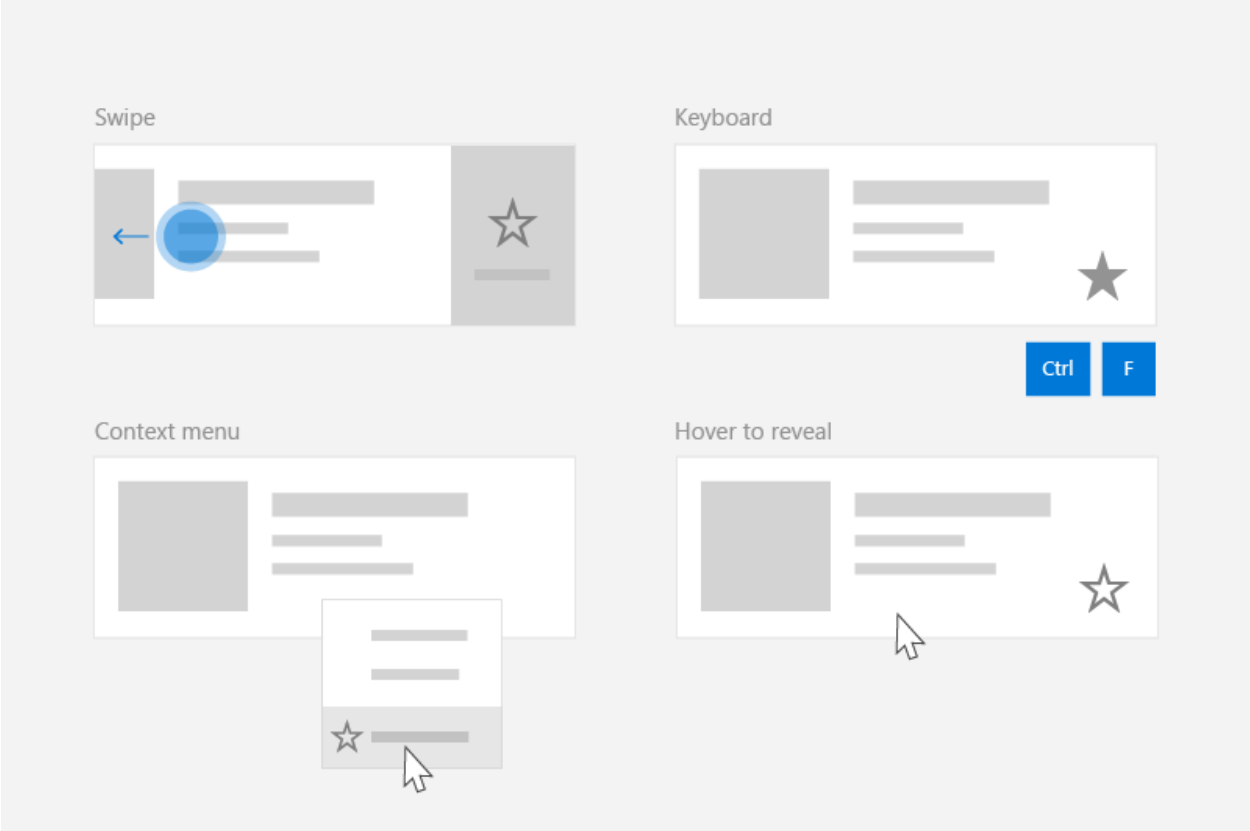
Contextual commanding for collections and lists

Article • 06/09/2022

Many apps contain collections of content in the form of lists, grids, and trees that users can manipulate. For example, users might be able to delete, rename, flag, or refresh items. This article shows you how to use contextual commands to implement these sorts of actions in a way that provides the best possible experience for all input types.

> **Important APIs**: ICommand interface, UIElement.ContextFlyout property, INotifyPropertyChanged interface



Creating commands for all input types

Because users can interact with a Windows app using a broad range of devices and inputs, your app should expose commands though both input-agnostic context menus and input-specific accelerators. Including both lets the user quickly invoke commands on content, regardless of input or device type.

This table shows some typical collection commands and ways to expose those commands.

Command	Input-agnostic	Mouse accelerator	Keyboard accelerator	Touch accelerator
Delete item	Context menu	Hover button	DEL key	Swipe to delete
Flag item	Context menu	Hover button	Ctrl+Shift+G	Swipe to flag
Refresh data	Context menu	N/A	F5 key	Pull to refresh
Favorite an item	Context menu	Hover button	F, Ctrl+S	Swipe to favorite

- **In general, you should make all commands for an item available in the item's context menu.** Context menus are accessible to users regardless of input type, and should contain all of the contextual commands that user can perform.
- **For frequently accessed commands, consider using input accelerators.** Input accelerators let the user perform actions quickly, based on their input device. Input accelerators include:
  - Swipe-to-action (touch accelerator)
  - Pull to refresh data (touch accelerator)
  - Keyboard shortcuts (keyboard accelerator)
  - Access keys (keyboard accelerator)
  - Mouse & Pen hover buttons (pointer accelerator)

> ⓘ Note
>
> Users should be able to access all commands from any type of device. For example, if your app's commands are only exposed through hover button pointer accelerators, touch users won't be able to access them. At a minimum, use a context menu to provide access to all commands.

Example: The PodcastObject data model

To demonstrate our commanding recommendations, this article creates a list of podcasts for a podcast app. The example code demonstrate how to enable the user to "favorite" a particular podcast from a list.

Here's the definition for the podcast object we'll be working with:

```
C#

public class PodcastObject : INotifyPropertyChanged
{
```

```
    // The title of the podcast
    public String Title { get; set; }

    // The podcast's description
    public String Description { get; set; }

    // Describes if the user has set this podcast as a favorite
    public bool IsFavorite
    {
        get
        {
            return _isFavorite;
        }
        set
        {
            _isFavorite = value;
            OnPropertyChanged("IsFavorite");
        }
    }
    private bool _isFavorite = false;

    public event PropertyChangedEventHandler PropertyChanged;

    private void OnPropertyChanged(String property)
    {
        PropertyChanged?.Invoke(this, new
PropertyChangedEventArgs(property));
    }
}
```

Notice that the PodcastObject implements INotifyPropertyChanged to respond to property changes when the user toggles the IsFavorite property.

Defining commands with the ICommand interface

The ICommand interface helps you to define a command that's available for multiple input types. For example, instead of writing the same code for a delete command in two different event handlers, one for when the user presses the Delete key and one for when the user right clicks "Delete" in a context menu, you can implement your delete logic once, as an ICommand, and then make it available to different input types.

We need to define the ICommand that represents the "Favorite" action. We will use the command's Execute method to favorite a podcast. The particular podcast will be provided to the execute method via the command's parameter, which can be bound using the CommandParameter property.

C#

```
public class FavoriteCommand: ICommand
{
    public event EventHandler CanExecuteChanged;

    public bool CanExecute(object parameter)
    {
        return true;
    }
    public void Execute(object parameter)
    {
        // Perform the logic to "favorite" an item.
        (parameter as PodcastObject).IsFavorite = true;
    }
}
```

To use the same command with multiple collections and elements, you can store the command as a resource on the page or on the app.

XAML

```
<Application.Resources>
    <local:FavoriteCommand x:Key="favoriteCommand" />
</Application.Resources>
```

To execute the command, you call its Execute method.

C#

```
// Favorite the item using the defined command
var favoriteCommand = Application.Current.Resources["favoriteCommand"] as
ICommand;
favoriteCommand.Execute(PodcastObject);
```

Creating a UserControl to respond to a variety of inputs

When you have a list of items and each of those items should respond to multiple inputs, you can simplify your code by defining a UserControl for the item and using it to define your items' context menu and event handlers.

To create a UserControl in Visual Studio:

1. In the Solution Explorer, right click the project. A context menu appears.

2. Select **Add** > **New Item...**
   The **Add New Item** dialog appears.
3. Select UserControl from the list of items. Give it the name you want and click **Add**.
   Visual Studio will generate a stub UserControl for you.

In our podcast example, each podcast will be displayed in a list, which will expose a variety of ways to "Favorite" a podcast. The user will be able to perform the following actions to "Favorite" the podcast:

- Invoke a context menu
- Perform keyboard shortcuts
- Show a hover button
- Perform a swipe gesture

In order to encapsulate these behaviors and use the FavoriteCommand, let's create a new UserControl named "PodcastUserControl" to represent a podcast in the list.

The PodcastUserControl displays the fields of the PodcastObject as TextBlocks, and responds to various user interactions. We will reference and expand upon the PodcastUserControl throughout this article.

PodcastUserControl.xaml

XAML

```
<UserControl
    x:Class="ContextCommanding.PodcastUserControl"
    xmlns="http://schemas.microsoft.com/winfx/2006/xaml/presentation"
    xmlns:x="http://schemas.microsoft.com/winfx/2006/xaml"
    xmlns:d="http://schemas.microsoft.com/expression/blend/2008"
    xmlns:mc="http://schemas.openxmlformats.org/markup-compatibility/2006"
    mc:Ignorable="d"
    IsTabStop="True" UseSystemFocusVisuals="True"
    >
    <Grid Margin="12,0,12,0">
        <StackPanel>
            <TextBlock Text="{x:Bind PodcastObject.Title, Mode=OneWay}"
Style="{StaticResource TitleTextBlockStyle}" />
            <TextBlock Text="{x:Bind PodcastObject.Description,
Mode=OneWay}" Style="{StaticResource SubtitleTextBlockStyle}" />
            <TextBlock Text="{x:Bind PodcastObject.IsFavorite, Mode=OneWay}"
Style="{StaticResource SubtitleTextBlockStyle}"/>
        </StackPanel>
    </Grid>
</UserControl>
```

PodcastUserControl.xaml.cs

C#

```
public sealed partial class PodcastUserControl : UserControl
{
    public static readonly DependencyProperty PodcastObjectProperty =
        DependencyProperty.Register(
            "PodcastObject",
            typeof(PodcastObject),
            typeof(PodcastUserControl),
            new PropertyMetadata(null));

    public PodcastObject PodcastObject
    {
        get { return (PodcastObject)GetValue(PodcastObjectProperty); }
        set { SetValue(PodcastObjectProperty, value); }
    }

    public PodcastUserControl()
    {
        this.InitializeComponent();

        // TODO: We will add event handlers here.
    }
}
```

Notice that the PodcastUserControl maintains a reference to the PodcastObject as a DependencyProperty. This enables us to bind PodcastObjects to the PodcastUserControl.

After you have generated some PodcastObjects, you can create a list of podcasts by binding the PodcastObjects to a ListView. The PodcastUserControl objects describe the visualization of the PodcastObjects, and are therefore set using the ListView's ItemTemplate.

MainPage.xaml

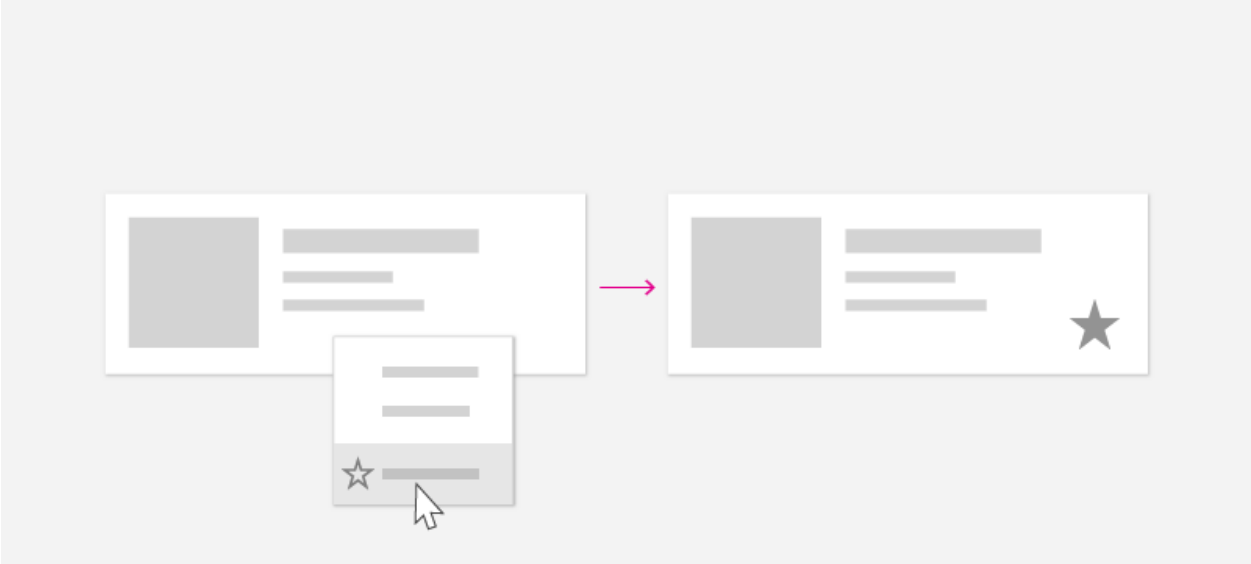
XAML

```
<ListView x:Name="ListOfPodcasts"
            ItemsSource="{x:Bind podcasts}">
    <ListView.ItemTemplate>
        <DataTemplate x:DataType="local:PodcastObject">
            <local:PodcastUserControl PodcastObject="{x:Bind Mode=OneWay}"
/>
        </DataTemplate>
    </ListView.ItemTemplate>
    <ListView.ItemContainerStyle>
        <!-- The PodcastUserControl will entirely fill the ListView item and
handle tabbing within itself. -->
        <Style TargetType="ListViewItem" BasedOn="{StaticResource
```

```
ListViewItemRevealStyle}">
            <Setter Property="HorizontalContentAlignment" Value="Stretch" />
            <Setter Property="Padding" Value="0"/>
            <Setter Property="IsTabStop" Value="False"/>
        </Style>
    </ListView.ItemContainerStyle>
</ListView>
```

Creating context menus

Context menus display a list of commands or options when the user requests them. Context menus provide contextual commands related to their attached element, and are generally reserved for secondary actions specific to that item.



The user can invoke context menus using these "context actions":

Input	Context action
Mouse	Right click
Keyboard	Shift+F10, Menu button
Touch	Long press on item
Pen	Barrel button press, long press on item
Gamepad	Menu button

Since the user can open a context menu regardless of input type, your context menu should contain all of the contextual commands available for the list item.

ContextFlyout

The ContextFlyout property, defined by the UIElement class, makes it easy to create a context menu that works with all input types. You provide a flyout representing your context menu using MenuFlyout or CommandBarFlyout, and when the user performs a "context action" as defined above, the MenuFlyout or CommandBarFlyout corresponding to the item will be displayed.

See menus and context menus for help identifying menu vs. context menu scenarios and guidance on when to use menu flyout vs. command bar flyout.

For this example, we will use MenuFlyout and will start by adding a ContextFlyout to the PodcastUserControl. The MenuFlyout specified as the ContextFlyout contains a single item to favorite a podcast. Notice that this MenuFlyoutItem uses the favoriteCommand defined above, with the CommandParameter bound to the PodcastObject.

PodcastUserControl.xaml

XAML

```
<UserControl>
    <UserControl.ContextFlyout>
        <MenuFlyout>
            <MenuFlyoutItem Text="Favorite" Command="{StaticResource
favoriteCommand}" CommandParameter="{x:Bind PodcastObject, Mode=OneWay}" />
        </MenuFlyout>
    </UserControl.ContextFlyout>
    <Grid Margin="12,0,12,0">
        <!-- ... -->
    </Grid>
</UserControl>
```

Note that you can also use the ContextRequested event to respond to context actions. The ContextRequested event will not fire if a ContextFlyout has been specified.

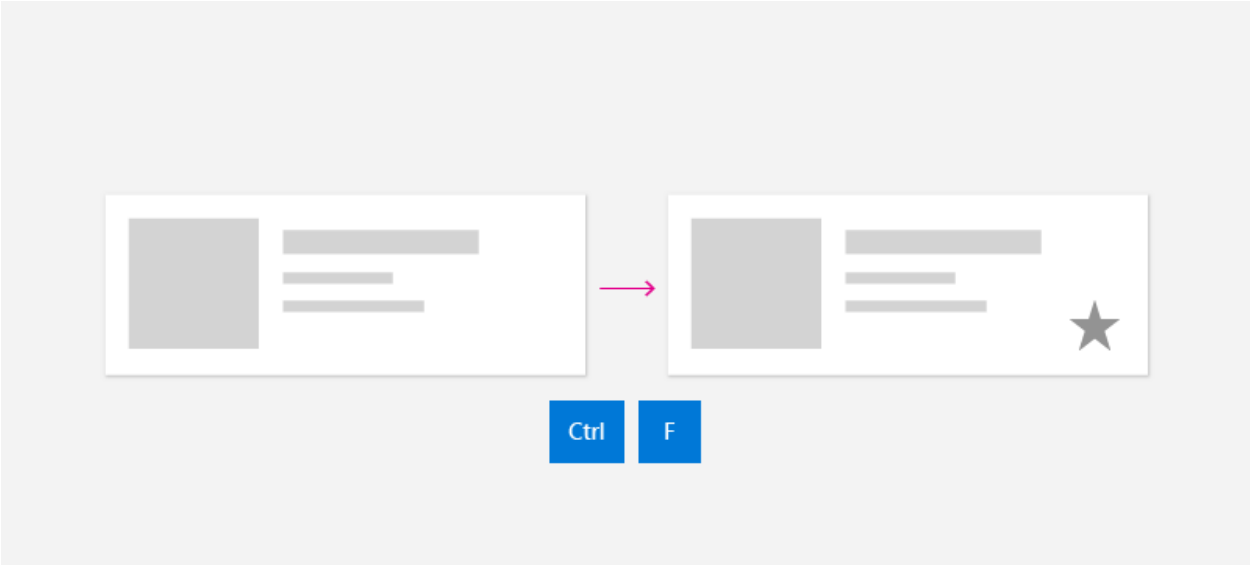
Creating input accelerators

Although each item in the collection should have a context menu containing all contextual commands, you might want to enable users to quickly perform a smaller set of frequently performed commands. For example, a mailing app may have secondary commands like Reply, Archive, Move to Folder, Set Flag, and Delete which appear in a context menu, but the most common commands are Delete and Flag. After you have identified which commands are most common, you can use input-based accelerators to make these commands easier for a user to perform.

In the podcast app, the frequently performed command is the "Favorite" command.

Keyboard accelerators

Shortcuts and direct key handling



Depending on the type of content, you may identify certain key combinations that should perform an action. In an email app, for example, the DEL key may be used to delete the email that is selected. In a podcast app, the Ctrl+S or F keys could favorite a podcast for later. Although some commands have common, well-known keyboard shortcuts like DEL to delete, other commands have app- or domain-specific shortcuts. Use well-known shortcuts if possible, or consider providing reminder text in a tooltip to teach the user about the shortcut command.

Your app can respond when the user presses a key using the KeyDown event. In general, users expect that the app will respond when they first press the key down, rather than waiting until they release the key.

This example walks through how to add the KeyDown handler to the PodcastUserControl to favorite a podcast when the user presses Ctrl+S or F. It uses the same command as before.

PodcastUserControl.xaml.cs

C#

```
// Respond to the F and Ctrl+S keys to favorite the focused item.
protected override void OnKeyDown(KeyRoutedEventArgs e)
{
    var ctrlState =
CoreWindow.GetForCurrentThread().GetKeyState(VirtualKey.Control);
    var isCtrlPressed = (ctrlState & CoreVirtualKeyStates.Down) ==
CoreVirtualKeyStates.Down || (ctrlState & CoreVirtualKeyStates.Locked) ==
CoreVirtualKeyStates.Locked;
```

```
    if (e.Key == Windows.System.VirtualKey.F || (e.Key ==
Windows.System.VirtualKey.S && isCtrlPressed))
    {
        // Favorite the item using the defined command
        var favoriteCommand =
Application.Current.Resources["favoriteCommand"] as ICommand;
        favoriteCommand.Execute(PodcastObject);
    }
}
```

Mouse accelerators

Users are familiar with right-click context menus, but you may wish to empower users to perform common commands using only a single click of the mouse. To enable this experience, you can include dedicated buttons on your collection item's canvas. To both empower users to act quickly using mouse, and to minimize visual clutter, you can choose to only reveal these buttons when the user has their pointer within a particular list item.

In this example, the Favorite command is represented by a button defined directly in the PodcastUserControl. Note that the button in this example uses the same command, FavoriteCommand, as before. To toggle visibility of this button, you can use the VisualStateManager to switch between visual states when the pointer enters and exits the control.

PodcastUserControl.xaml

XAML

```
<UserControl>
    <UserControl.ContextFlyout>
```

```
        <!-- ... -->
    </UserControl.ContextFlyout>
    <Grid Margin="12,0,12,0">
        <VisualStateManager.VisualStateGroups>
            <VisualStateGroup x:Name="HoveringStates">
                <VisualState x:Name="HoverButtonsShown">
                    <VisualState.Setters>
                        <Setter Target="hoverArea.Visibility"
Value="Visible" />
                    </VisualState.Setters>
                </VisualState>
                <VisualState x:Name="HoverButtonsHidden" />
            </VisualStateGroup>
        </VisualStateManager.VisualStateGroups>
        <Grid.ColumnDefinitions>
            <ColumnDefinition Width="*" />
            <ColumnDefinition Width="Auto" />
        </Grid.ColumnDefinitions>
        <StackPanel>
            <TextBlock Text="{x:Bind PodcastObject.Title, Mode=OneWay}"
Style="{StaticResource TitleTextBlockStyle}" />
            <TextBlock Text="{x:Bind PodcastObject.Description,
Mode=OneWay}" Style="{StaticResource SubtitleTextBlockStyle}" />
            <TextBlock Text="{x:Bind PodcastObject.IsFavorite, Mode=OneWay}"
Style="{StaticResource SubtitleTextBlockStyle}"/>
        </StackPanel>
        <Grid Grid.Column="1" x:Name="hoverArea" Visibility="Collapsed"
VerticalAlignment="Stretch">
            <AppBarButton Icon="OutlineStar" Label="Favorite" Command="
{StaticResource favoriteCommand}" CommandParameter="{x:Bind PodcastObject,
Mode=OneWay}" IsTabStop="False" VerticalAlignment="Stretch"  />
        </Grid>
    </Grid>
</UserControl>
```

The hover buttons should appear and disappear when the mouse enters and exits the item. To respond to mouse events, you can use the PointerEntered and PointerExited events on the PodcastUserControl.

PodcastUserControl.xaml.cs

C#

```
protected override void OnPointerEntered(PointerRoutedEventArgs e)
{
    base.OnPointerEntered(e);

    // Only show hover buttons when the user is using mouse or pen.
    if (e.Pointer.PointerDeviceType ==
Windows.Devices.Input.PointerDeviceType.Mouse || e.Pointer.PointerDeviceType
== Windows.Devices.Input.PointerDeviceType.Pen)
    {
```

```
            VisualStateManager.GoToState(this, "HoverButtonsShown", true);
        }
    }

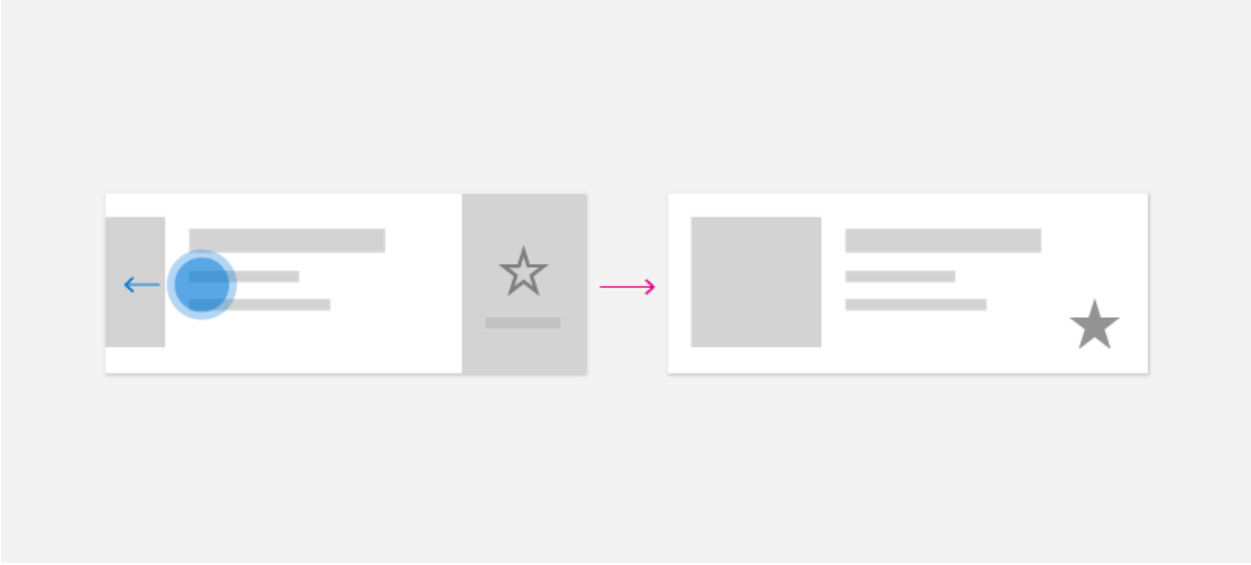
    protected override void OnPointerExited(PointerRoutedEventArgs e)
    {
        base.OnPointerExited(e);

        VisualStateManager.GoToState(this, "HoverButtonsHidden", true);
    }
```

The buttons displayed in the hover state will only be accessible via the pointer input type. Because these buttons are limited to pointer input, you may choose to minimize or remove the padding around the icon of the button to optimize for pointer input. If you choose to do so, ensure that the button footprint is at least 20x20px to remain usable with pen and mouse.

Touch accelerators

Swipe



Swipe commanding is a touch accelerator that enables users on touch devices to perform common secondary actions using touch. Swipe empowers touch users to quickly and naturally interact with content, using common actions like Swipe-to-Delete or Swipe-to-Invoke. See the swipe commanding article to learn more.

In order to integrate swipe into your collection, you need two components: SwipeItems, which hosts the commands; and a SwipeControl, which wraps the item and allows for swipe interaction.

The SwipeItems can be defined as a Resource in the PodcastUserControl. In this example, SwipeItems contains a command to Favorite an item.

XAML

```
<UserControl.Resources>
    <SymbolIconSource x:Key="FavoriteIcon" Symbol="Favorite"/>
    <SwipeItems x:Key="RevealOtherCommands" Mode="Reveal">
        <SwipeItem IconSource="{StaticResource FavoriteIcon}"
Text="Favorite" Background="Yellow" Invoked="SwipeItem_Invoked"/>
    </SwipeItems>
</UserControl.Resources>
```

The SwipeControl wraps the item and allows the user to interact with it using the swipe gesture. Notice that the SwipeControl contains a reference to the SwipeItems as its RightItems. The Favorite item will show when the user swipes from right to left.

XAML

```
<SwipeControl x:Name="swipeContainer" RightItems="{StaticResource
RevealOtherCommands}">
   <!-- The visual state groups moved from the Grid to the SwipeControl,
since the SwipeControl wraps the Grid. -->
   <VisualStateManager.VisualStateGroups>
       <VisualStateGroup x:Name="HoveringStates">
           <VisualState x:Name="HoverButtonsShown">
               <VisualState.Setters>
                   <Setter Target="hoverArea.Visibility" Value="Visible" />
               </VisualState.Setters>
           </VisualState>
           <VisualState x:Name="HoverButtonsHidden" />
       </VisualStateGroup>
   </VisualStateManager.VisualStateGroups>
   <Grid Margin="12,0,12,0">
       <Grid.ColumnDefinitions>
           <ColumnDefinition Width="*" />
           <ColumnDefinition Width="Auto" />
       </Grid.ColumnDefinitions>
       <StackPanel>
           <TextBlock Text="{x:Bind PodcastObject.Title, Mode=OneWay}"
Style="{StaticResource TitleTextBlockStyle}" />
           <TextBlock Text="{x:Bind PodcastObject.Description, Mode=OneWay}"
Style="{StaticResource SubtitleTextBlockStyle}" />
           <TextBlock Text="{x:Bind PodcastObject.IsFavorite, Mode=OneWay}"
Style="{StaticResource SubtitleTextBlockStyle}"/>
       </StackPanel>
       <Grid Grid.Column="1" x:Name="hoverArea" Visibility="Collapsed"
VerticalAlignment="Stretch">
           <AppBarButton Icon="OutlineStar" Command="{StaticResource
favoriteCommand}" CommandParameter="{x:Bind PodcastObject, Mode=OneWay}"
IsTabStop="False" LabelPosition="Collapsed" VerticalAlignment="Stretch"  />
```

```
        </Grid>
    </Grid>
</SwipeControl>
```

When the user swipes to invoke the Favorite command, the Invoked method is called.

C#

```
private void SwipeItem_Invoked(SwipeItem sender, SwipeItemInvokedEventArgs
args)
{
    // Favorite the item using the defined command
    var favoriteCommand = Application.Current.Resources["favoriteCommand"]
as ICommand;
    favoriteCommand.Execute(PodcastObject);
}
```

Pull to refresh

Pull to refresh lets a user pull down on a collection of data using touch in order to retrieve more data. See the pull to refresh article to learn more.

Pen accelerators

The pen input type provides the precision of pointer input. Users can perform common actions such as opening context menus using pen-based accelerators. To open a context menu, users can tap the screen with the barrel button pressed, or long press on the content. Users can also use the pen to hover over content to get a deeper understanding of the UI like displaying tooltips, or to reveal secondary hover actions, similar to mouse.

To optimize your app for pen input, see the pen and stylus interaction article.

Recommendations

- Make sure that users can access all commands from all types of Windows devices.
- Include a context menu that provides access to all the commands available for a collection item.
- Provide input accelerators for frequently-used commands.
- Use the ICommand interface to implement commands.

Selection mode overview

Article • 06/24/2021

Selection mode lets users select and take action on a single item or on multiple items. It can be invoked through a context menu, by using CTRL+click or SHIFT+click on an item, or by rolling-over a target on an item in a gallery view. When selection mode is active, check boxes appear next to each list item, and actions can appear at the top or the bottom of the screen.

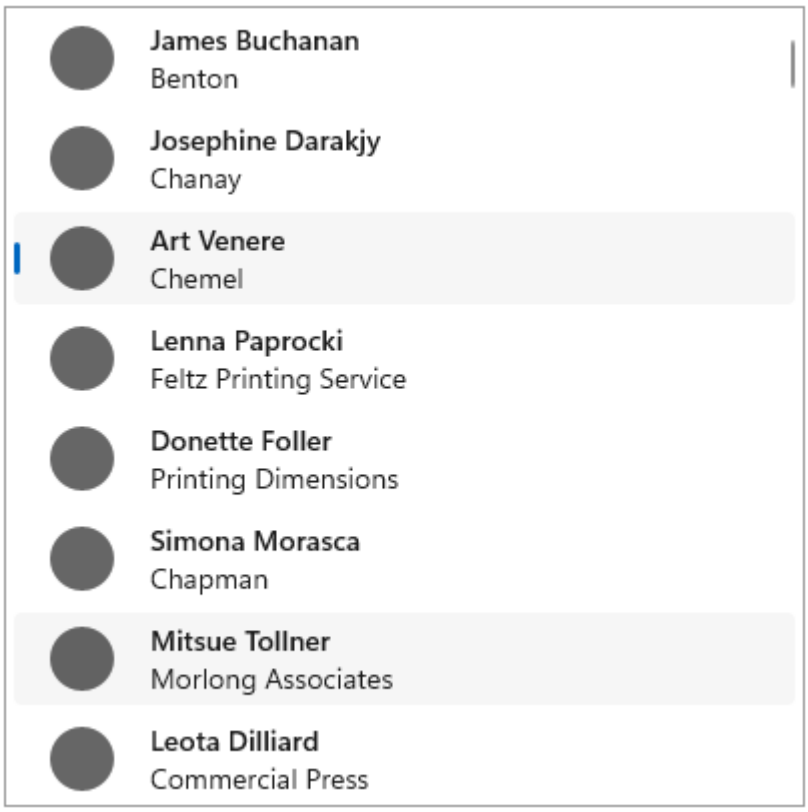
Different selection modes

There are three selection modes:

- Single: The user can select only one item at a time.
- Multiple: The user can select multiple items without using a modifier.
- Extended: The user can select multiple items with a modifier, such as holding down the SHIFT key.

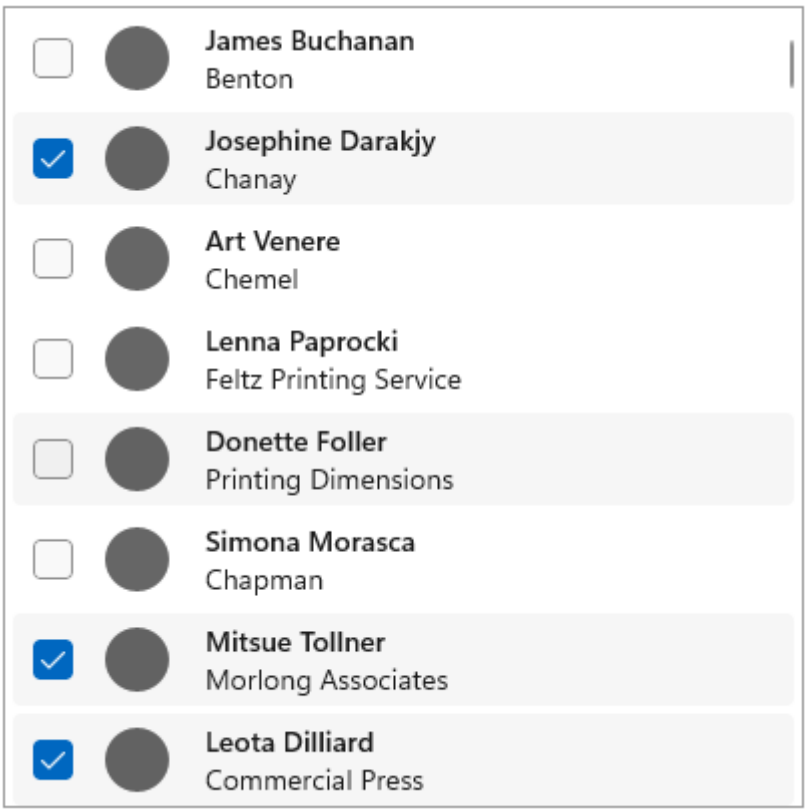
Selection mode examples

Here is a ListView with single selection mode enabled.



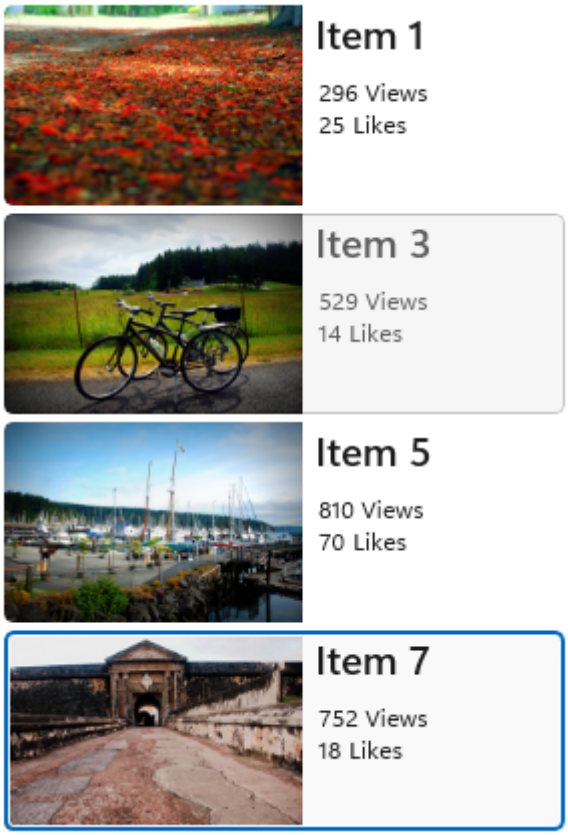
The item Art Venere is selected, and the item Mitsue Tollner is currently being hovered over.

Here is a ListView with multiple selection mode enabled:



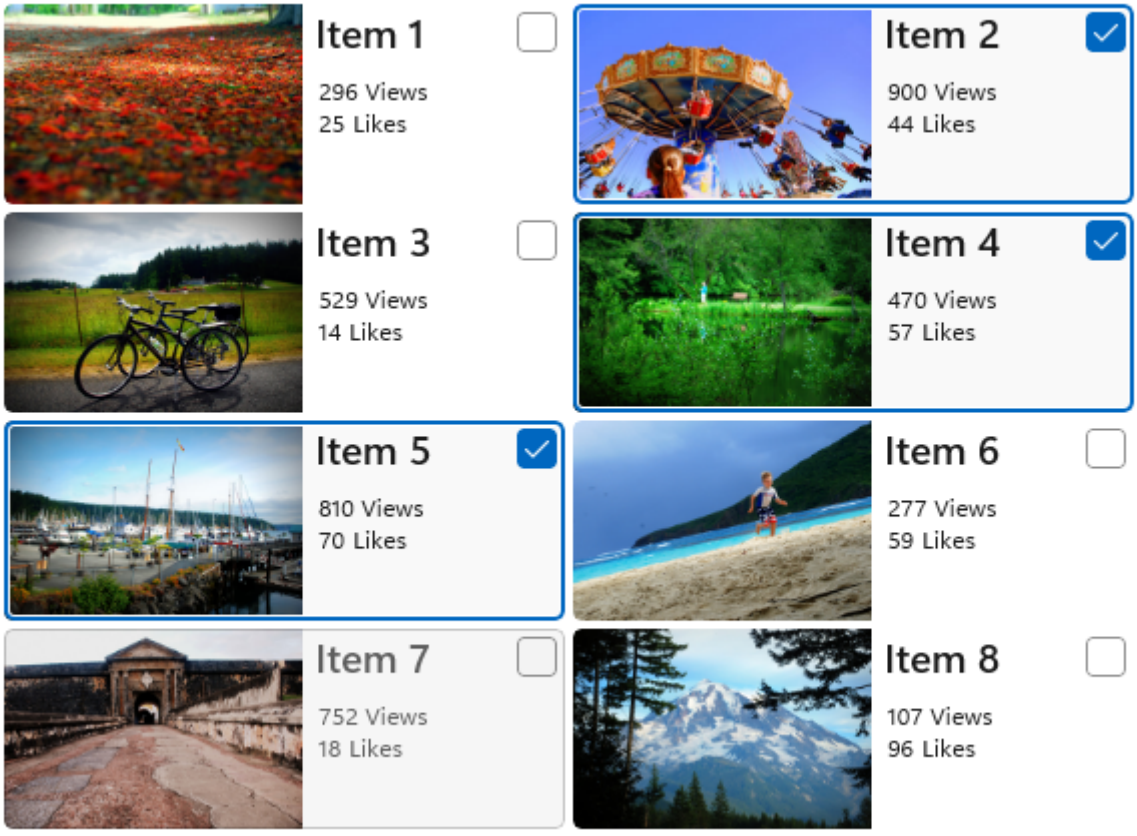
There are three items selected, and the item Donette Foller is being hovered over.

Here is a GridView with single selection mode enabled:



Item 7 is selected, and Item 3 is currently being hovered over.

Here is a GridView with multiple selection mode enabled:



Items 2, 4, and 5 are selected, and Item 7 is currently being hovered over.

Behavior and interaction

Tapping anywhere on an item selects it. Tapping on the command bar action affects all selected items. If no item is selected, command bar actions should be inactive, except for "Select All".

Selection mode doesn't have a light dismiss model; tapping outside of the frame in which selection mode is active won't cancel the mode. This is to prevent accidental deactivation of the mode. Clicking the back button dismisses the multi-select mode.

Show a visual confirmation when an action is selected. Consider displaying a confirmation dialog for certain actions, especially destructive actions such as delete.

Selection mode is confined to the page in which it is active, and can't affect any items outside of that page.

The entry point to selection mode should be juxtaposed against the content it affects.

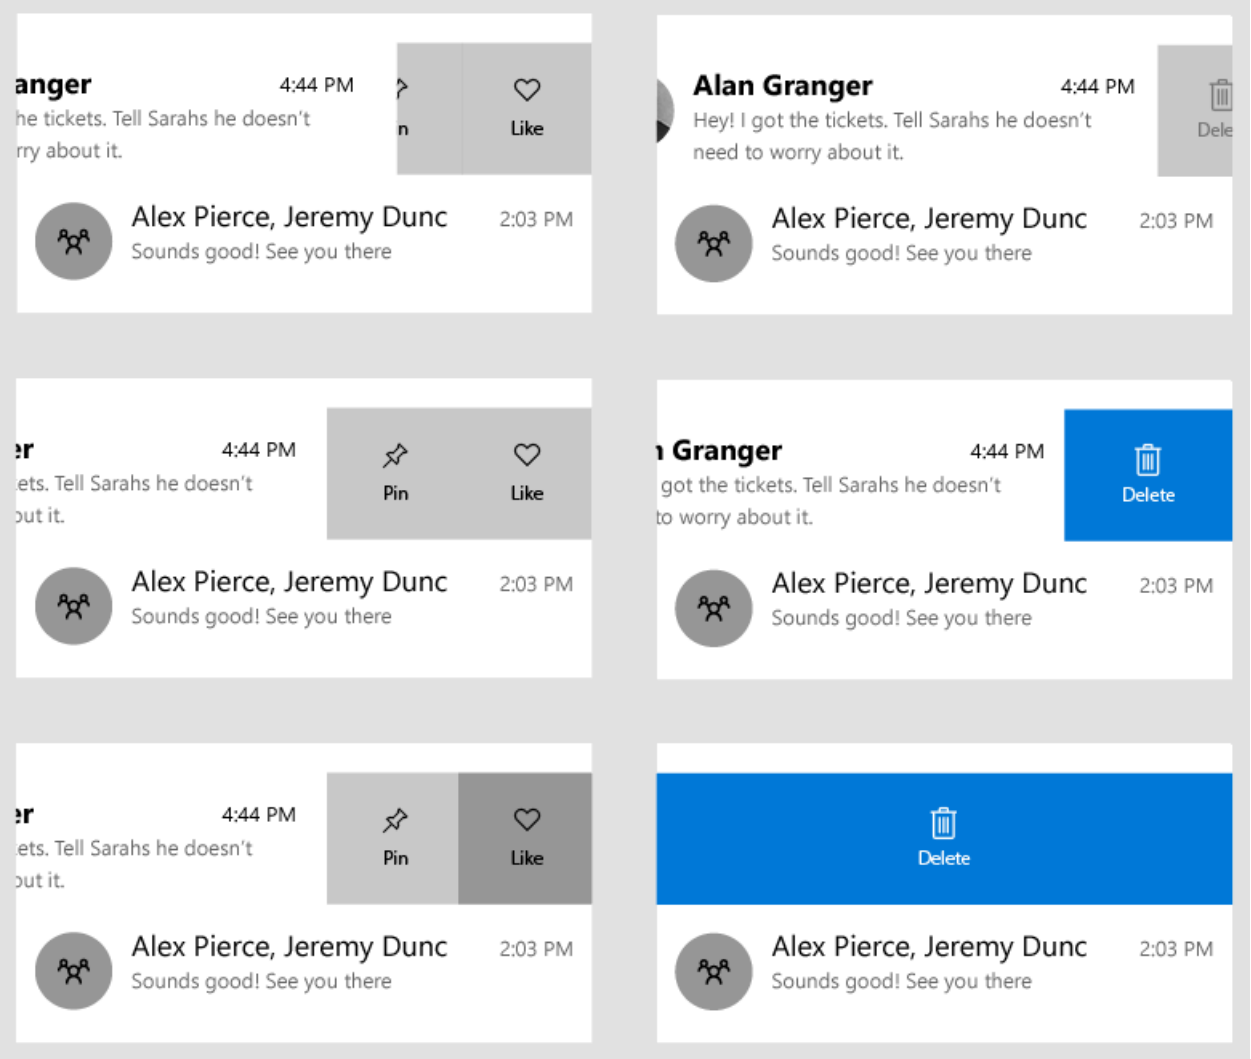
For command bar recommendations, see guidelines for command bars.

To learn more about selection modes and handling selection events for certain controls, visit the guidance page for that control.

Swipe

Article • 02/26/2025

Swipe commanding is an accelerator for context menus that lets users easily access common menu actions by touch, without needing to change states within the app.



Is this the right control?

Swipe commanding saves space. It's useful in situations where the user may perform the same operation on multiple items in quick succession. And it provides "quick actions" on items that don't need a full popup or state change within the page.

You should use swipe commanding when you have a potentially large group of items, and each item has 1-3 actions that a user may want to perform regularly. These actions may include, but are not limited to:

- Deleting
- Marking or archiving

- Saving or downloading
- Replying

How does Swipe work?

UWP swipe commanding has two modes: Reveal and Execute. It also supports four different swipe directions: up, down, left, and right.

Reveal mode

In Reveal mode, the user swipes an item to open a menu of one or more commands and must explicitly tap a command to execute it. When the user swipes and releases an item, the menu remains open until either a command is selected, or the menu is closed again through swiping back, tapping off, or scrolling the opened swipe item off the screen.

Reveal mode is a safer, more versatile swipe mode, and can be used for most types of menu actions, even potentially destructive actions, such as deletion.

When the user selects one of the menu options shown in the reveal's open and resting state, the command for that item is invoked and the swipe control is closed.

Execute mode

In Execute mode, the user swipes an item open to reveal and execute a single command with that one swipe. If the user releases the item being swiped before they swipe past a threshold, the menu closes and the command is not executed. If the user swipes past the threshold and then releases the item, the command is executed immediately.

If the user does not release their finger after the threshold is reached, and pulls the swipe item closed again, the command is not executed and no action is performed on the item.

Execute mode provides more visual feedback through color and label orientation while an item is being swiped.

Execute is best used when the action the user is performing is most common.

It may also be used for more destructive actions like deleting an item. However, keep in mind that Execute requires only one action of swiping in a direction, as opposed to Reveal, which requires the user to explicitly click on a button.

Swipe directions

Swipe works in all cardinal directions: up, down, left, and right. Each swipe direction can hold its own swipe items or content, but only one instance of a direction can be set at a time on a single swipe-able element.

For example, you cannot have two LeftItems definitions on the same SwipeControl.

Dos and don'ts

- Don't use swipe in FlipViews or Hubs. The combination may be confusing for the user because of conflicting swipe directions.
- Don't combine horizontal swipe with horizontal navigation, or vertical swipe with vertical navigation.
- Do make sure what the user is swiping is the same action, and is consistent across all related items that can be swiped.

- Do use swipe for the main actions a user will want to perform.
- Do use swipe on items where the same action is repeated many times.
- Do use horizontal swiping on wider items, and vertical swiping on taller items.
- Do use short, concise text labels.

Create a swipe command

✔ **Important APIs**: SwipeControl, SwipeItem, ListView class

Open the WinUI 3 Gallery app and see SwipeControl in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

Swipe commands have two components that you need to define:

- The SwipeControl, which wraps around your content. In a collection, such as a ListView, this sits within your DataTemplate.
- The swipe menu items, which is one or more SwipeItem objects placed in the swipe control's directional containers: LeftItems, RightItems, TopItems, or BottomItems

Swipe content can be placed inline, or defined in the Resources section of your page or app.

Here's a simple example of a SwipeControl wrapped around some text. It shows the hierarchy of XAML elements required to create a swipe command.

XAML

```
<SwipeControl HorizontalAlignment="Center" VerticalAlignment="Center">
    <SwipeControl.LeftItems>
        <SwipeItems>
            <SwipeItem Text="Pin">
                <SwipeItem.IconSource>
                    <SymbolIconSource Symbol="Pin"/>
                </SwipeItem.IconSource>
            </SwipeItem>
        </SwipeItems>
    </SwipeControl.LeftItems>

     <!-- Swipeable content -->
    <Border Width="180" Height="44" BorderBrush="Black" BorderThickness="2">
        <TextBlock Text="Swipe to Pin" Margin="4,8,0,0"/>
```

```
    </Border>
</SwipeControl>
```

Now we'll take a look at a more complete example of how you would typically use swipe commands in a list. In this example, you'll set up a delete command that uses Execute mode, and a menu of other commands that uses Reveal mode. Both sets of commands are defined in the Resources section of the page. You'll apply the swipe commands to the items in a ListView.

First, create the swipe items, which represent the commands, as page level resources. SwipeItem uses an IconSource as its icon. Create the icons as resources, too.

XAML

```
<Page.Resources>
    <SymbolIconSource x:Key="ReplyIcon" Symbol="MailReply"/>
    <SymbolIconSource x:Key="DeleteIcon" Symbol="Delete"/>
    <SymbolIconSource x:Key="PinIcon" Symbol="Pin"/>

    <SwipeItems x:Key="RevealOptions" Mode="Reveal">
        <SwipeItem Text="Reply" IconSource="{StaticResource ReplyIcon}"/>
        <SwipeItem Text="Pin" IconSource="{StaticResource PinIcon}"/>
    </SwipeItems>

    <SwipeItems x:Key="ExecuteDelete" Mode="Execute">
        <SwipeItem Text="Delete" IconSource="{StaticResource DeleteIcon}"
                   Background="Red"/>
    </SwipeItems>
</Page.Resources>
```

Remember to keep the menu items in your swipe content to short, concise text labels. These actions should be the primary ones that a user may want to perform multiple times over a short period.

Setting up a swipe command to work in a collection or ListView is exactly the same as defining a single swipe command (shown previously), except you define your SwipeControl in a DataTemplate so it's applied to each item in the collection.

Here's a ListView with the SwipeControl applied in its item DataTemplate. The LeftItems and RightItems properties reference the swipe items that you created as resources.

XAML

```
<ListView x:Name="sampleList" Width="300">
    <ListView.ItemContainerStyle>
        <Style TargetType="ListViewItem">
            <Setter Property="HorizontalContentAlignment" Value="Stretch"/>
            <Setter Property="VerticalContentAlignment" Value="Stretch"/>
```

```
        </Style>
    </ListView.ItemContainerStyle>
    <ListView.ItemTemplate>
        <DataTemplate x:DataType="x:String">
            <SwipeControl x:Name="ListViewSwipeContainer"
                          LeftItems="{StaticResource RevealOptions}"
                          RightItems="{StaticResource ExecuteDelete}"
                          Height="60">
                <StackPanel Orientation="Vertical">
                    <TextBlock Text="{x:Bind}" FontSize="18"/>
                    <StackPanel Orientation="Horizontal">
                        <TextBlock Text="Lorem ipsum dolor sit amet,
consectetur adipiscing elit..." FontSize="12"/>
                    </StackPanel>
                </StackPanel>
            </SwipeControl>
        </DataTemplate>
    </ListView.ItemTemplate>
    <x:String>Item 1</x:String>
    <x:String>Item 2</x:String>
    <x:String>Item 3</x:String>
    <x:String>Item 4</x:String>
    <x:String>Item 5</x:String>
</ListView>
```

Handle an invoked swipe command

To act on a swipe command, you handle its Invoked event. (For more info about a how a user can invoke a command, review the *How does swipe work?* section earlier in this article.) Typically, a swipe command is in a ListView or list-like scenario. In that case, when a command is invoked, you want to perform an action on that swiped item.

Here's how to handle the Invoked event on the *delete* swipe item you created previously.

XAML

```
<SwipeItems x:Key="ExecuteDelete" Mode="Execute">
    <SwipeItem Text="Delete" IconSource="{StaticResource DeleteIcon}"
               Background="Red" Invoked="Delete_Invoked"/>
</SwipeItems>
```

The data item is the DataContext of the SwipeControl. In your code, you can access the item that was swiped by getting the SwipeControl.DataContext property from the event args, as shown here.

C#

```
 private void Delete_Invoked(SwipeItem sender, SwipeItemInvokedEventArgs
args)
 {
     sampleList.Items.Remove(args.SwipeControl.DataContext);
 }
```

> **Note**
>
> Here, the items were added directly to the ListView.Items collection for simplicity, so the item is also deleted the same way. If you instead set the ListView.ItemsSource to a collection, which is more typical, you need to delete the item from the source collection.

In this particular instance, you removed the item from the list, so the final visual state of the swiped item isn't important. However, in situations where you simply want to perform an action and then have the swipe collapse again, you can set the BehaviorOnInvoked property one of the SwipeBehaviorOnInvoked enum values.

- **Auto**
  - In Execute mode, the opened swipe item will remain open when invoked.
  - In Reveal mode, the opened swipe item will collapse when invoked.
- **Close**
  - When the item is invoked, the swipe control will always collapse and return to normal, regardless of the mode.
- **RemainOpen**
  - When the item is invoked, the swipe control will always stay open, regardless of the mode.

Here, a *reply* swipe item is set to close after its invoked.

XAML

```
<SwipeItem Text="Reply" IconSource="{StaticResource ReplyIcon}"
           Invoked="Reply_Invoked"
           BehaviorOnInvoked = "Close"/>
```

UWP and WinUI 2

> **Important**

The information and examples in this article are optimized for apps that use the **Windows App SDK** and **WinUI 3**, but are generally applicable to UWP apps that use **WinUI 2**. See the UWP API reference for platform specific information and examples.

This section contains information you need to use the control in a UWP or WinUI 2 app.

The SwipeControl for UWP apps is included as part of WinUI 2. For more info, including installation instructions, see WinUI 2. APIs for this control exist in both the Windows.UI.Xaml.Controls (UWP) and Microsoft.UI.Xaml.Controls (WinUI) namespaces.

- ✓ **UWP APIs:** SwipeControl, SwipeItem, ListView class
- ✓ **WinUI 2 Apis:** SwipeControl, SwipeItem
- ✓ Open the WinUI 2 Gallery app and see SwipeControl in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles, templates, and features for all controls.

To use the code in this article with WinUI 2, use an alias in XAML (we use `muxc`) to represent the Windows UI Library APIs that are included in your project. See Get Started with WinUI 2 for more info.

XAML

```
xmlns:muxc="using:Microsoft.UI.Xaml.Controls"

<muxc:SwipeControl />
<muxc:SwipeItem />
```

Pull to refresh

Article • 02/26/2025

Pull-to-refresh lets a user pull down on a list of data using touch in order to retrieve more data. Pull-to-refresh is widely used on devices with a touch screen. You can use the APIs shown here to implement pull-to-refresh in your app.

Is this the right control?

Use pull-to-refresh when you have a list or grid of data that the user might want to refresh regularly, and your app is likely to be running on touch-first devices.

You can also use the RefreshVisualizer to create a consistent refresh experience that is invoked in other ways, such as by a refresh button.

Refresh controls

Pull-to-refresh is enabled by 2 controls.

- **RefreshContainer** - a ContentControl that provides a wrapper for the pull-to-refresh experience. It handles the touch interactions and manages the state of its internal refresh visualizer.

- **RefreshVisualizer** - encapsulates the refresh visualization explained in the next section.

The main control is the **RefreshContainer**, which you place as a wrapper around the content that the user pulls to trigger a refresh. RefreshContainer works only with touch, so we recommend that you also have a refresh button available for users who don't have a touch interface. You can position the refresh button at a suitable location in the app, either on a command bar or at a location close to the surface being refreshed.

Refresh visualization

The default refresh visualization is a circular progress spinner that is used to communicate when a refresh will happen and the progress of the refresh after it is initiated. The refresh visualizer has 5 states.

The distance the user needs to pull down on a list to initiate a refresh is called the *threshold*. The visualizer State is determined by the pull state as it relates to this threshold. The possible values are contained in the RefreshVisualizerState enumeration.

Idle

The visualizer's default state is **Idle**. The user is not interacting with the RefreshContainer via touch, and there is not a refresh in progress.

Visually, there is no evidence of the refresh visualizer.

Interacting

When the user pulls the list in the direction specified by the PullDirection property, and before the threshold is reached, the visualizer is in the **Interacting** state.

- If the user releases the control while in this state, the control returns to **Idle**.

Visually, the icon is displayed as disabled (60% opacity). In addition, the icon spins one full rotation with the scroll action.

- If the user pulls the list past the threshold, the visualizer transitions from **Interacting** to **Pending**.

Visually, the icon switches to 100% opacity and pulses in size up to 150% and then back to 100% size during the transition.

Pending

When the user has pulled the list past the threshold, the visualizer is in the **Pending** state.

- If the user moves the list back above the threshold without releasing it, it returns to the **Interacting** state.

- If the user releases the list, a refresh request is initiated and it transitions to the **Refreshing** state.

Visually, the icon is 100% in both size and opacity. In this state, the icon continues to move down with the scroll action but no longer spins.

Refreshing

When the user releases the visualiser past the threshold, it's in the **Refreshing** state.

When this state is entered, the **RefreshRequested** event is raised. This is the signal to start the app's content refresh. The event args (RefreshRequestedEventArgs) contain a Deferral object, which you should take a handle to in the event handler. Then, you should mark the deferral as completed when your code to perform the refresh has completed.

When the refresh is complete, the visualizer returns to the **Idle** state.

Visually, the icon settles back to the threshold location and spins for the duration of the refresh. This spinning is used to show progress of the refresh and is replaced by the animation of the incoming content.

Peeking

When the user pulls in the refresh direction from a start position where a refresh is not allowed, the visualizer enters the **Peeking** state. This typically happens when the ScrollViewer is not at position 0 when the user starts to pull.

- If the user releases the control while in this state, the control returns to **Idle**.

Pull direction

By default, the user pulls a list from top to bottom to initiate a refresh. If you have a list or grid with a different orientation, you should change the pull direction of the refresh container to match.

The PullDirection property takes one of these RefreshPullDirection values: **BottomToTop**, **TopToBottom**, **RightToLeft**, or **LeftToRight**.

When you change the pull direction, the starting position of the visualizer's progress spinner automatically rotates so the arrow starts in the appropriate position for the pull direction. If needed, you can change the RefreshVisualizer.Orientation property to override the automatic behavior. In most cases, we recommend leaving the default value of **Auto**.

Implement pull-to-refresh

✓ **Important APIs**: RefreshContainer, RefreshVisualizer

Open the WinUI 3 Gallery app and see PullToRefresh in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

To add pull-to-refresh functionality to a list requires just a few steps.

1. Wrap your list in a **RefreshContainer** control.
2. Handle the **RefreshRequested** event to refresh your content.
3. Optionally, initiate a refresh by calling **RequestRefresh** (for example, from a button click).

> **Note**
>
> You can instantiate a RefreshVisualizer on its own. However, we recommend that you wrap your content in a RefreshContainer and use the RefreshVisualizer provided by the RefreshContainer.Visualizer property, even for non-touch scenarios. In this article, we assume that the visualizer is always obtained from the refresh container.
>
> In addition, use the refresh container's RequestRefresh and RefreshRequested members for convenience. `refreshContainer.RequestRefresh()` is equivalent to

`refreshContainer.Visualizer.RequestRefresh()`, and either will raise both the RefreshContainer.RefreshRequested event and the RefreshVisualizer.RefreshRequested events.

Request a refresh

The refresh container handles touch interactions to let a user refresh content via touch. We recommend that you provide other affordances for non-touch interfaces, like a refresh button or voice control.

To initiate a refresh, call the RequestRefresh method.

C#

```
// See the Examples section for the full code.
private void RefreshButtonClick(object sender, RoutedEventArgs e)
{
    RefreshContainer.RequestRefresh();
}
```

When you call RequestRefresh, the visualizer state goes directly from **Idle** to **Refreshing**.

Handle a refresh request

To get fresh content when needed, handle the RefreshRequested event. In the event handler, you'll need code specific to your app to get the fresh content.

The event args (RefreshRequestedEventArgs) contain a Deferral object. Get a handle to the deferral in the event handler. Then, mark the deferral as completed when your code to perform the refresh has completed.

C#

```
// See the Examples section for the full code.
private async void RefreshContainer_RefreshRequested(RefreshContainer
sender, RefreshRequestedEventArgs args)
{
    // Respond to a request by performing a refresh and using the deferral
object.
    using (var RefreshCompletionDeferral = args.GetDeferral())
    {
        // Do some async operation to refresh the content

         await FetchAndInsertItemsAsync(3);

        // The 'using' statement ensures the deferral is marked as complete.
```

```
        // Otherwise, you'd call
        // RefreshCompletionDeferral.Complete();
        // RefreshCompletionDeferral.Dispose();
    }
}
```

Respond to state changes

You can respond to changes in the visualizer's state, if needed. For example, to prevent multiple refresh requests, you can disable a refresh button while the visualizer is refreshing.

C#

```
// See the Examples section for the full code.
private void Visualizer_RefreshStateChanged(RefreshVisualizer sender,
RefreshStateChangedEventArgs args)
{
    // Respond to visualizer state changes.
    // Disable the refresh button if the visualizer is refreshing.
    if (args.NewState == RefreshVisualizerState.Refreshing)
    {
        RefreshButton.IsEnabled = false;
    }
    else
    {
        RefreshButton.IsEnabled = true;
    }
}
```

Using a ScrollViewer in a RefreshContainer

> **Note**
>
> The Content of a RefreshContainer must be a scrollable control, such as ScrollViewer, GridView, ListView, etc. Setting the Content to a control like Grid will result in undefined behavior.

This example shows how to use pull-to-refresh with a scroll viewer.

XAML

```
<RefreshContainer>
    <ScrollViewer VerticalScrollMode="Enabled"
                  VerticalScrollBarVisibility="Auto"
```

```
                    HorizontalScrollBarVisibility="Auto">

        <!-- Scrollviewer content -->

    </ScrollViewer>
</RefreshContainer>
```

Adding pull-to-refresh to a ListView

This example shows how to use pull-to-refresh with a list view.

XAML

```
<StackPanel Margin="0,40" Width="280">
    <CommandBar OverflowButtonVisibility="Collapsed">
        <AppBarButton x:Name="RefreshButton" Click="RefreshButtonClick"
                      Icon="Refresh" Label="Refresh"/>
        <CommandBar.Content>
            <TextBlock Text="List of items"
                       Style="{StaticResource TitleTextBlockStyle}"
                       Margin="12,8"/>

UWP and WinUI 2

> **ⓘ Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that

use **WinUI 2**. See the UWP API reference for platform specific information and examples.

This section contains information you need to use the control in a UWP or WinUI 2 app.

The refresh controls for UWP apps are included as part of WinUI 2. For more info, including installation instructions, see WinUI 2. APIs for this control exist in both the Windows.UI.Xaml.Controls (UWP) and Microsoft.UI.Xaml.Controls (WinUI) namespaces.

- ✔ **UWP APIs:** RefreshContainer, RefreshVisualizer
- ✔ **WinUI 2 Apis:** RefreshContainer, RefreshVisualizer
- ✔ Open the WinUI 2 Gallery app and see PullToRefresh in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles, templates, and features for all controls.

To use the code in this article with WinUI 2, use an alias in XAML (we use `muxc`) to represent the Windows UI Library APIs that are included in your project. See Get Started with WinUI 2 for more info.

XAML

```
xmlns:muxc="using:Microsoft.UI.Xaml.Controls"

<muxc:RefreshContainer />
```

Filtering collections and lists through user input

Article • 03/29/2024

If your collection displays many items or is heavily tied to user interaction, filtering is a useful feature to implement. Filtering using the method described in this article can be implemented with most collection controls, including ListView, GridView, and ItemsView. Many types of user input can be used to filter a collection - such as checkboxes, radio buttons, and sliders - but this article demonstrates taking text-based user input and using it to update a ListView in real time, according to the user's search.

Setting up the UI for filtering

To implement text filtering, your app will need a ListView and a TextBox or other control that allows user input. The text that the user types into the TextBox is used as the filter; that is, only results that contain the user's text input will appear in the ListView. As the user types into the TextBox, the ListView constantly updates with filtered results.

> **Note**
>
> This article demonstrates filtering with a ListView. However, the filtering that is demonstrated can also be applied to other collection controls such as GridView, ItemsView, or TreeView.

The following XAML shows a UI with a simple ListView along with an accompanying TextBox. In this example, the ListView displays a collection of `Contact` objects. `Contact` is a class defined in the code-behind, and each `Contact` object has the following properties: `FirstName`, `LastName`, and `Company`.

The user can type a filtering term into the TextBox to filter the list of `Contact` objects by last name. The TextBox has it's `x:Name` attribute set (`FilterByLastName`) so you can access the TextBox's Text property in the code-behind. You also handle it's TextChanged event (`OnFilterChanged`). The TextChanged event occurs whenever the user types in the TextBox, letting you perform a filtering operation upon receiving user input.

For filtering to work, the ListView must have a data source that can be manipulated in the code-behind, such as an ObservableCollection<T>. In this case, the ListView's

ItemsSource property is assigned to an `ObservableCollection<Contact>` in the code-behind.

> **Tip**
>
> This is a simplified version of the example in the ListView page of the **WinUI Gallery app**. Use the WinUI Gallery app to run and view the full code, including the ListView's **DataTemplate** and the `Contact` class.

XAML

```
<Grid>
    <StackPanel Width="300" Margin="24"
                HorizontalAlignment="Left">
        <TextBox x:Name="FilterByLastName"
                 Header="Filter by Last Name"
                 TextChanged="OnFilterChanged"/>
        <ListView x:Name="FilteredListView"
                  ItemTemplate="{StaticResource ContactListViewTemplate}"/>
    </StackPanel>
</Grid>
```

Filtering the data

Linq queries let you group, order, and select certain items in a collection. To filter a list, you construct a Linq query that selects only items that match the user-entered filtering term, entered in the `FilterByLastName` TextBox. The query result can be assigned to an IEnumerable<T> collection object. Once you have this collection, you can use it to compare with the original list, removing items that don't match and adding back items that do match (in case of a backspace).

> **Note**
>
> In order for the ListView to animate in the most intuitive way when adding and removing items, it's important to add and remove items in the ListView's **ItemsSource** collection itself, rather than create a new collection of filtered objects and assign that to the ListView's ItemsSource property.

To start, you'll need to initialize your original data source in a separate collection, such as a List<T>. In this example, you have a `List<Contact>` called `allContacts` that holds all of the `Contact` objects that can potentially be shown in the ListView.

You'll also need a collection to hold the filtered data, which will constantly change every time a filter is applied. For this, you'll use an ObservableCollection<T> so that the ListView is notified to update whenever the collection changes. In this example, it's an `ObservableCollection<Person>` called `contactsFiltered`, and is the ItemsSource for the ListView. At initialization, it will have the same contents as `allContacts`.

The filtering operation is performed through these steps, shown in the following code:

- Set the ListView's ItemsSource property to `contactsFiltered`.
- Handle the TextChanged event (`OnFilterChanged`) for the `FilterByLastName` TextBox. Inside this event handler function, filter the data.
- To filter the data, access the user-entered filtering term through the `FilterByLastName.Text` property. Use a Linq query to select the items in `allContacts` where the last name contains the term in `FilterByLastName.Text`, and add those matching items into a collection called `filtered`.
- Compare the current `contactsFiltered` collection with the newly filtered items in `filtered`, removing and adding items in `contactsFiltered` where necessary to make it match `filtered`.
- As items are removed and added in `contactsFiltered`, the ListView updates and animates accordingly.

C#

```
using System.Linq;

public sealed partial class MainPage : Page
{
   // Define Contact collection to hold all Contact objects.
   IList<Contact> allContacts = new List<Contact>();
   // Define an ObservableCollection<Contact> object to serve as the
ListView's
   // ItemsSource. This collection will get updated after the filters are
used:
   ObservableCollection<Contact> contactsFiltered;

   public MainPage()
   {
       this.InitializeComponent();

       // Populate allContacts collection.
       allContacts.Add(new Contact("Kendall", "Collins", "Adatum
Corporation"));
       allContacts.Add(new Contact("Victoria", "Burke", "Bellows College"));
       allContacts.Add(new Contact("Preston", "Morales", "Margie's
Travel"));
       allContacts.Add(new Contact("Miguel", "Reyes", "Tailspin Toys"));
```

```
        // Populate contactsFiltered with all Contact objects (in this case,
        // allContacts holds all of our Contact objects so we copy them into
        // contactsFiltered). Set this newly populated collection as the
        // ItemsSource for the ListView.
        contactsFiltered = new ObservableCollection<Contact>(allContacts);
        Filtereditemscontrol.itemssource = contactsFiltered;
    }

    // Whenever text changes in the filtering text box, this function is
called:
    private void OnFilterChanged(object sender, TextChangedEventArgs args)
    {
        // This is a Linq query that selects only items that return true
after
        // being passed through the Filter function, and adds all of those
        // selected items to filtered.
        var filtered = allContacts.Where(contact => Filter(contact));
        Remove_NonMatching(filtered);
        AddBack_Contacts(filtered);
    }

    // The following functions are called inside OnFilterChanged:

    // When the text in any filter is changed, perform a check on each item
in
    // the original contact list to see if the item should be displayed. If
the
    // item passes the check, the function returns true and the item is added
to
    // the filtered list. Make sure all text is case-insensitive when
comparing.
    private bool Filter(Contact contact)
    {
        return contact.LastName.Contains
            (FilterByLastName.Text,
StringComparison.InvariantCultureIgnoreCase);
    }

    // These functions go through the current list being displayed
    // (contactsFiltered), and remove any items not in the filtered
collection
    // (any items that don't belong), or add back any items from the original
    // allContacts list that are now supposed to be displayed.
(Adding/removing
    // the items ensures the list view uses the desired add/remove
animations.)

    private void Remove_NonMatching(IEnumerable<Contact> filteredData)
    {
        for (int i = contactsFiltered.Count - 1; i >= 0; i--)
        {
            var item = contactsFiltered[i];
            // If contact is not in the filtered argument list,
            // remove it from the ListView's source.
            if (!filteredData.Contains(item))
```

```
            {
                contactsFiltered.Remove(item);
            }
        }
    }

    private void AddBack_Contacts(IEnumerable<Contact> filteredData)
    {
        foreach (var item in filteredData)
        {
            // If the item in the filtered list is not currently in
            // the ListView's source collection, add it back in.
            if (!contactsFiltered.Contains(item))
            {
                contactsFiltered.Add(item);
            }
        }
    }
}
```

Now, as the user types in their filtering string in the `FilterByLastName` TextBox, the ListView immediately updates to show only the people whose last name contains the filtering string.

Inverted lists

Article • 06/09/2022

You can use a list view to present a conversation in a chat experience with items that are visually distinct to represent the sender/receiver. Using different colors and horizontal alignment to separate messages from the sender/receiver helps the user quickly orient themselves in a conversation.

> **Important APIs**: ListView class, ItemsStackPanel class, ItemsUpdatingScrollMode property

You will typically need to present the list such that it appears to grow from the bottom up instead of from the top down. When a new message arrives and is added to the end, the previous messages slide up to make room drawing the user's attention to the latest arrival. However, if a user has scrolled up to view previous replies then the arrival of a new message must not cause a visual shift that would disrupt their focus.

Create an inverted list

To create an inverted list, use a list view with an ItemsStackPanel as its items panel. On the ItemsStackPanel, set the ItemsUpdatingScrollMode to KeepLastItemInView.

> **ⓘ Important**
>
> The **KeepLastItemInView** enum value is available starting with Windows 10, version 1607. You can't use this value when your app runs on earlier versions of Windows 10.

This example shows how to align the list view's items to the bottom and indicate that when there is a change to the items the last item should remain in view.

XAML

XAML

```
<ListView>
   <ListView.ItemsPanel>
       <ItemsPanelTemplate>
           <ItemsStackPanel VerticalAlignment="Bottom"
                            ItemsUpdatingScrollMode="KeepLastItemInView"/>
       </ItemsPanelTemplate>
   </ListView.ItemsPanel>
</ListView>
```

Recommendations

- Align messages from the sender/receiver on opposite sides to make the flow of conversation clear to users.
- Animate the existing messages out of the way to display the latest message if the user is already at the end of the conversation awaiting the next message.
- Don't disrupt the users focus by moving items if they're not reading the end of the conversation.

Nested UI in list items

Article • 06/09/2022

Nested UI is a user interface (UI) that exposes nested actionable controls enclosed inside a container that also can take independent focus.

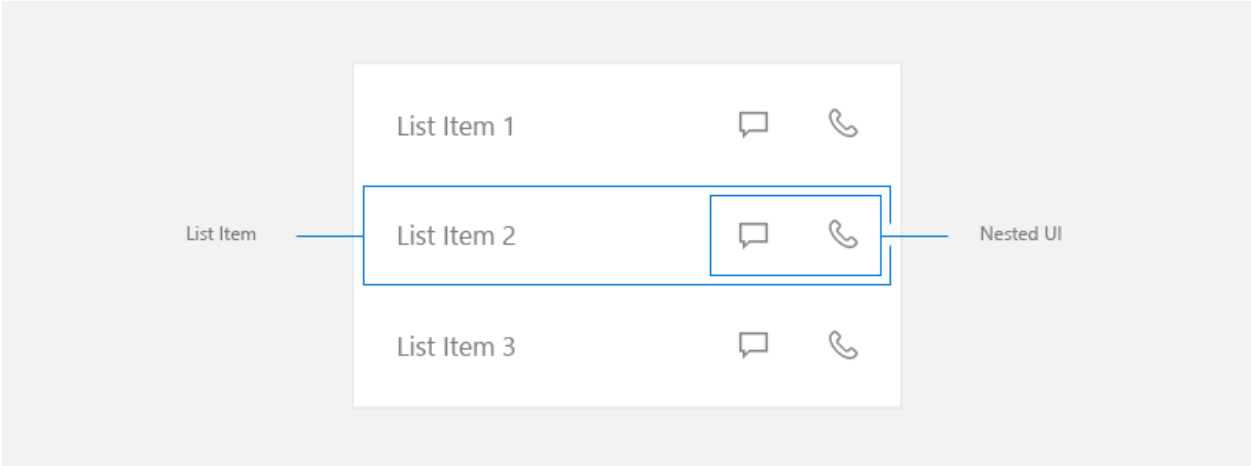
You can use nested UI to present a user with additional options that help accelerate taking important actions. However, the more actions you expose, the more complicated your UI becomes. You need to take extra care when you choose to use this UI pattern. This article provides guidelines to help you determine the best course of action for your particular UI.

> **Important APIs**: ListView class, GridView class

In this article, we discuss the creation of nested UI in ListView and GridView items. While this section does not talk about other nested UI cases, these concepts are transferrable. Before you start, you should be familiar with the general guidance for using ListView or GridView controls in your UI, which is found in the Lists and List view and grid view articles.

In this article, we use the terms *list*, *list item*, and *nested UI* as defined here:

- *List* refers to a collection of items contained in a list view or grid view.
- *List item* refers to an individual item that a user can take action on in a list.
- *Nested UI* refers to UI elements within a list item that a user can take action on separate from taking action on the list item itself.



> NOTE ListView and GridView both derive from the ListViewBase class, so they have the same functionality, but display data differently. In this article, when we talk about lists, the info applies to both the ListView and GridView controls.

Primary and secondary actions

When creating UI with a list, consider what actions the user might take from those list items.

- Can a user click on the item to perform an action?
  - Typically, clicking a list item initiates an action, but it doesn't have too.
- Is there more than one action the user can take?
  - For example, tapping an email in a list opens that email. However, there might be other actions, like deleting the email, that the user would want to take without opening it first. It would benefit the user to access this action directly in the list.
- How should the actions be exposed to the user?
  - Consider all input types. Some forms of nested UI work great with one method of input, but might not work with other methods.

The *primary action* is what the user expects to happen when they press the list item.

Secondary actions are typically accelerators associated with list items. These accelerators can be for list management or actions related to the list item.

Options for secondary actions

When creating list UI, you first need to make sure you account for all input methods that Windows supports. For more info about different kinds of input, see Input primer.

After you have made sure that your app supports all inputs that Windows supports, you should decide if your app's secondary actions are important enough to expose as accelerators in the main list. Remember that the more actions you expose, the more complicated your UI becomes. Do you really need to expose the secondary actions in the main list UI, or can you put them somewhere else?

You might consider exposing additional actions in the main list UI when those actions need to be accessible by any input at all times.

If you decide that putting secondary actions in the main list UI is not necessary, there are several other ways you can expose them to the user. Here are some options you can consider for where to place secondary actions.

Put secondary actions on the detail page

Put the secondary actions on the page that the list item navigates to when it's pressed. When you use the list/details pattern, the detail page is often a good place to put secondary actions.

For more info, see the list/detail pattern.

Put secondary actions in a context menu

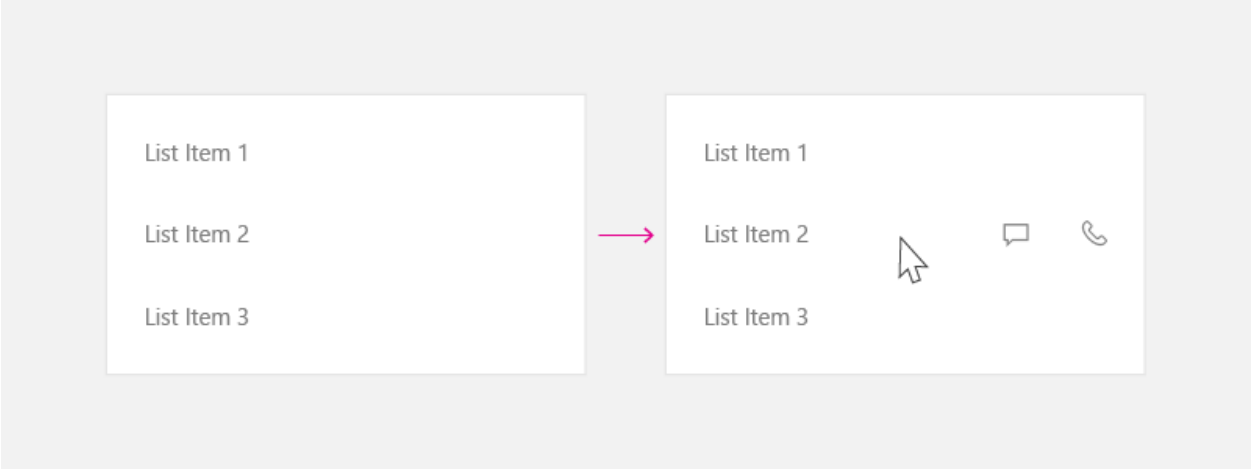
Put the secondary actions in a context menu that the user can access via right-click or press-and-hold. This provides the benefit of letting the user perform an action, such as deleting an email, without having to load the detail page. It's a good practice to also make these options available on the detail page, as context menus are intended to be accelerators rather than primary UI.

To expose secondary actions when input is from a gamepad or remote control, we recommend that you use a context menu.

For more info, see Context menus and flyouts.

Put secondary actions in hover UI to optimize for pointer input

If you expect your app to be used frequently with pointer input such as mouse and pen, and want to make secondary actions readily available only to those inputs, then you can show the secondary actions only on hover. This accelerator is visible only when a pointer input is used, so be sure to use the other options to support other input types as well.



For more info, see Mouse interactions.

UI placement for primary and secondary actions

If you decide that secondary actions should be exposed in the main list UI, we recommend the following guidelines.

When you create a list item with primary and secondary actions, place the primary action to the left and secondary actions to the right. In left-to-right reading cultures, users associate actions on the left side of list item as the primary action.

In these examples, we talk about list UI where the item flows more horizontally (it is wider than its height). However, you might have list items that are more square in shape, or taller than their width. Typically, these are items used in a grid. For these items, if the list doesn't scroll vertically, you can place the secondary actions at the bottom of the list item rather than to the right side.

Consider all inputs

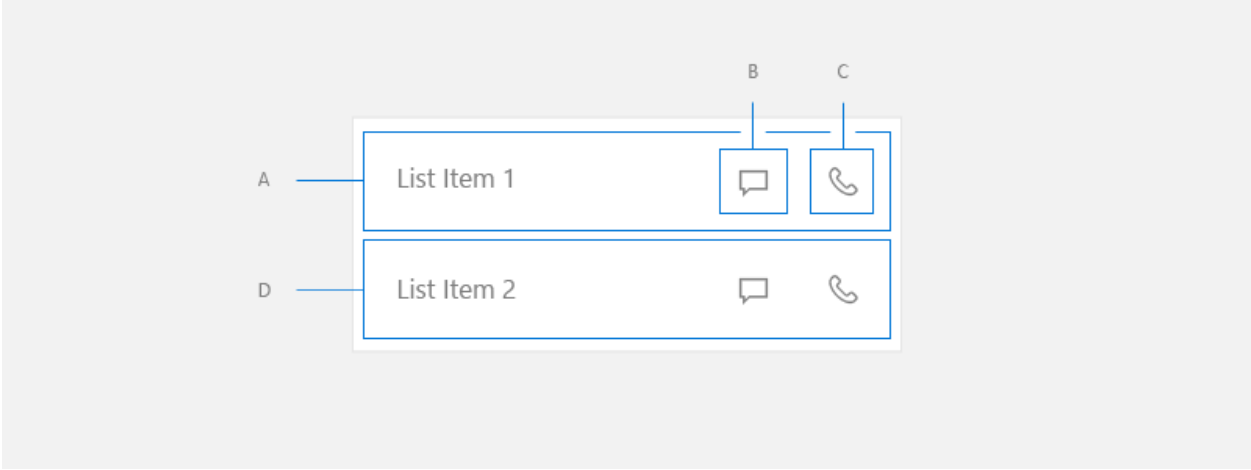
When deciding to use nested UI, also evaluate the user experience with all input types. As mentioned earlier, nested UI works great for some input types. However, it does not always work great for some other. In particular, keyboard, controller, and remote inputs can have difficulty accessing nested UI elements. Be sure to follow the guidance below to ensure your Windows works with all input types.

Nested UI handling

When you have more than one action nested in the list item, we recommend this guidance to handle navigation with a keyboard, gamepad, remote control, or other non-pointer input.

Nested UI where list items perform an action

If your list UI with nested elements supports actions such as invoking, selection (single or multiple), or drag-and-drop operations, we recommend these arrowing techniques to navigate through your nested UI elements.



Gamepad

When input is from a gamepad, provide this user experience:

- From **A**, right directional key puts focus on **B**.
- From **B**, right directional key puts focus on **C**.
- From **C**, right directional key is either no op, or if there is a focusable UI element to the right of List, put the focus there.
- From **C**, left directional key puts focus on **B**.
- From **B**, left directional key puts focus on **A**.
- From **A**, left directional key is either no op, or if there is a focusable UI element to the right of List, put the focus there.
- From **A**, **B**, or **C**, down directional key puts focus on **D**.
- From UI element to the left of List Item, right directional key puts focus on **A**.
- From UI element to the right of List Item, left directional key puts focus on **A**.

Keyboard

When input is from a keyboard, this is the experience user gets:

- From **A**, tab key puts focus on **B**.
- From **B**, tab key puts focus on **C**.
- From **C**, tab key puts focus on next focusable UI element in the tab order.
- From **C**, shift+tab key puts focus on **B**.
- From **B**, shift+tab or left arrow key puts focus on **A**.
- From **A**, shift+tab key puts focus on next focusable UI element in the reverse tab order.
- From **A**, **B**, or **C**, down arrow key puts focus on **D**.
- From UI element to the left of List Item, tab key puts focus on **A**.
- From UI element to the right of List Item, shift tab key puts focus on **C**.

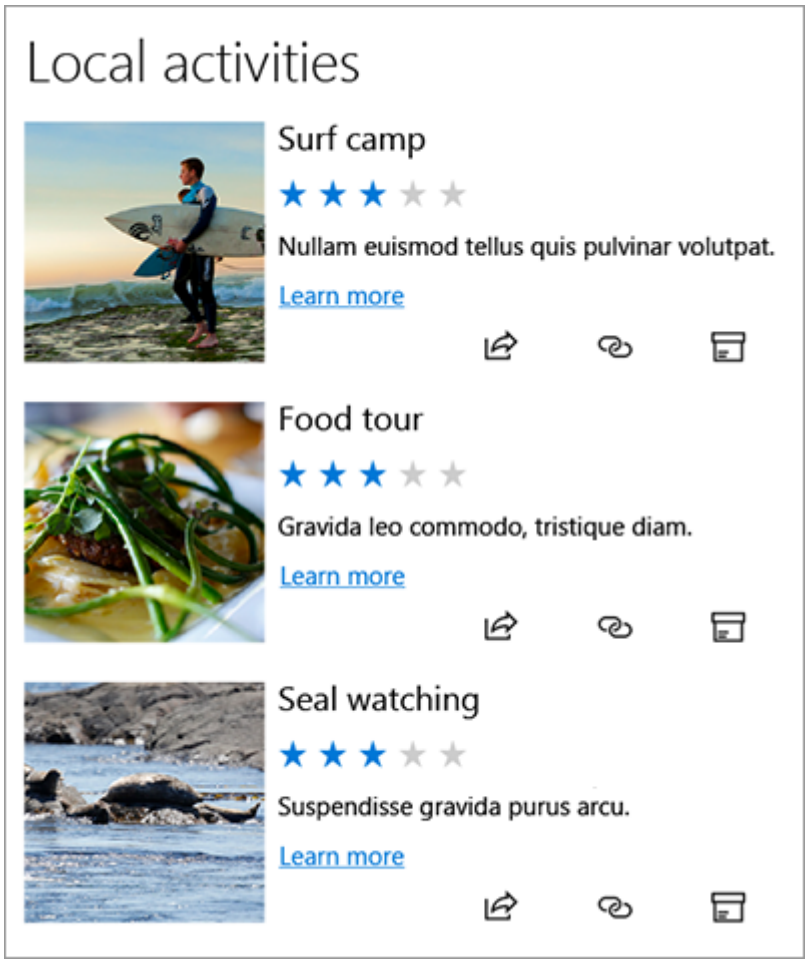
To achieve this UI, set IsItemClickEnabled to **true** on your list. SelectionMode can be any value.

For the code to implement this, see the Example section of this article.

Nested UI where list items do not perform an action

You might use a list view because it provides virtualization and optimized scrolling behavior, but not have an action associated with a list item. These UIs typically use the list item only to group elements and ensure they scroll as a set.

This kind of UI tends to be much more complicated than the previous examples, with a lot of nested elements that the user can take action on.



To achieve this UI, set the following properties on your list:

- SelectionMode to **None**.
- IsItemClickEnabled to **false**.
- IsFocusEngagementEnabled to **true**.

XAML

```
<ListView SelectionMode="None" IsItemClickEnabled="False" >
    <ListView.ItemContainerStyle>
        <Style TargetType="ListViewItem">
            <Setter Property="IsFocusEngagementEnabled" Value="True"/>
        </Style>
```

```
    </ListView.ItemContainerStyle>
</ListView>
```

When the list items do not perform an action, we recommend this guidance to handle navigation with a gamepad or keyboard.

Gamepad

When input is from a gamepad, provide this user experience:

- From List Item, down directional key puts focus on next List Item.
- From List Item, left/right key is either no op, or if there is a focusable UI element to the right of List, put the focus there.
- From List Item, 'A' button puts the focus on Nested UI in top/down left/right priority.
- While inside Nested UI, follow the XY Focus navigation model. Focus can only navigate around Nested UI contained inside the current List Item until user presses 'B' button, which puts the focus back onto the List Item.

Keyboard

When input is from a keyboard, this is the experience user gets:

- From List Item, down arrow key puts focus on the next List Item.
- From List Item, pressing left/right key is no op.
- From List Item, pressing tab key puts focus on the next tab stop amongst the Nested UI item.
- From one of the Nested UI items, pressing tab traverses the nested UI items in tab order. Once all the Nested UI items are traveled to, it puts the focus onto the next control in tab order after ListView.
- Shift+Tab behaves in reverse direction from tab behavior.

Example

This example shows how to implement nested UI where list items perform an action.

XAML

```
<ListView SelectionMode="None" IsItemClickEnabled="True"
          ChoosingItemContainer="listview1_ChoosingItemContainer"/>
```

C#

```
private void OnListViewItemKeyDown(object sender, KeyRoutedEventArgs e)
{
    // Code to handle going in/out of nested UI with gamepad and remote
only.
    if (e.Handled == true)
    {
        return;
    }

    var focusedElementAsListViewItem = FocusManager.GetFocusedElement() as
ListViewItem;
    if (focusedElementAsListViewItem != null)
    {
        // Focus is on the ListViewItem.
        // Go in with Right arrow.
        Control candidate = null;

        switch (e.OriginalKey)
        {
            case Windows.System.VirtualKey.GamepadDPadRight:
            case Windows.System.VirtualKey.GamepadLeftThumbstickRight:
                var rawPixelsPerViewPixel =
DisplayInformation.GetForCurrentView().RawPixelsPerViewPixel;
                GeneralTransform generalTransform =
focusedElementAsListViewItem.TransformToVisual(null);
                Point startPoint = generalTransform.TransformPoint(new
Point(0, 0));
                Rect hintRect = new Rect(startPoint.X *
rawPixelsPerViewPixel, startPoint.Y * rawPixelsPerViewPixel, 1,
focusedElementAsListViewItem.ActualHeight * rawPixelsPerViewPixel);
                candidate =
FocusManager.FindNextFocusableElement(FocusNavigationDirection.Right,
hintRect) as Control;
                break;
        }

        if (candidate != null)
        {
            candidate.Focus(FocusState.Keyboard);
            e.Handled = true;
        }
    }
    else
    {
        // Focus is inside the ListViewItem.
        FocusNavigationDirection direction = FocusNavigationDirection.None;
        switch (e.OriginalKey)
        {
            case Windows.System.VirtualKey.GamepadDPadUp:
            case Windows.System.VirtualKey.GamepadLeftThumbstickUp:
                direction = FocusNavigationDirection.Up;
                break;
            case Windows.System.VirtualKey.GamepadDPadDown:
            case Windows.System.VirtualKey.GamepadLeftThumbstickDown:
```

```
                direction = FocusNavigationDirection.Down;
                break;
            case Windows.System.VirtualKey.GamepadDPadLeft:
            case Windows.System.VirtualKey.GamepadLeftThumbstickLeft:
                direction = FocusNavigationDirection.Left;
                break;
            case Windows.System.VirtualKey.GamepadDPadRight:
            case Windows.System.VirtualKey.GamepadLeftThumbstickRight:
                direction = FocusNavigationDirection.Right;
                break;
            default:
                break;
        }

        if (direction != FocusNavigationDirection.None)
        {
            Control candidate =
FocusManager.FindNextFocusableElement(direction) as Control;
            if (candidate != null)
            {
                ListViewItem listViewItem = sender as ListViewItem;

                // If the next focusable candidate to the left is outside of
ListViewItem,
                // put the focus on ListViewItem.
                if (direction == FocusNavigationDirection.Left &&
                    !listViewItem.IsAncestorOf(candidate))
                {
                    listViewItem.Focus(FocusState.Keyboard);
                }
                else
                {
                    candidate.Focus(FocusState.Keyboard);
                }
            }

            e.Handled = true;
        }
    }
}

private void listview1_ChoosingItemContainer(ListViewBase sender,
ChoosingItemContainerEventArgs args)
{
    if (args.ItemContainer == null)
    {
        args.ItemContainer = new ListViewItem();
        args.ItemContainer.KeyDown += OnListViewItemKeyDown;
    }
}
```

C#

```
// DependencyObjectExtensions.cs definition.
public static class DependencyObjectExtensions
{
    public static bool IsAncestorOf(this DependencyObject parent,
DependencyObject child)
    {
        DependencyObject current = child;
        bool isAncestor = false;

        while (current != null && !isAncestor)
        {
            if (current == parent)
            {
                isAncestor = true;
            }

            current = VisualTreeHelper.GetParent(current);
        }

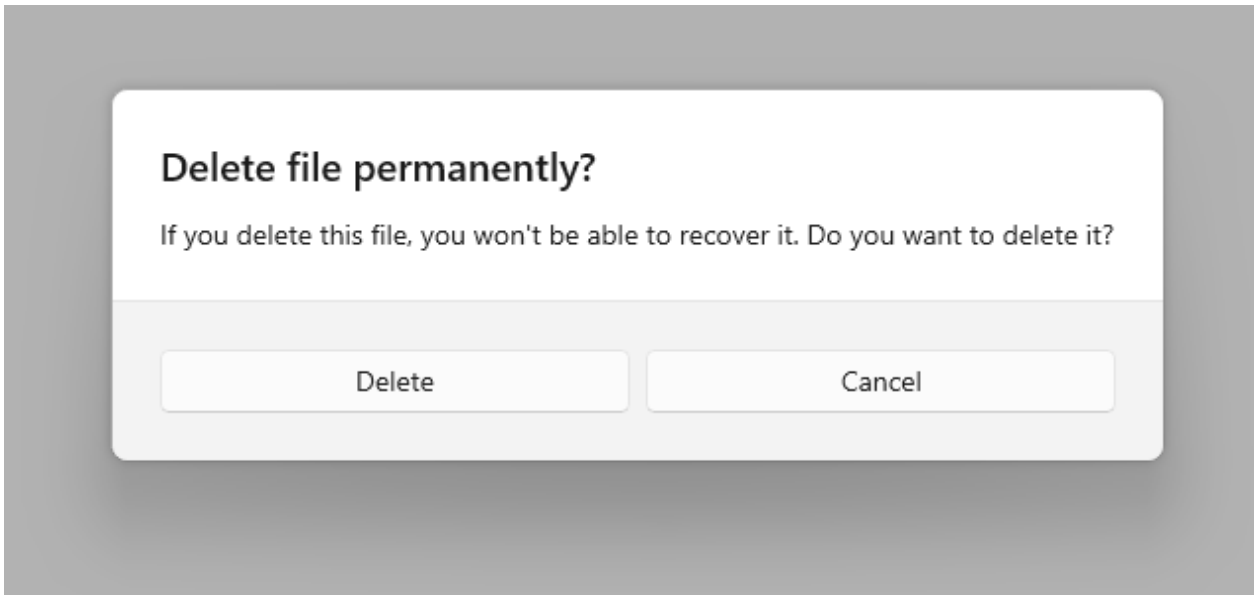
        return isAncestor;
    }
}
```

Dialogs and flyouts

Article • 10/13/2022

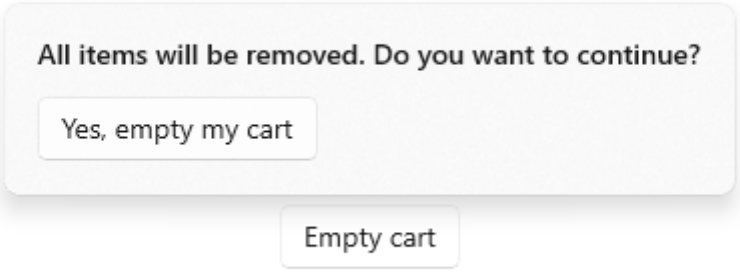
Dialogs and flyouts are transient UI elements that appear when something happens that requires notification, approval, or additional information from the user.

Dialogs



Dialogs are modal UI overlays that provide contextual app information. Dialogs block interactions with the app window until being explicitly dismissed. They often request some kind of action from the user.

Flyouts



A flyout is a lightweight contextual popup that displays UI related to what the user is doing. It includes placement and sizing logic, and can be used to reveal a secondary control or show more detail about an item.

Unlike a dialog, a flyout can be quickly dismissed by tapping or clicking somewhere outside the flyout, pressing the Escape key or Back button, resizing the app window, or changing the device's orientation.

Is this the right control?

Dialogs and flyouts make sure that users are aware of important information, but they also disrupt the user experience. Because dialogs are modal (blocking), they interrupt users, preventing them from doing anything else until they interact with the dialog. Flyouts provide a less jarring experience, but displaying too many flyouts can be distracting.

Once you've determined that you want to use a dialog or flyout, you need to choose which one to use.

Given that dialogs block interactions and flyouts do not, dialogs should be reserved for situations where you want the user to drop everything to focus on a specific bit of information or answer a question. Flyouts, on the other hand, can be used when you want to call attention to something, but it's ok if the user wants to ignore it.

Use a dialog for...

- Expressing important information that the user **must** read and acknowledge before proceeding. Examples include:
  - When the user's security might be compromised
  - When the user is about to permanently alter a valuable asset
  - When the user is about to delete a valuable asset
  - To confirm an in-app purchase
- Error messages that apply to the overall app context, such as a connectivity error.
- Questions, when the app needs to ask the user a blocking question, such as when the app can't choose on the user's behalf. A blocking question can't be ignored or postponed, and should offer the user well-defined choices.

Use a flyout for...

- Collecting additional information needed before an action can be completed.
- Displaying info that's only relevant some of the time. For example, in a photo gallery app, when the user clicks an image thumbnail, you might use a flyout to display a large version of the image.
- Displaying more information, such as details or longer descriptions of an item on the page.

Ways to avoid using dialogs and flyouts

Consider the importance of the information you want to share: is it important enough to interrupt the user? Also consider how frequently the information needs to be shown; if you're showing a dialog or notification every few minutes, you might want to allocate space for this info in the primary UI instead. For example, in a chat client, rather than showing a flyout every time a friend logs in, you might display a list of friends who are online at the moment and highlight friends as they log on.

Dialogs are frequently used to confirm an action (such as deleting a file) before executing it. If you expect the user to perform a particular action frequently, consider providing a way for the user to undo the action if it was a mistake, rather than forcing users to confirm the action every time.

Examples

✔ **Important APIs**: ContentDialog class, Flyout class

> - If you have the **WinUI 3 Gallery** app installed, click here to open the app and see the ContentDialog or Flyout in action. Get the app from the Microsoft Store or get the source code on GitHub.

How to create a dialog

See the Dialogs article.

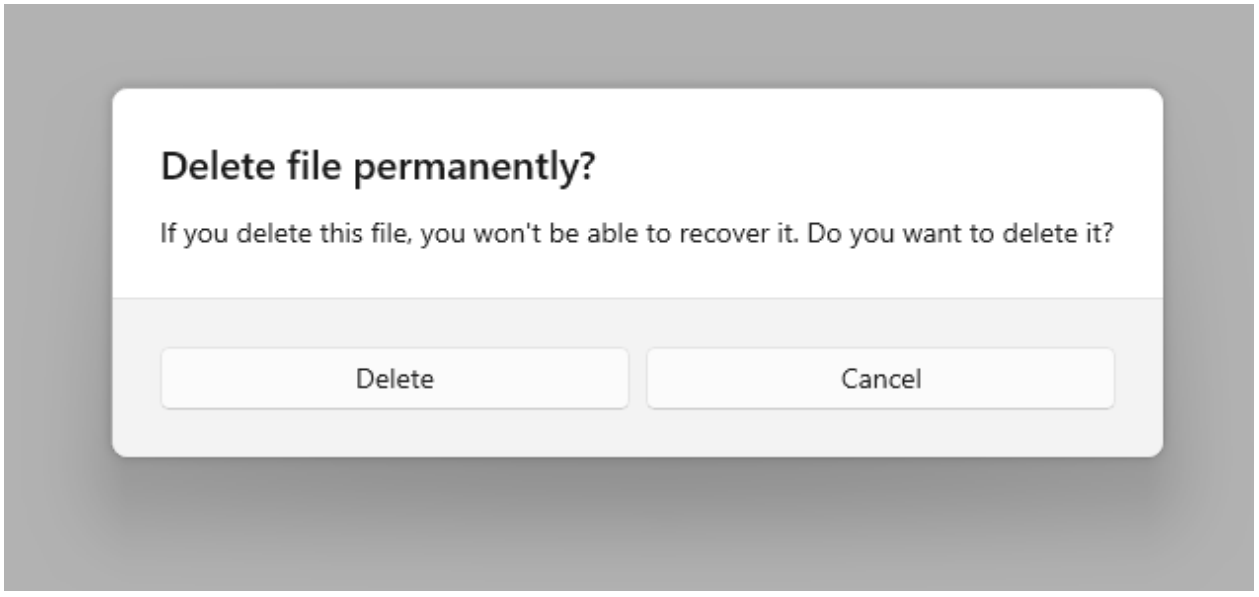
How to create a flyout

See the Flyout article.

Dialog controls

Article • 02/26/2025

Dialog controls are modal UI overlays that provide contextual app information. They block interactions with the app window until being explicitly dismissed. They often request some kind of action from the user.



Is this the right control?

Use dialogs to notify users of important information or to request confirmation or additional info before an action can be completed.

For recommendations on when to use a dialog vs. when to use a flyout (a similar control), see Dialogs and flyouts.

General guidelines

- Clearly identify the issue or the user's objective in the first line of the dialog's text.
- The dialog title is the main instruction and is optional.
  - Use a short title to explain what people need to do with the dialog.
  - If you're using the dialog to deliver a simple message, error or question, you can optionally omit the title. Rely on the content text to deliver that core information.
  - Make sure that the title relates directly to the button choices.
- The dialog content contains the descriptive text and is required.
  - Present the message, error, or blocking question as simply as possible.

    - If a dialog title is used, use the content area to provide more detail or define terminology. Don't repeat the title with slightly different wording.
- At least one dialog button must appear.
    - Ensure that your dialog has at least one button corresponding to a safe, nondestructive action like "Got it!", "Close", or "Cancel". Use the CloseButton API to add this button.
    - Use specific responses to the main instruction or content as button text. An example is, "Do you want to allow AppName to access your location?", followed by "Allow" and "Block" buttons. Specific responses can be understood more quickly, resulting in efficient decision making.
    - Ensure that the text of the action buttons is concise. Short strings enable the user to make a choice quickly and confidently.
    - In addition to the safe, nondestructive action, you may optionally present the user with one or two action buttons related to the main instruction. These "do it" action buttons confirm the main point of the dialog. Use the PrimaryButton and SecondaryButton APIs to add these "do it" actions.
    - The "do it" action button(s) should appear as the leftmost buttons. The safe, nondestructive action should appear as the rightmost button.
    - You may optionally choose to differentiate one of the three buttons as the dialog's default button. Use the DefaultButton API to differentiate one of the buttons.
- Don't use dialogs for errors that are contextual to a specific place on the page, such as validation errors (in password fields, for example), use the app's canvas itself to show inline errors.
- Use the ContentDialog class to build your dialog experience. Don't use the deprecated MessageDialog API.

Create a dialog

✔ **Important APIs**: ContentDialog class

Open the WinUI 3 Gallery app and see the ContentDialog in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

To create a dialog, you use the ContentDialog class. You can create a dialog in code or markup. Although its usually easier to define UI elements in XAML, in the case of a simple dialog, it's actually easier to just use code. This example creates a dialog to notify

the user that there's no WiFi connection, and then uses the ShowAsync method to display it.

C#

```
private async void DisplayNoWifiDialog()
{
    ContentDialog noWifiDialog = new ContentDialog
    {
        Title = "No wifi connection",
        Content = "Check your connection and try again.",
        CloseButtonText = "OK"
    };

    ContentDialogResult result = await noWifiDialog.ShowAsync();
}
```

When the user clicks a dialog button, the ShowAsync method returns a ContentDialogResult to let you know which button the user clicks.

The dialog in this example asks a question and uses the returned ContentDialogResult to determine the user's response.

C#

```
private async void DisplayDeleteFileDialog()
{
    ContentDialog deleteFileDialog = new ContentDialog
    {
        Title = "Delete file permanently?",
        Content = "If you delete this file, you won't be able to recover it.
Do you want to delete it?",
        PrimaryButtonText = "Delete",
        CloseButtonText = "Cancel"
    };

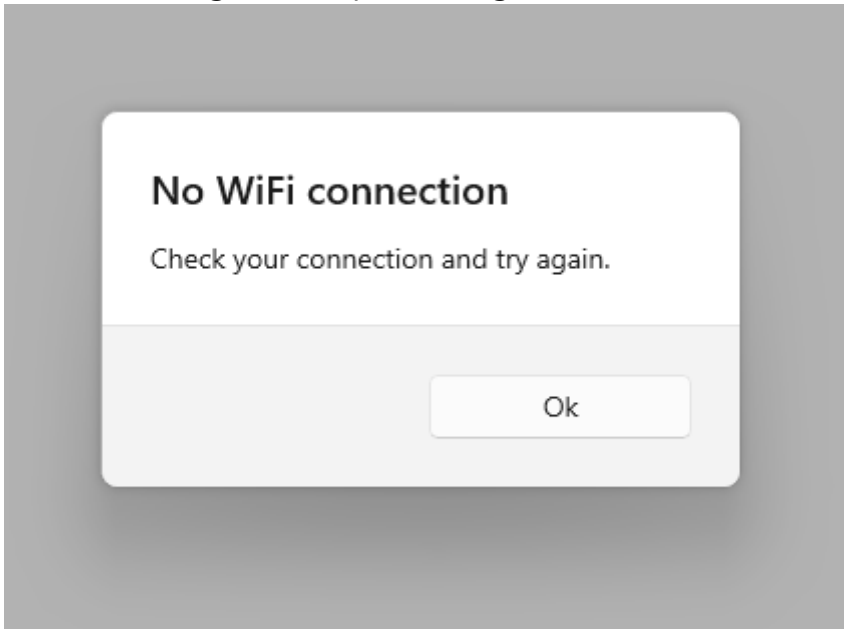
    ContentDialogResult result = await deleteFileDialog.ShowAsync();

    // Delete the file if the user clicked the primary button.
    /// Otherwise, do nothing.
    if (result == ContentDialogResult.Primary)
    {
        // Delete the file.
    }
    else
    {
        // The user clicked the CloseButton, pressed ESC, Gamepad B, or the
system back button.
        // Do nothing.
```

```
    }
}
```

Provide a safe action

Because dialogs block user interaction, and because buttons are the primary mechanism for users to dismiss the dialog, ensure that your dialog contains at least one "safe" and nondestructive button such as "Close" or "Got it!". **All dialogs should contain at least one safe action button to close the dialog.** This ensures that the user can confidently close the dialog without performing an action.

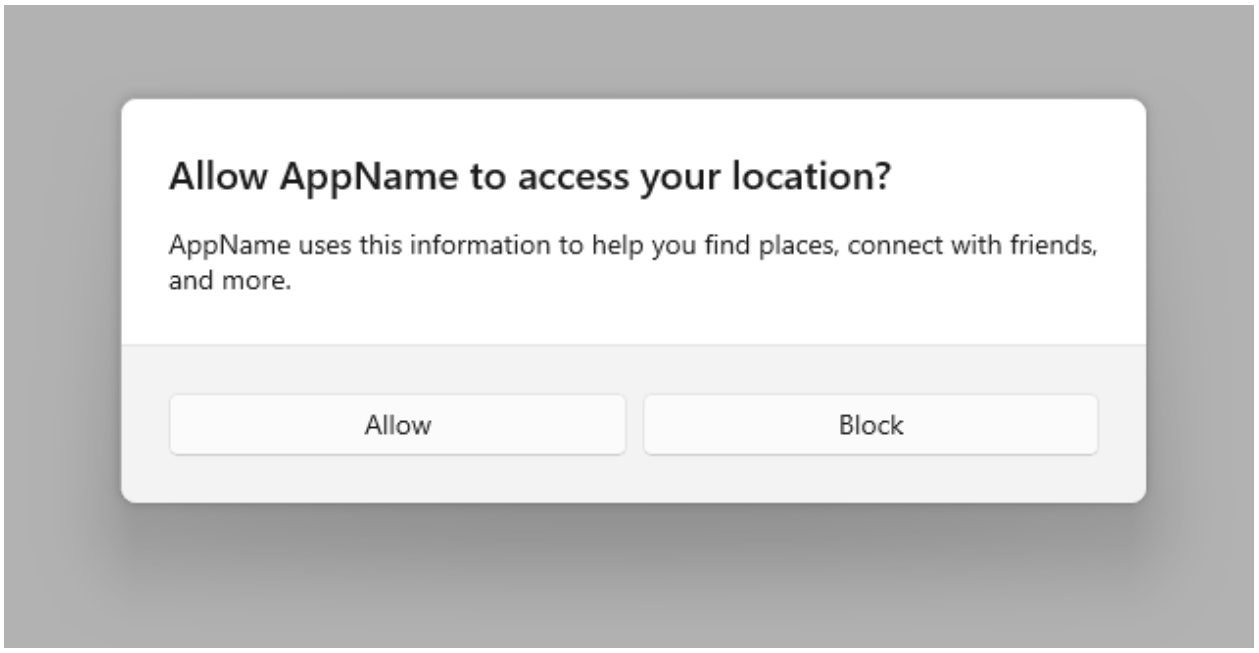


C#

```
private async void DisplayNoWifiDialog()
{
    ContentDialog noWifiDialog = new ContentDialog
    {
        Title = "No wifi connection",
        Content = "Check your connection and try again.",
        CloseButtonText = "OK"
    };

    ContentDialogResult result = await noWifiDialog.ShowAsync();
}
```

When dialogs are used to display a blocking question, your dialog should present the user with action buttons related to the question. The "safe" and nondestructive button may be accompanied by one or two "do it" action buttons. When presenting the user with multiple options, ensure that the buttons clearly explain the "do it" and safe/"don't do it" actions related to the question proposed.

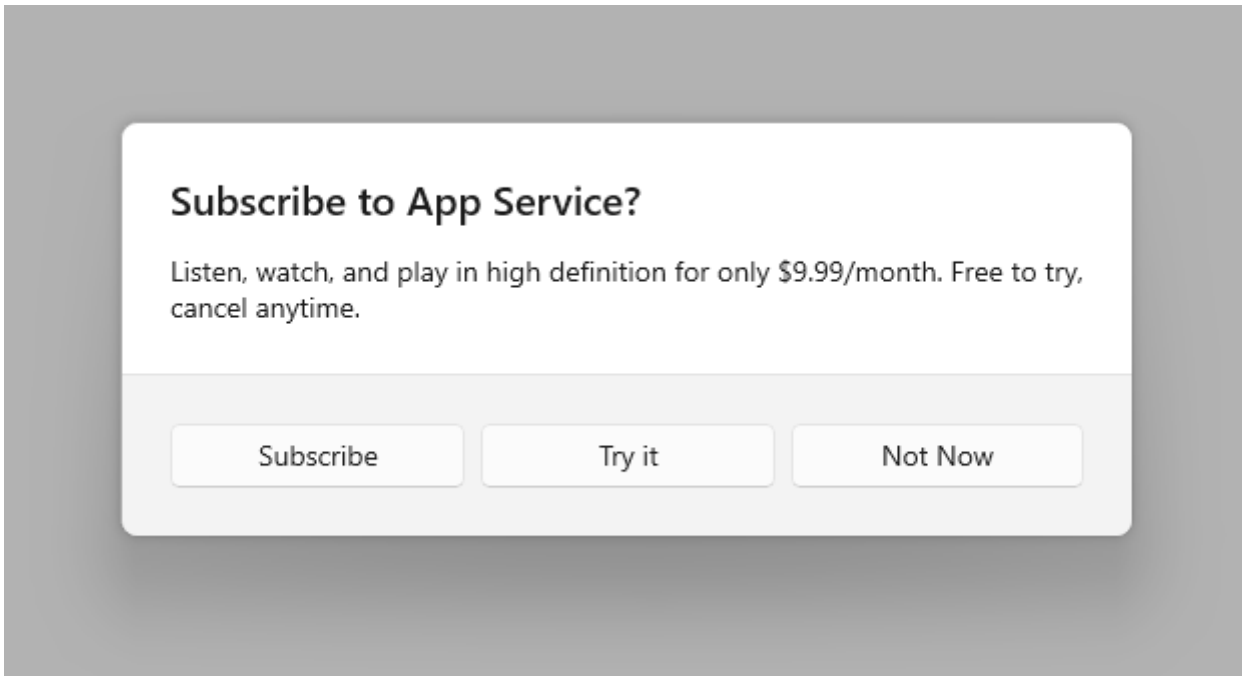


C#

```
private async void DisplayLocationPromptDialog()
{
    ContentDialog locationPromptDialog = new ContentDialog
    {
        Title = "Allow AppName to access your location?",
        Content = "AppName uses this information to help you find places,
connect with friends, and more.",
        CloseButtonText = "Block",
        PrimaryButtonText = "Allow"
    };

    ContentDialogResult result = await locationPromptDialog.ShowAsync();
}
```

Three button dialogs are used when you present the user with two "do it" actions and a "don't do it" action. Three button dialogs should be used sparingly with clear distinctions between the secondary action and the safe/close action.



C#

```
private async void DisplaySubscribeDialog()
{
    ContentDialog subscribeDialog = new ContentDialog
    {
        Title = "Subscribe to App Service?",
        Content = "Listen, watch, and play in high definition for only
$9.99/month. Free to try, cancel anytime.",
        CloseButtonText = "Not Now",
        PrimaryButtonText = "Subscribe",
        SecondaryButtonText = "Try it"
    };

    ContentDialogResult result = await subscribeDialog.ShowAsync();
}
```

The three dialog buttons

ContentDialog has three different types of buttons that you can use to build a dialog experience.

- **CloseButton** - Required - Represents the safe, nondestructive action that enables the user to exit the dialog. Appears as the rightmost button.
- **PrimaryButton** - Optional - Represents the first "do it" action. Appears as the leftmost button.
- **SecondaryButton** - Optional - Represents the second "do it" action. Appears as the middle button.

Using the built-in buttons will position the buttons appropriately, ensure that they correctly respond to keyboard events, ensure that the command area remains visible even when the on-screen keyboard is up, and will make the dialog look consistent with other dialogs.

CloseButton

Every dialog should contain a safe, nondestructive action button that enables the user to confidently exit the dialog.

Use the ContentDialog.CloseButton API to create this button. This allows you to create the right user experience for all inputs including mouse, keyboard, touch, and gamepad. This experience will happen when:

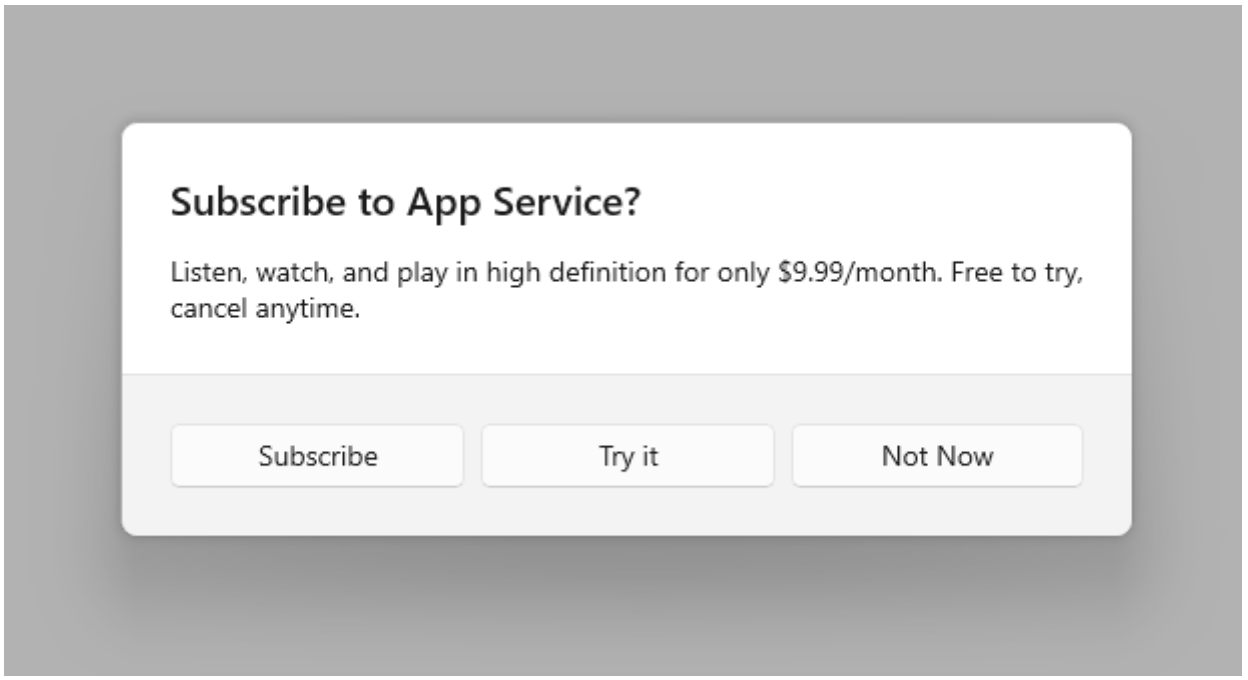
- The user clicks or taps on the CloseButton.
- The user presses the system back button.
- The user presses the ESC button on the keyboard.
- The user presses Gamepad B.

When the user clicks a dialog button, the ShowAsync method returns a ContentDialogResult to let you know which button the user clicks. Pressing on the CloseButton returns ContentDialogResult.None.

PrimaryButton and SecondaryButton

In addition to the CloseButton, you may optionally present the user with one or two action buttons related to the main instruction. Leverage PrimaryButton for the first "do it" action, and SecondaryButton for the second "do it" action. In three-button dialogs, the PrimaryButton generally represents the affirmative "do it" action, while the SecondaryButton generally represents a neutral or secondary "do it" action. For example, an app may prompt the user to subscribe to a service. The PrimaryButton as the affirmative "do it" action would host the Subscribe text, while the SecondaryButton as the neutral "do it" action would host the Try it text. The CloseButton would allow the user to cancel without performing either action.

When the user clicks on the PrimaryButton, the ShowAsync method returns ContentDialogResult.Primary. When the user clicks on the SecondaryButton, the ShowAsync method returns ContentDialogResult.Secondary.

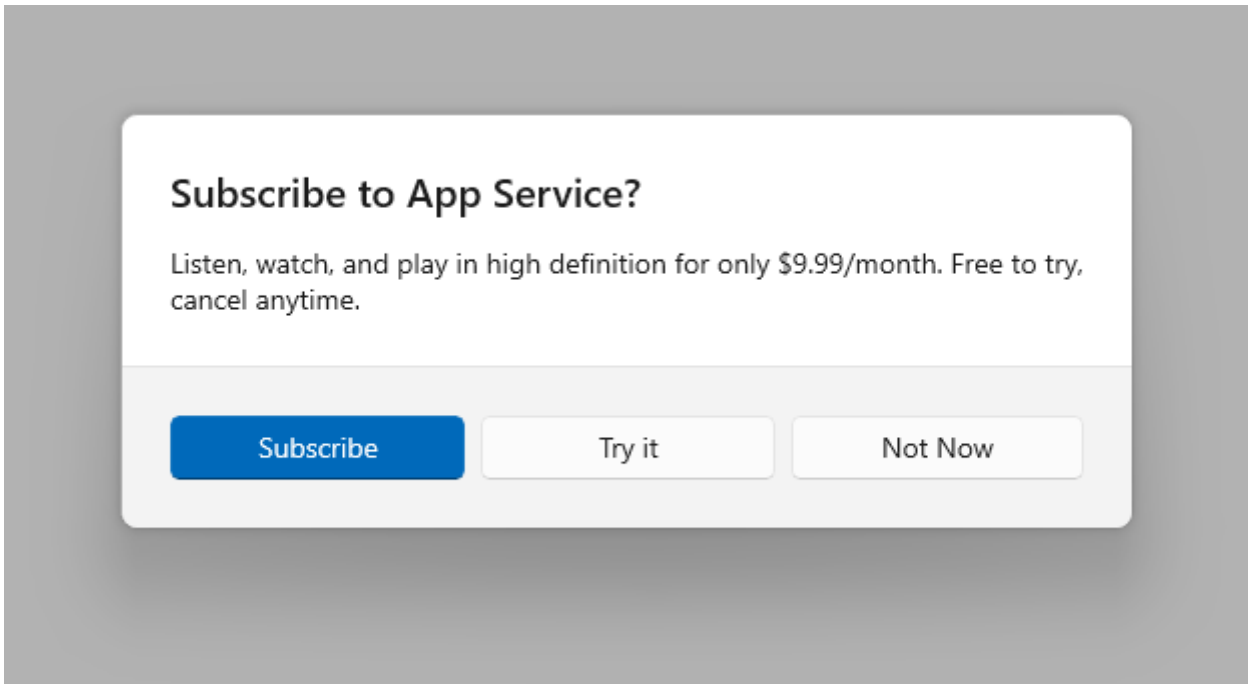


DefaultButton

You may optionally choose to differentiate one of the three buttons as the default button. Specifying the default button causes the following to happen:

- The button receives the Accent Button visual treatment
- The button will respond to the ENTER key automatically
  - When the user presses the ENTER key on the keyboard, the click handler associated with the Default Button will fire and the ContentDialogResult will return the value associated with the Default Button
  - If the user has placed Keyboard Focus on a control that handles ENTER, the Default Button will not respond to ENTER presses
- The button will receive focus automatically when the Dialog is opened unless the dialog's content contains focusable UI

Use the ContentDialog.DefaultButton property to indicate the default button. By default, no default button is set.



C#

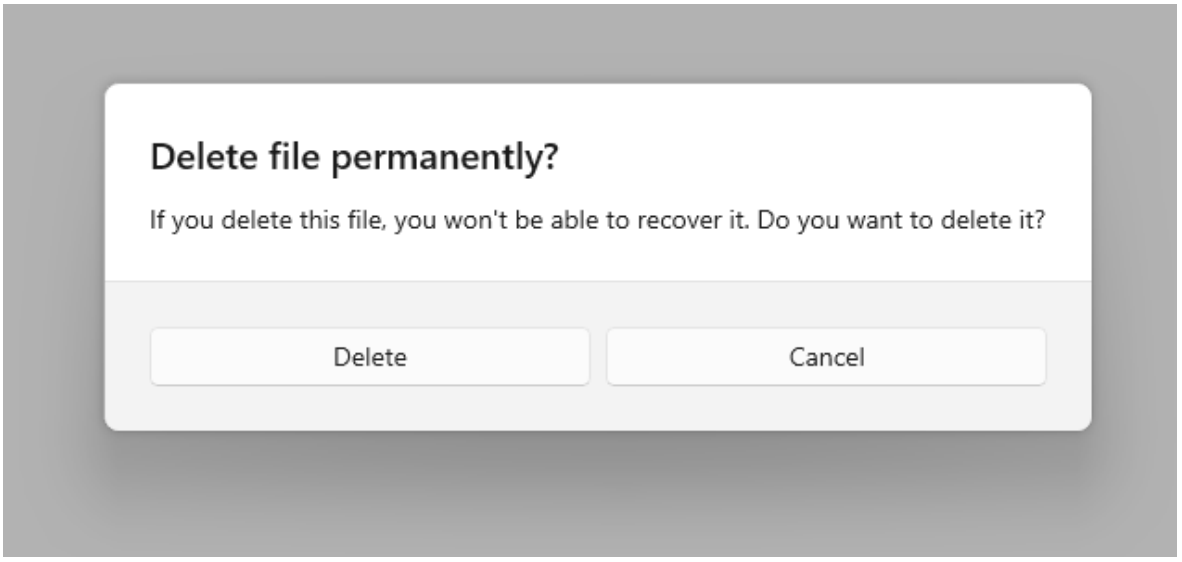
```
private async void DisplaySubscribeDialog()
{
    ContentDialog subscribeDialog = new ContentDialog
    {
        Title = "Subscribe to App Service?",
        Content = "Listen, watch, and play in high definition for only
$9.99/month. Free to try, cancel anytime.",
        CloseButtonText = "Not Now",
        PrimaryButtonText = "Subscribe",
        SecondaryButtonText = "Try it",
        DefaultButton = ContentDialogButton.Primary
    };

    ContentDialogResult result = await subscribeDialog.ShowAsync();
}
```

Confirmation dialogs (OK/Cancel)

A confirmation dialog gives users the chance to confirm that they want to perform an action. They can affirm the action, or choose to cancel. A typical confirmation dialog has two buttons: an affirmation ("OK") button and a cancel button.

- In general, the affirmation button should be on the left (the primary button) and the cancel button (the secondary button) should be on the right.



- As noted in the general recommendations section, use buttons with text that identifies specific responses to the main instruction or content.

> Some platforms put the affirmation button on the right instead of the left. So why do we recommend putting it on the left? If you assume that the majority of users are right-handed and they hold their phone with that hand, it's actually more comfortable to press the affirmation button when it's on the left, because the button is more likely to be within the user's thumb-arc. Buttons on the right-side of the screen require the user to pull their thumb inward into a less-comfortable position.

ContentDialog in AppWindow or Xaml Islands

> NOTE: This section applies only to apps that target Windows 10, version 1903 or later. AppWindow and XAML Islands are not available in earlier versions. For more info about versioning, see Version adaptive apps.

By default, content dialogs display modally relative to the root ApplicationView. When you use ContentDialog inside of either an AppWindow or a XAML Island, you need to manually set the XamlRoot on the dialog to the root of the XAML host.

To do so, set the ContentDialog's XamlRoot property to the same XamlRoot as an element already in the AppWindow or XAML Island, as shown here.

C#

```
private async void DisplayNoWifiDialog()
{
    ContentDialog noWifiDialog = new ContentDialog
    {
        Title = "No wifi connection",
```

```
        Content = "Check your connection and try again.",
        CloseButtonText = "OK"
    };

    // Use this code to associate the dialog to the appropriate AppWindow by
setting
    // the dialog's XamlRoot to the same XamlRoot as an element that is
already present in the AppWindow.
    if
(ApiInformation.IsApiContractPresent("Windows.Foundation.UniversalApiContrac
t", 8))
    {
        noWifiDialog.XamlRoot = elementAlreadyInMyAppWindow.XamlRoot;
    }

    ContentDialogResult result = await noWifiDialog.ShowAsync();
}
```

> **⚠ Warning**
>
> There can only be one ContentDialog open per thread at a time. Attempting to open two ContentDialogs will throw an exception, even if they are attempting to open in separate AppWindows.

UWP and WinUI 2

> **ⓘ Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

APIs for this control exist in the Windows.UI.Xaml.Controls namespace.

- ✓ **UWP APIs:** ContentDialog class
- ✓ Open the WinUI 2 Gallery app and see the ContentDialog in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles and templates for all controls. WinUI 2.2 or later includes a new template for this control that uses rounded corners. For more info, see Corner radius.

Flyouts

Article • 02/26/2025

A flyout is a light dismiss container that can show arbitrary UI as its content. Flyouts can contain other flyouts or context menus to create a nested experience.

Is this the right control?

- Don't use a flyout instead of tooltip or context menu. Use a tooltip to show a short description that hides after a specified time. Use a context menu for contextual actions related to a UI element, such as copy and paste.

For recommendations on when to use a flyout vs. when to use a dialog (a similar control), see Dialogs and flyouts.

Create a flyout

✓ **Important APIs**: Flyout class, Button.Flyout property

Open the WinUI 3 Gallery app and see the Flyout in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

Flyouts are attached to specific controls. You can use the Placement property to specify where a flyout appears: Top, Left, Bottom, Right, or Full. If you select the Full placement mode, the app stretches the flyout and centers it inside the app window. Some controls, such as Button, provide a Flyout property that you can use to associate a flyout or context menu.

This example creates a simple flyout that displays some text when the button is pressed.

XAML

```
<Button Content="Click me">
  <Button.Flyout>
     <Flyout>
        <TextBlock Text="This is a flyout!"/>
     </Flyout>
```

```
  </Button.Flyout>
</Button>
```

If the control doesn't have a flyout property, you can use the FlyoutBase.AttachedFlyout attached property instead. When you do this, you also need to call the FlyoutBase.ShowAttachedFlyout method to show the flyout.

This example adds a simple flyout to an image. When the user taps the image, the app shows the flyout.

XAML

```
<Image Source="Assets/cliff.jpg" Width="50" Height="50"
  Margin="10" Tapped="Image_Tapped">
  <FlyoutBase.AttachedFlyout>
    <Flyout>
      <TextBlock Text="This is some text in a flyout."  />
    </Flyout>
  </FlyoutBase.AttachedFlyout>
</Image>
```

C#

```
private void Image_Tapped(object sender, TappedRoutedEventArgs e)
{
    FlyoutBase.ShowAttachedFlyout((FrameworkElement)sender);
}
```

The previous examples defined their flyouts inline. You can also define a flyout as a static resource and then use it with multiple elements. This example creates a more complicated flyout that displays a larger version of an image when its thumbnail is tapped.

XAML

```
<!-- Declare the shared flyout as a resource. -->
<Page.Resources>
    <Flyout x:Key="ImagePreviewFlyout" Placement="Right">
        <!-- The flyout's DataContext must be the Image Source
             of the image the flyout is attached to. -->
        <Image Source="{Binding Path=Source}"
            MaxHeight="400" MaxWidth="400" Stretch="Uniform"/>
    </Flyout>
</Page.Resources>
```

XAML

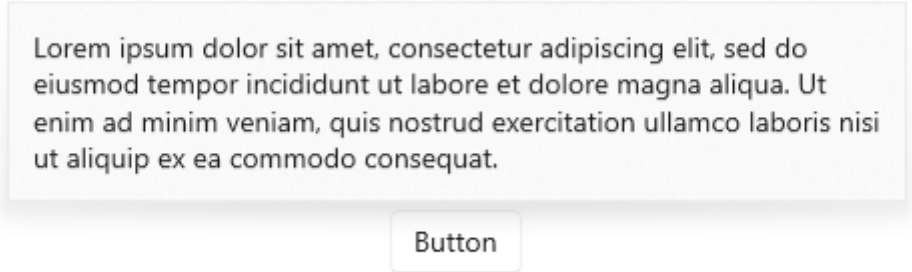
```
<!-- Assign the flyout to each element that shares it. -->
<StackPanel>
    <Image Source="Assets/cliff.jpg" Width="50" Height="50"
           Margin="10" Tapped="Image_Tapped"
           FlyoutBase.AttachedFlyout="{StaticResource ImagePreviewFlyout}"
           DataContext="{Binding RelativeSource={RelativeSource
Mode=Self}}"/>
    <Image Source="Assets/grapes.jpg" Width="50" Height="50"
           Margin="10" Tapped="Image_Tapped"
           FlyoutBase.AttachedFlyout="{StaticResource ImagePreviewFlyout}"
           DataContext="{Binding RelativeSource={RelativeSource
Mode=Self}}"/>
    <Image Source="Assets/rainier.jpg" Width="50" Height="50"
           Margin="10" Tapped="Image_Tapped"
           FlyoutBase.AttachedFlyout="{StaticResource ImagePreviewFlyout}"
           DataContext="{Binding RelativeSource={RelativeSource
Mode=Self}}"/>
</StackPanel>
```

C#

```
private void Image_Tapped(object sender, TappedRoutedEventArgs e)
{
    FlyoutBase.ShowAttachedFlyout((FrameworkElement)sender);
}
```

Style a flyout

To style a Flyout, modify its FlyoutPresenterStyle. This example shows a paragraph of wrapping text and makes the text block accessible to a screen reader.



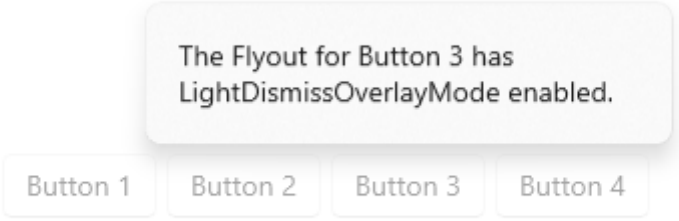
XAML

```
<Flyout>
  <Flyout.FlyoutPresenterStyle>
    <Style TargetType="FlyoutPresenter">
```

```
      <Setter Property="ScrollViewer.HorizontalScrollMode"
          Value="Disabled"/>
      <Setter Property="ScrollViewer.HorizontalScrollBarVisibility"
Value="Disabled"/>
      <Setter Property="IsTabStop" Value="True"/>
      <Setter Property="TabNavigation" Value="Cycle"/>
    </Style>
  </Flyout.FlyoutPresenterStyle>
  <TextBlock Style="{StaticResource BodyTextBlockStyle}" Text="Lorem ipsum
dolor sit amet, consectetur adipiscing elit, sed do eiusmod tempor
incididunt ut labore et dolore magna aliqua. Ut enim ad minim veniam, quis
nostrud exercitation ullamco laboris nisi ut aliquip ex ea commodo
consequat."/>
</Flyout>
```

Styling flyouts for 10-foot experiences

Light dismiss controls like flyout trap keyboard and gamepad focus inside their transient UI until dismissed. To provide a visual cue for this behavior, light dismiss controls on Xbox draw an overlay that dims the contrast and visibility of out of scope UI. This behavior can be modified with the LightDismissOverlayMode property. By default, flyouts will draw the light dismiss overlay on Xbox but not other device families, but apps can choose to force the overlay to be always **On** or always **Off**.



XAML

```
<MenuFlyout LightDismissOverlayMode="On">
```

Light dismiss behavior

Flyouts can be closed with a quick light dismiss action, including

- Tap outside the flyout
- Press the Escape keyboard key

- Press the hardware or software system Back button
- Press the gamepad B button

When dismissing with a tap, this gesture is typically absorbed and not passed on to the UI underneath. For example, if there's a button visible behind an open flyout, the user's first tap dismisses the flyout but does not activate this button. Pressing the button requires a second tap.

You can change this behavior by designating the button as an input pass-through element for the flyout. The flyout will close as a result of the light dismiss actions described above and will also pass the tap event to its designated `OverlayInputPassThroughElement`. Consider adopting this behavior to speed up user interactions on functionally similar items. If your app has a favorites collection and each item in the collection includes an attached flyout, it's reasonable to expect that users may want to interact with multiple flyouts in rapid succession.

> **Note**
>
> Be careful not to designate an overlay input pass-through element which results in a destructive action. Users have become habituated to discreet light dismiss actions which do not activate primary UI. Close, Delete, or similarly destructive buttons should not activate on light dismiss to avoid unexpected and disruptive behavior.

In the following example, all three buttons inside FavoritesBar will be activated on the first tap.

XAML

```
<Page>
    <Page.Resources>
        <Flyout x:Name="TravelFlyout" x:Key="TravelFlyout"
                OverlayInputPassThroughElement="{x:Bind FavoritesBar}">
            <StackPanel>
                <HyperlinkButton Content="Washington Trails Association"/>
                <HyperlinkButton Content="Washington Cascades - Go
Northwest! A Travel Guide"/>
            </StackPanel>
        </Flyout>
    </Page.Resources>

    <Grid>
        <Grid.RowDefinitions>
            <RowDefinition Height="Auto"/>
            <RowDefinition Height="*"/>
        </Grid.RowDefinitions>
        <StackPanel x:Name="FavoritesBar" Orientation="Horizontal">
```

```
            <HyperlinkButton x:Name="PageLinkBtn">Bing</HyperlinkButton>
            <Button x:Name="Folder1" Content="Travel" Flyout="
{StaticResource TravelFlyout}"/>
            <Button x:Name="Folder2" Content="Entertainment"
Click="Folder2_Click"/>
        </StackPanel>
        <ScrollViewer Grid.Row="1">
            <WebView x:Name="WebContent"/>
        </ScrollViewer>
    </Grid>
</Page>
```

C#

```
private void Folder2_Click(object sender, RoutedEventArgs e)
{
     Flyout flyout = new Flyout();
     flyout.OverlayInputPassThroughElement = FavoritesBar;
     ...
     flyout.ShowAt(sender as FrameworkElement);
{
```

UWP and WinUI 2

> **ⓘ Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

APIs for this control exist in the Windows.UI.Xaml.Controls namespace.

- ✓ **UWP APIs:** Flyout class, Button.Flyout property
- ✓ Open the WinUI 2 Gallery app and see the Flyout in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles and templates for all controls. WinUI 2.2 or later includes a new template for this control that uses

rounded corners. For more info, see Corner radius.

Teaching tip

Article • 02/26/2025

A teaching tip is a semi-persistent and content-rich flyout that provides contextual information. It is often used for informing, reminding, and teaching users about important and new features that may enhance their experience.

A teaching tip may be light-dismiss or require explicit action to close. A teaching tip can target a specific UI element with its tail and also be used without a tail or target.

Is this the right control?

Use a **TeachingTip** control to focus a user's attention on new or important updates and features, remind a user of nonessential options that would improve their experience, or teach a user how a task should be completed.

Because teaching tip is transient, it would not be the recommended control for prompting users about errors or important status changes.

Recommendations

- Tips are impermanent and should not contain information or options that are critical to the experience of an application.
- Try to avoid showing teaching tips too often. Teaching tips are most likely to each receive individual attention when they are staggered throughout long sessions or across multiple sessions.
- Keep tips succinct and their topic clear. Research shows users, on average, only read 3-5 words and only comprehend 2-3 words before deciding whether to interact with a tip.
- Gamepad accessibility of a teaching tip is not guaranteed. For applications that predict gamepad input, please see gamepad and remote control interactions. It is encouraged to test gamepad accessibility of each teaching tip using all possible configurations of an app's UI.
- When enabling a teaching tip to escape the xaml root, it is encouraged to also enable the IsLightDismissEnabled property and set the PreferredPlacement mode nearest to the center of the xaml root.

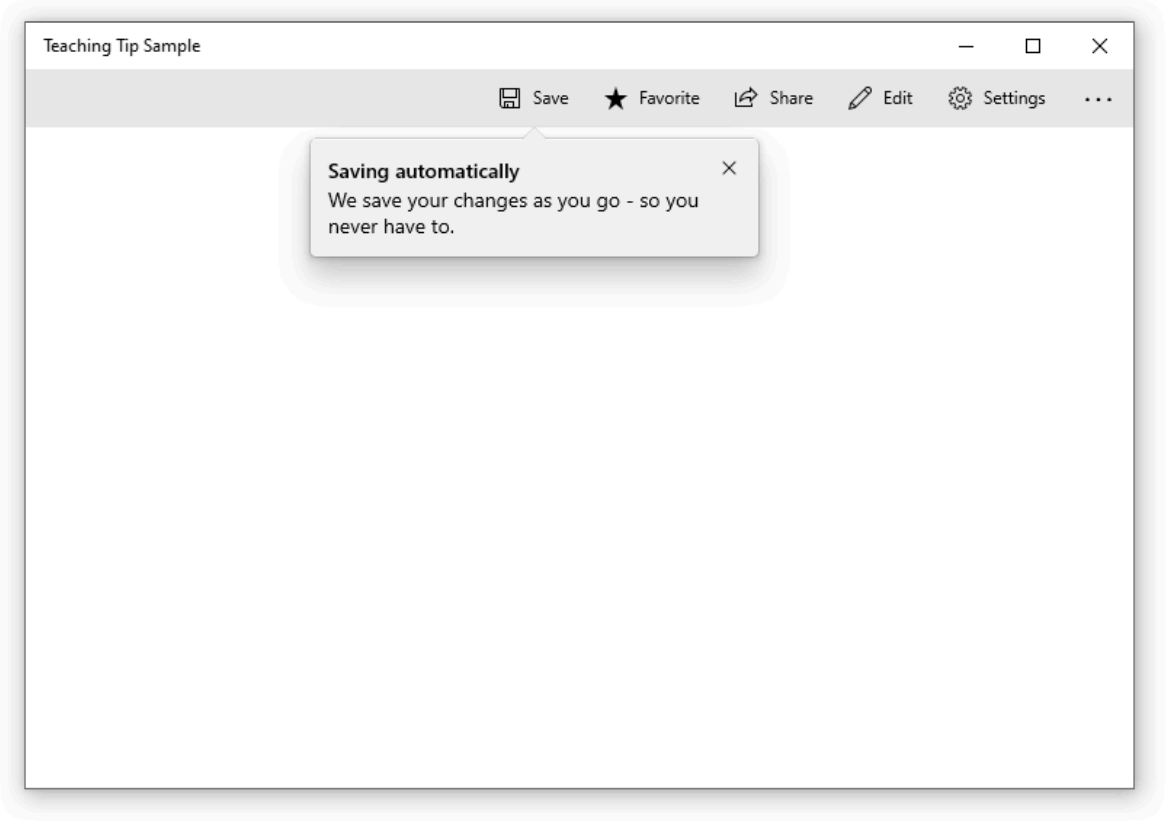
Reconfiguring an open teaching tip

Some content and properties can be reconfigured while the teaching tip is open and will take effect immediately. Other content and properties, such as the icon property, the Action and Close buttons, and reconfiguring between light-dismiss and explicit-dismiss will all require the teaching tip to be closed and reopened for changes to these properties to take affect. Note that changing dismissal behavior from manual-dismiss to light-dismiss while a teaching tip is open will cause the teaching tip to have its Close button removed before the light-dismiss behavior is enabled and the tip can remain stuck on-screen.

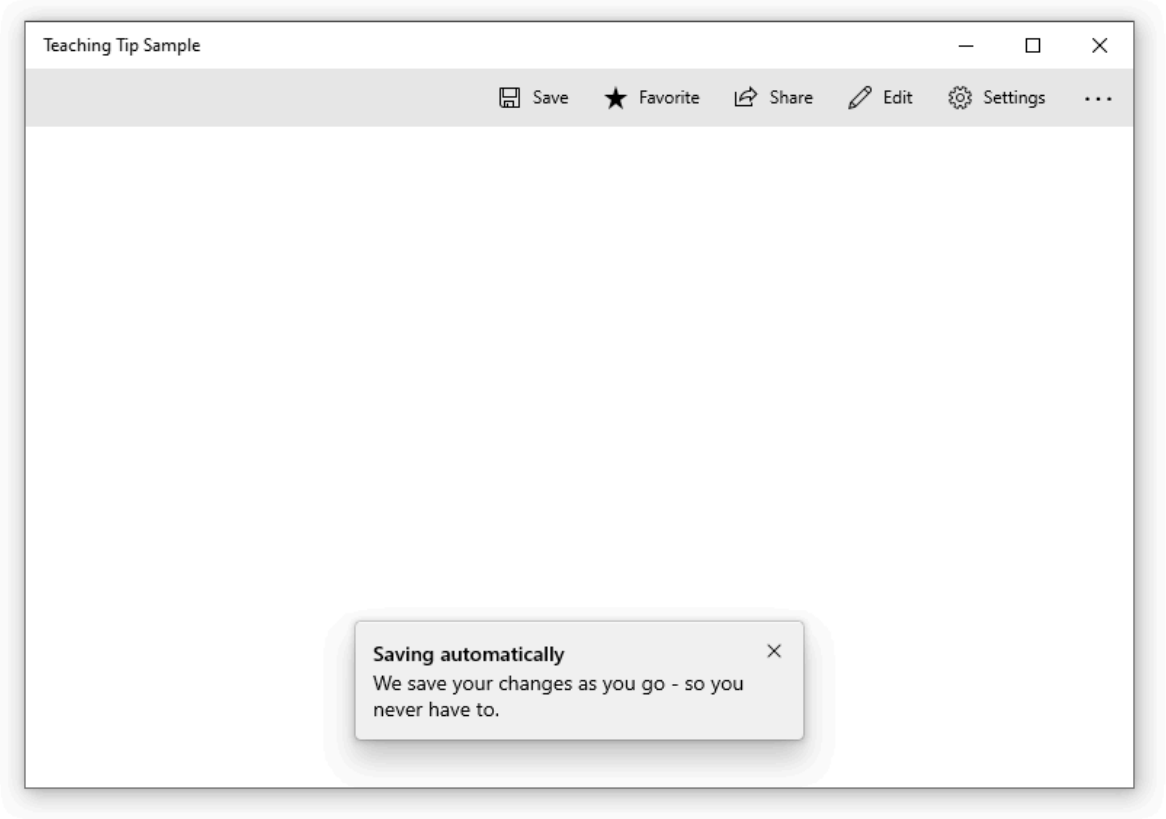
Examples

A teaching tip can have several configurations, including these notable ones:

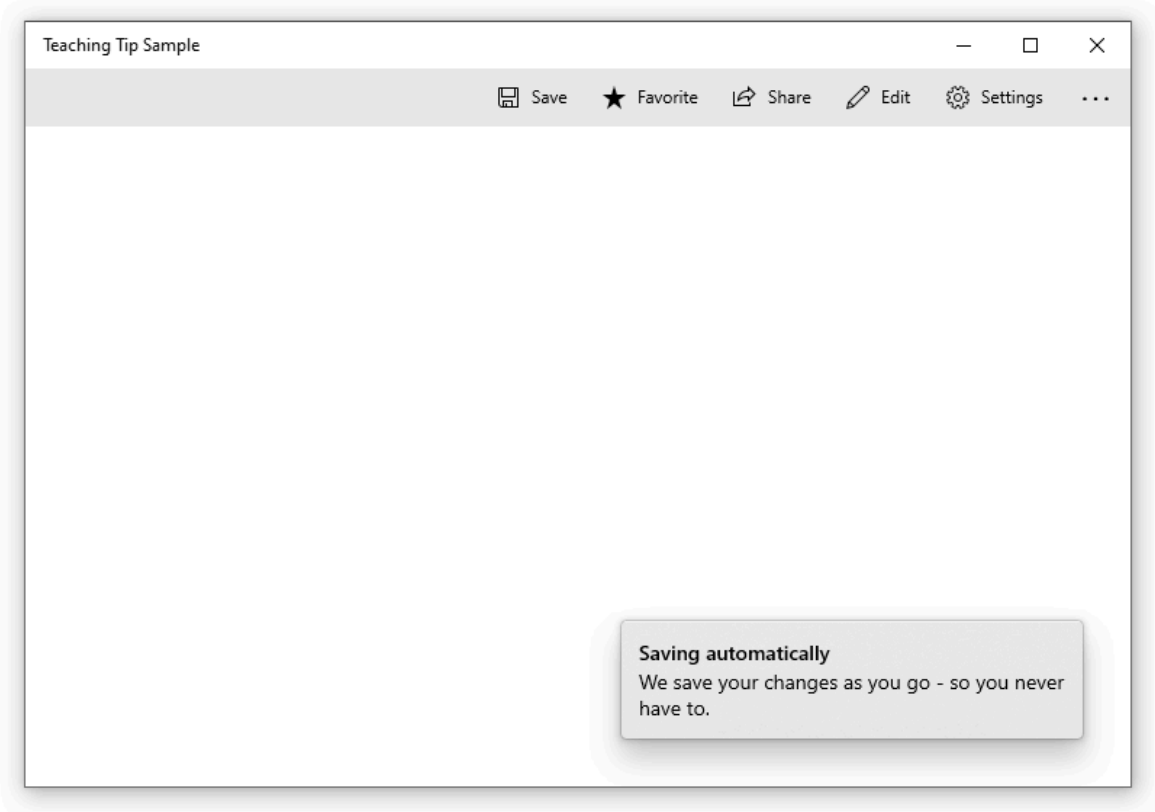
A teaching tip can target a specific UI element with its tail to enhance contextual clarity of the information it is presenting.



When the information presented does not pertain to a particular UI element, a nontargeted teaching tip can be created by removing the tail.



A teaching tip can require the user to dismiss it via an "X" button in a top corner or a "Close" button at the bottom. A teaching tip may also be light-dismiss enabled in which case there is no dismiss button and the teaching tip will instead dismiss when a user scrolls or interacts with other elements of the application. Because of this behavior, light-dismiss tips are the best solution when a tip needs to be placed in a scrollable area.



Create a teaching tip

✔ **Important APIs:** TeachingTip class

Open the WinUI 3 Gallery app and see the TeachingTip in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

Here's the XAML for a targeted teaching tip control that demonstrates the default look of the TeachingTip with a title and subtitle. Note that the teaching tip can appear anywhere in the element tree or code behind. In this example below, it's located in a ResourceDictionary.

XAML

```
<Button x:Name="SaveButton" Content="Save">
    <Button.Resources>
        <TeachingTip x:Name="AutoSaveTip"
            Target="{x:Bind SaveButton}"
            Title="Save automatically"
            Subtitle="When you save your file to OneDrive, we save your
changes as you go - so you never have to.">
```

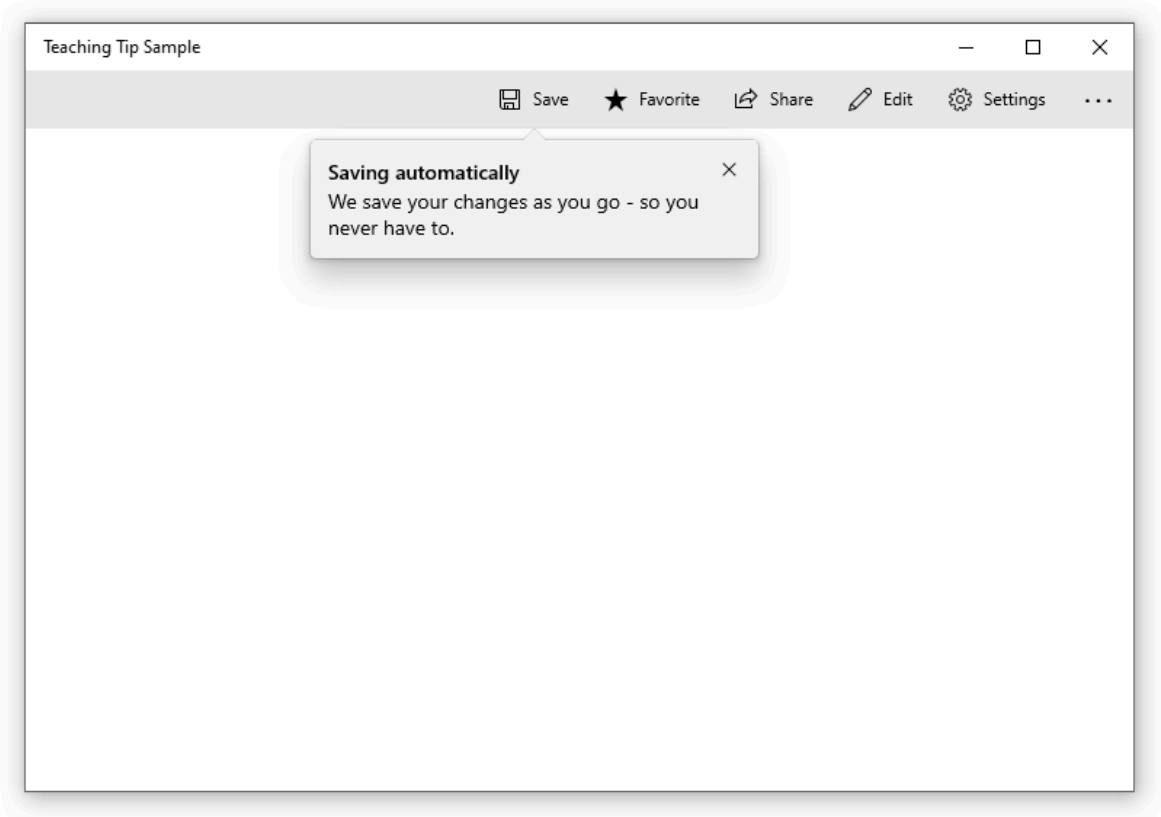
```
        </TeachingTip>
    </Button.Resources>
</Button>
```

C#

```
public MainPage()
{
    this.InitializeComponent();

    if(!HaveExplainedAutoSave())
    {
        AutoSaveTip.IsOpen = true;
        SetHaveExplainedAutoSave();
    }
}
```

Here's the result when the Page containing the button and teaching tip is shown:



In the example above, the Title and Subtitle properties are used to set the teaching tip's title and subtitle. The Target property is set to the "SaveButton" to establish the visual connection between itself and the button. To show the teaching tip, its IsOpen property is set to `true`.

Non-targeted tips

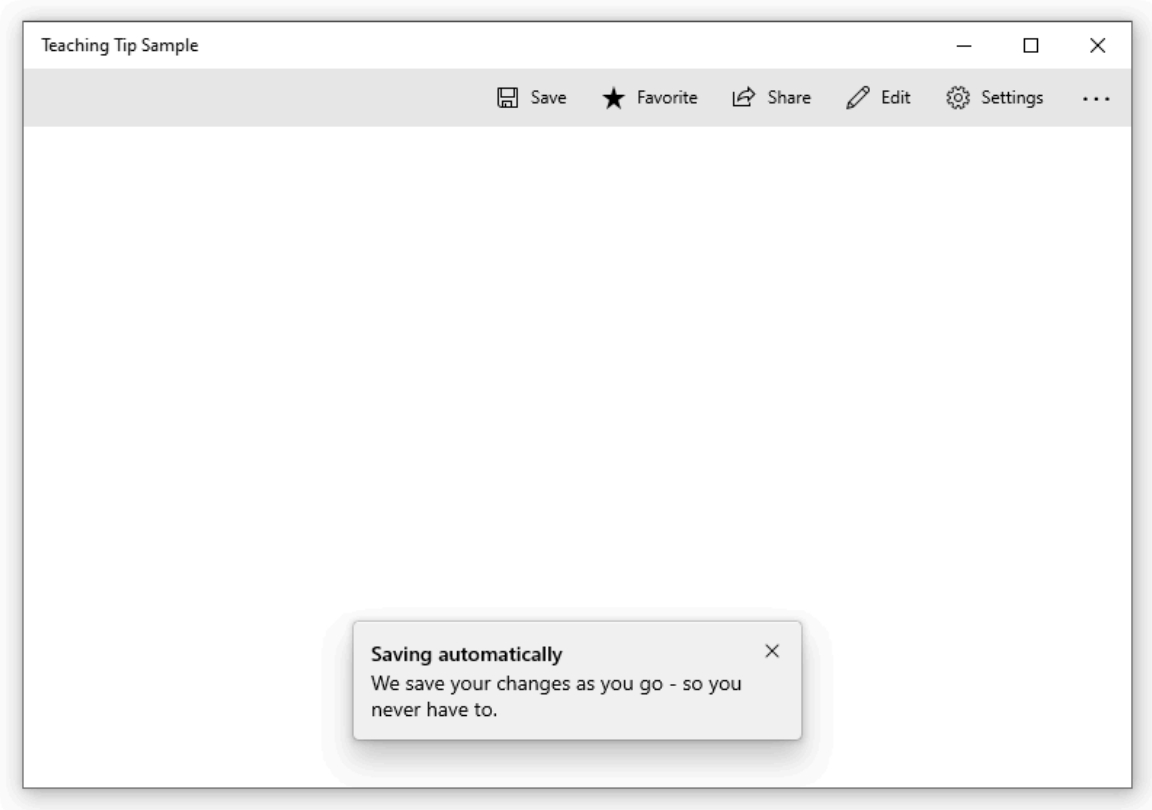
Not all tips relate to an element onscreen. For these scenarios, do not set a target and the teaching tip will instead display relative to the edges of the xaml root. However, a teaching tip can have the tail removed while retaining placement relative to a UI element by setting the TailVisibility property to "Collapsed". The following example is of a non-targeted teaching tip.

XAML

```
<Button x:Name="SaveButton" Content="Save" />

<TeachingTip x:Name="AutoSaveTip"
    Title="Saving automatically"
    Subtitle="We save your changes as you go - so you never have to.">
</TeachingTip>
```

Note that in this example the TeachingTip is in the element tree rather than in a ResourceDictionary or in code behind. This has no effect on behavior; the TeachingTip only displays when opened, and takes up no layout space.



Preferred placement

Teaching tip replicates Flyout's FlyoutPlacementMode placement behavior with the PreferredPlacement property. The default placement mode will try to place a targeted

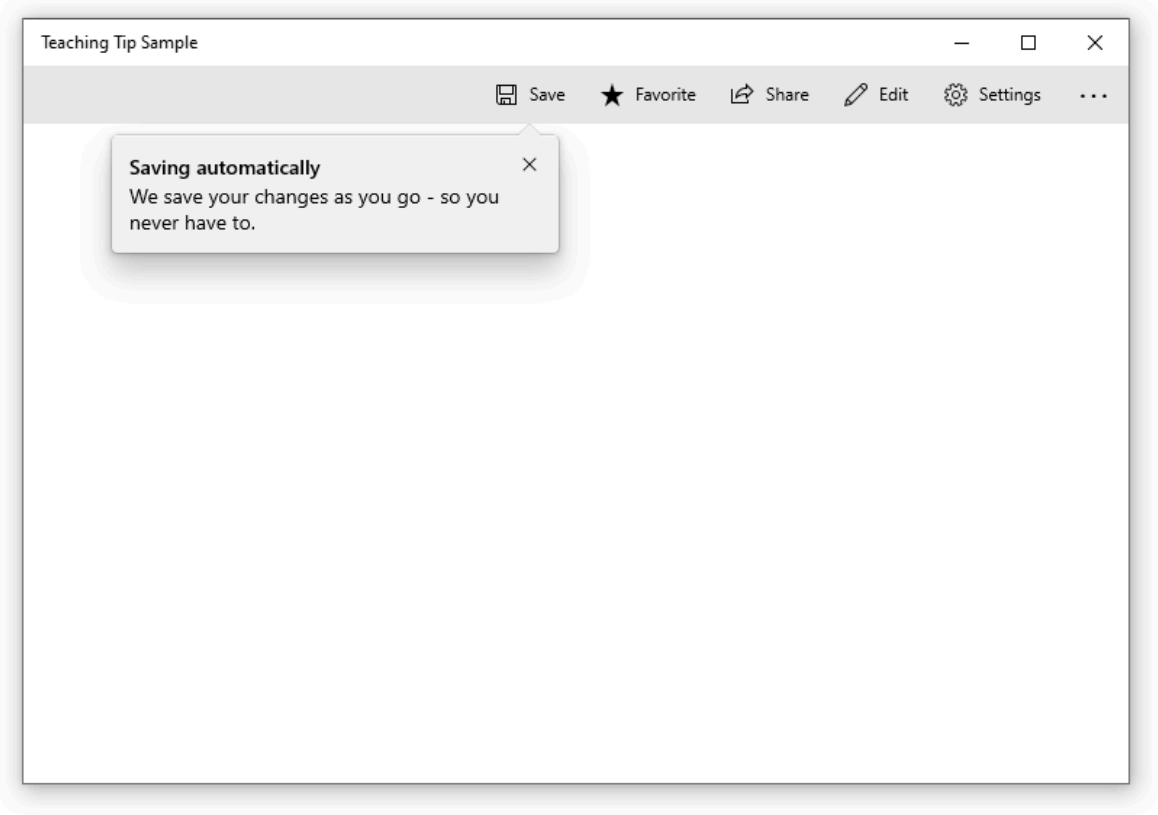
teaching tip above its target and a non-targeted teaching tip centered at the bottom of the xaml root. As with Flyout, if the preferred placement mode would not leave room for the teaching tip to show, another placement mode will be automatically chosen.

For applications that predict gamepad input, please see gamepad and remote control interactions. It is encouraged to test gamepad accessibility of each teaching tip using all possible configurations of an app's UI.

A targeted teaching tip with its PreferredPlacement set to "BottomLeft" will appear with the tail centered at the bottom of its target with the teaching tip's body shifted toward the left.

XAML

```
<Button x:Name="SaveButton" Content="Save">
    <Button.Resources>
        <TeachingTip x:Name="AutoSaveTip"
            Target="{x:Bind SaveButton}"
            Title="Saving automatically"
            Subtitle="We save your changes as you go - so you never have
to."
            PreferredPlacement="BottomLeft">
        </TeachingTip>
    </Button.Resources>
</Button>
```

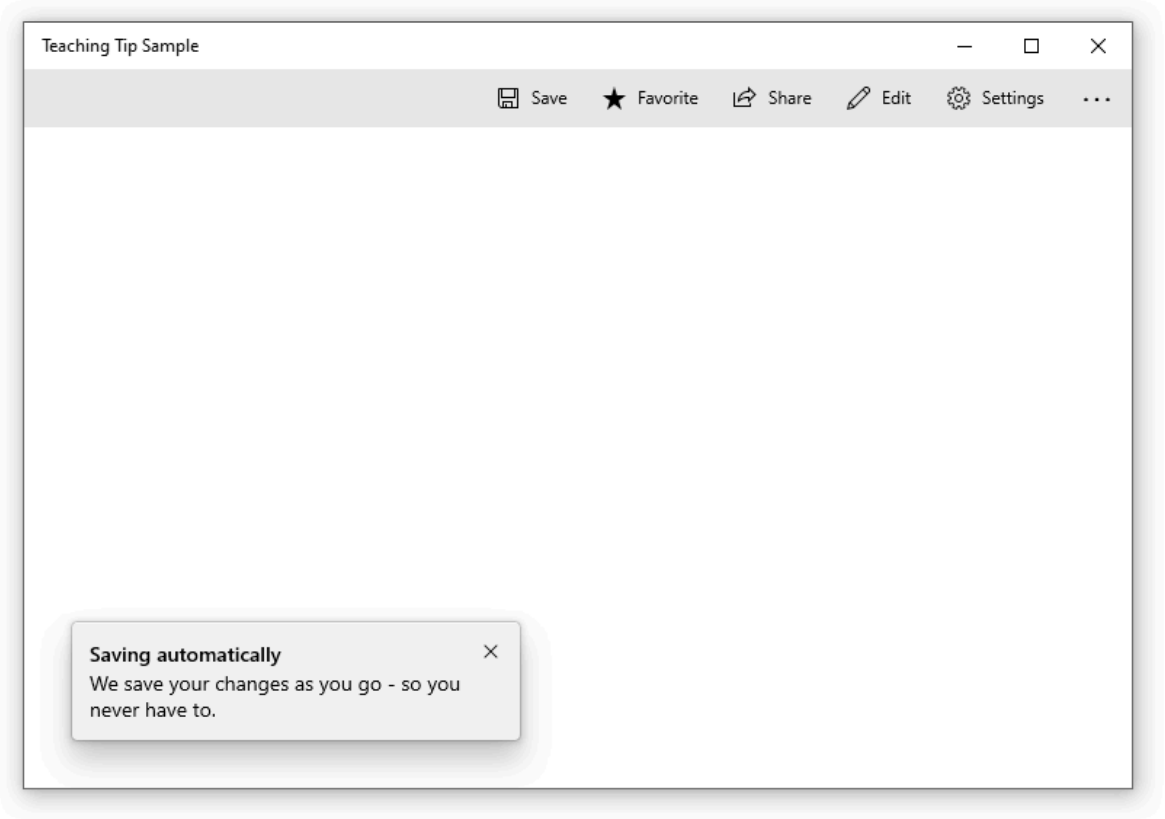


A non-targeted teaching tip with its PreferredPlacement set to "BottomLeft" will appear in the bottom left corner of the xaml root.

XAML

```
<Button x:Name="SaveButton" Content="Save" />

<TeachingTip x:Name="AutoSaveTip"
    Title="Saving automatically"
    Subtitle="We save your changes as you go - so you never have to."
    PreferredPlacement="BottomLeft">
</TeachingTip>
```



The diagram below depicts the result of all 13 PreferredPlacement modes that can be set for targeted teaching tips.

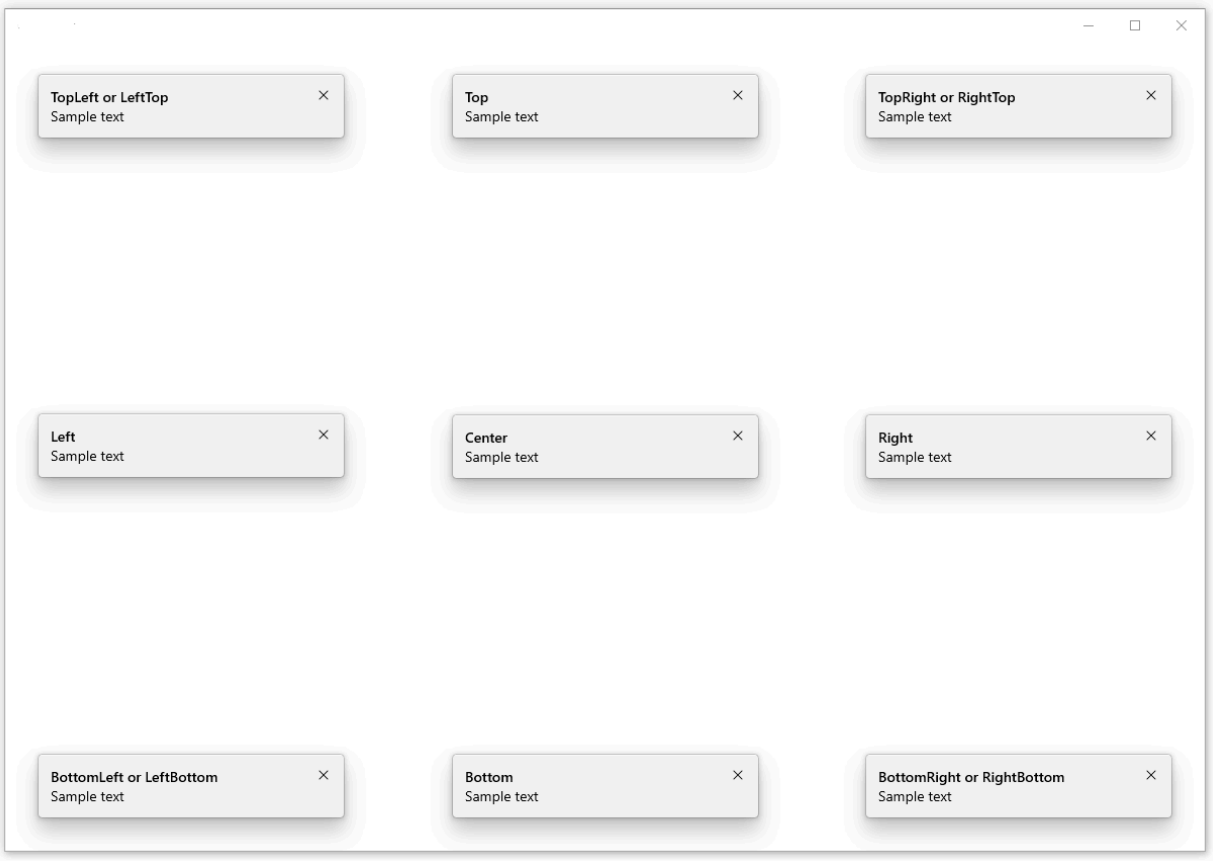
Center
Sample text
Button

The diagram below depicts the result of all 13 PreferredPlacement modes that can be set for non-targeted teaching tips.



Add a placement margin

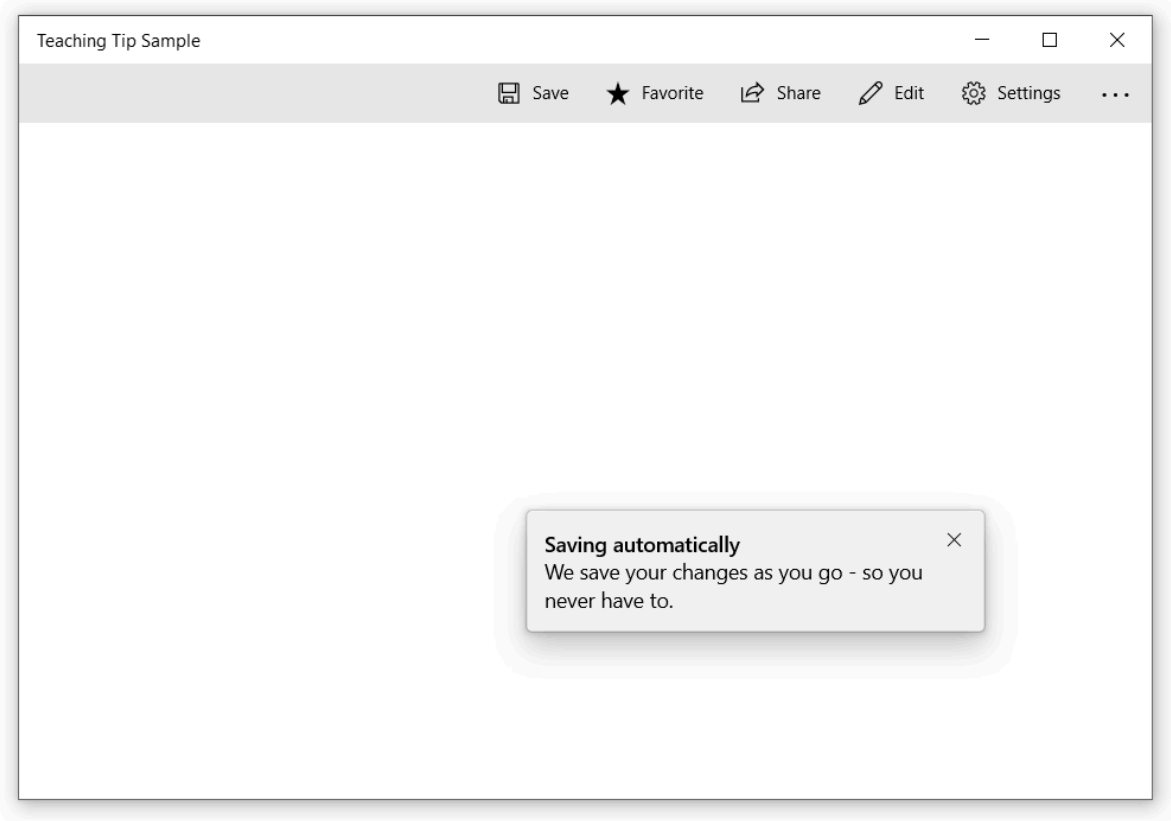
You can control how far a targeted teaching tip is set apart from its target and how far a non-targeted teaching tip is set apart from the edges of the xaml root by using the PlacementMargin property. Like Margin, PlacementMargin has four values – left, right, top, and bottom – so only the relevant values are used. For example, PlacementMargin.Left applies when the tip is left of the target or on the left edge of the xaml root.

The following example shows a non-targeted tip with the PlacementMargin's Left/Top/Right/Bottom all set to 80.

XAML

```
<Button x:Name="SaveButton" Content="Save" />

<TeachingTip x:Name="AutoSaveTip"
    Title="Saving automatically"
    Subtitle="We save your changes as you go - so you never have to."
    PreferredPlacement="BottomLeft"
    PlacementMargin="80">
</TeachingTip>
```

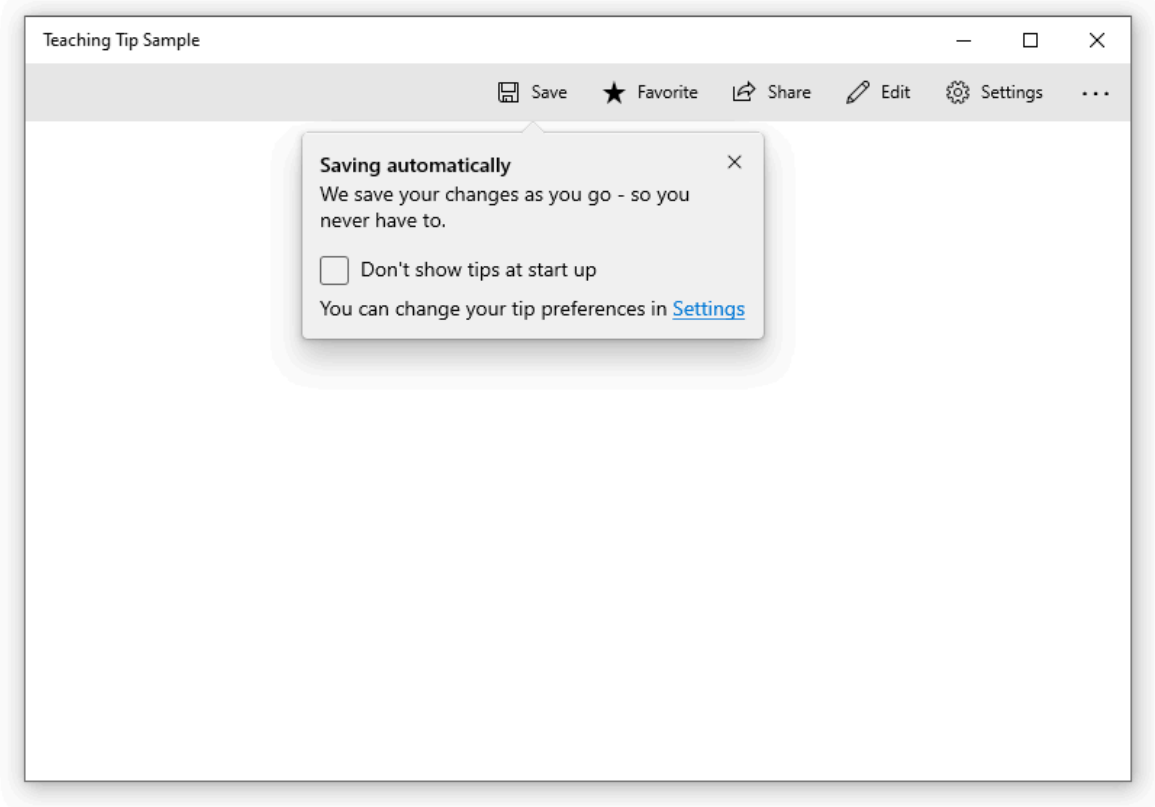


Add content

Content can be added to a teaching tip using the Content property. If there is more content to show than what the size of a teaching tip will allow, a scrollbar will be automatically enabled to allow a user to scroll the content area.

XAML

```
<Button x:Name="SaveButton" Content="Save">
    <Button.Resources>
        <TeachingTip x:Name="AutoSaveTip"
            Target="{x:Bind SaveButton}"
            Title="Saving automatically"
            Subtitle="We save your changes as you go - so you never have
to.">
                <StackPanel>
                    <CheckBox x:Name="HideTipsCheckBox" Content="Don't show
tips at start up" IsChecked="{x:Bind HidingTips, Mode=TwoWay}" />
                    <TextBlock>You can change your tip preferences in
<Hyperlink NavigateUri="app:/item/SettingsPage">Settings</Hyperlink> if you
change your mind.</TextBlock>
                </StackPanel>
        </TeachingTip>
    </Button.Resources>
</Button>
```



Add buttons

By default, a standard "X" close button is shown next to the title of a teaching tip. The Close button can be customized with the CloseButtonContent property, in which case the button is moved to the bottom of the teaching tip.

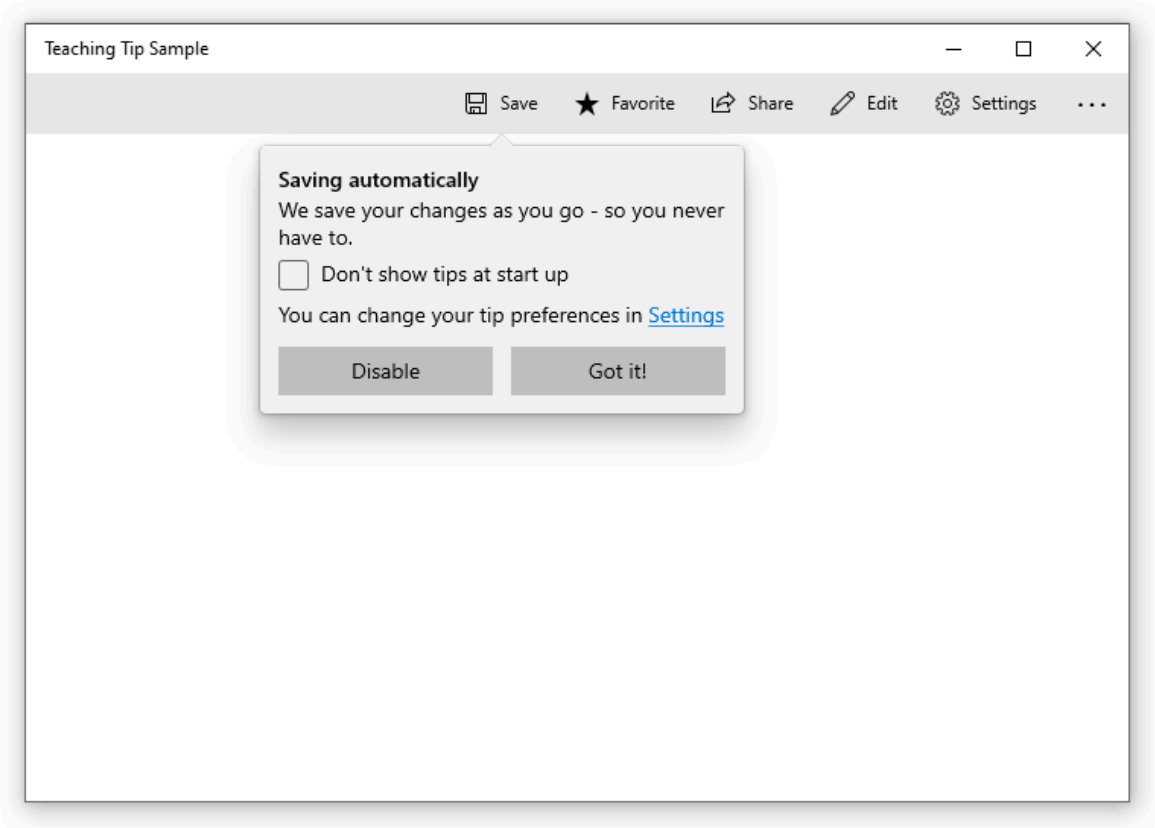
Note: No close button will appear on light-dismiss enabled tips

A custom action button can be added by setting ActionButtonContent property (and optionally the ActionButtonCommand and the ActionButtonCommandParameter properties).

XAML

```
<Button x:Name="SaveButton" Content="Save">
    <Button.Resources>
        <TeachingTip x:Name="AutoSaveTip"
            Target="{x:Bind SaveButton}"
            Title="Saving automatically"
            Subtitle="We save your changes as you go - so you never have
to."
            ActionButtonContent="Disable"
            ActionButtonCommand="{x:Bind DisableAutoSaveCommand}"
            CloseButtonContent="Got it!">
                <StackPanel>
                    <CheckBox x:Name="HideTipsCheckBox" Content="Don't show
```

```
tips at start up" IsChecked="{x:Bind HidingTips, Mode=TwoWay}" />
                    <TextBlock>You can change your tip preferences in
<Hyperlink NavigateUri="app:/item/SettingsPage">Settings</Hyperlink> if you
change your mind.</TextBlock>
                </StackPanel>
        </TeachingTip>
    </Button.Resources>
</Button>
```



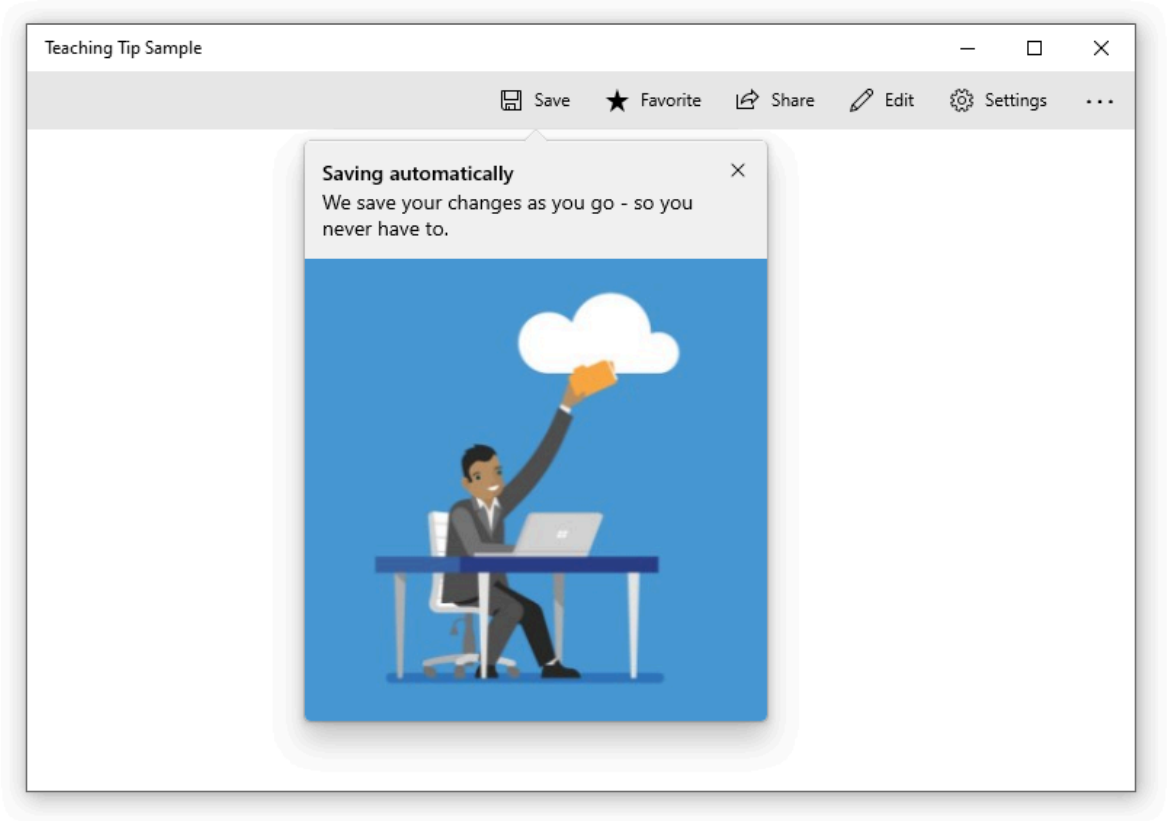
Hero content

Edge to edge content can be added to a teaching tip by setting the HeroContent property. The location of hero content can be set to the top or bottom of a teaching tip by setting the HeroContentPlacement property.

XAML

```
<Button x:Name="SaveButton" Content="Save">
    <Button.Resources>
        <TeachingTip x:Name="AutoSaveTip"
            Target="{x:Bind SaveButton}"
            Title="Saving automatically"
            Subtitle="We save your changes as you go - so you never have
to.">
            <TeachingTip.HeroContent>
                <Image Source="Assets/cloud.png" />
```

```
            </TeachingTip.HeroContent>
        </TeachingTip>
    </Button.Resources>
</Button>
```

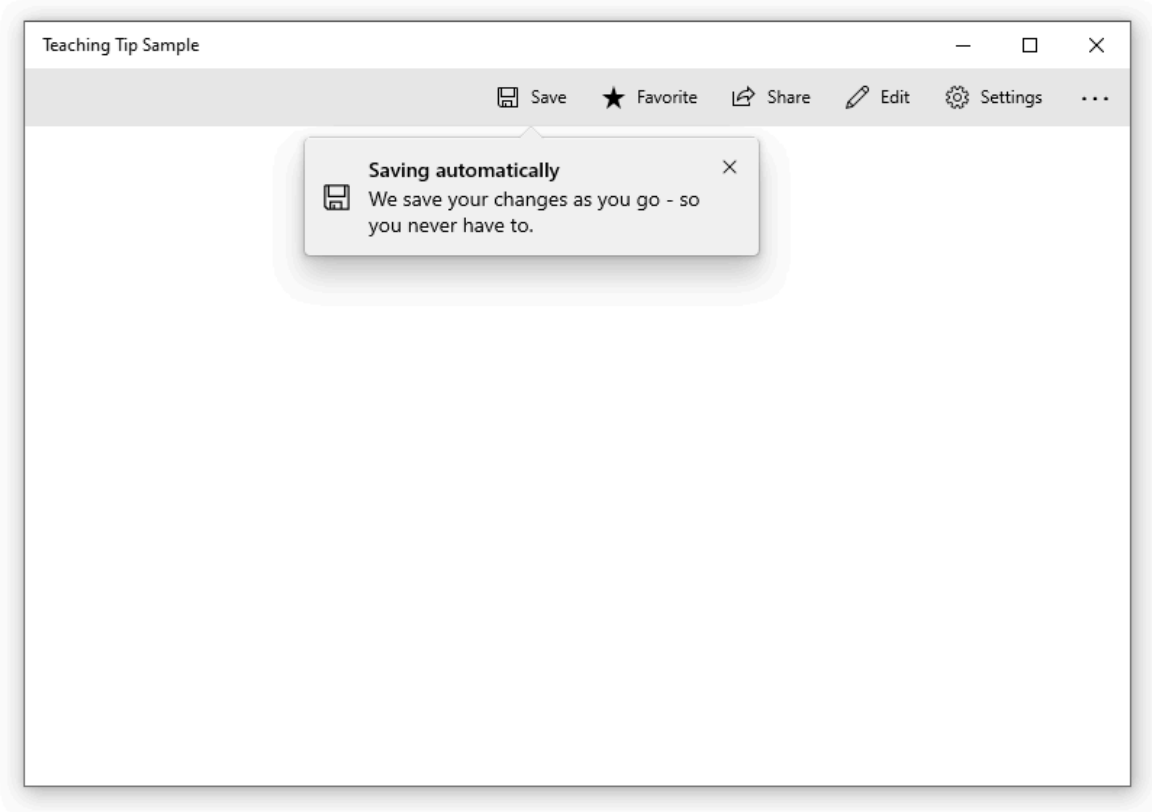


Add an icon

An icon can be added beside the title and subtitle using the IconSource property. Recommended icon sizes include 16px, 24px, and 32px.

XAML

```
<Button x:Name="SaveButton" Content="Save">
    <Button.Resources>
        <TeachingTip x:Name="AutoSaveTip"
            Target="{x:Bind SaveButton}"
            Title="Saving automatically"
            Subtitle="We save your changes as you go - so you never have
to."
            <TeachingTip.IconSource>
                <SymbolIconSource Symbol="Save" />
            </TeachingTip.IconSource>
        </TeachingTip>
    </Button.Resources>
</Button>
```



Enable light-dismiss

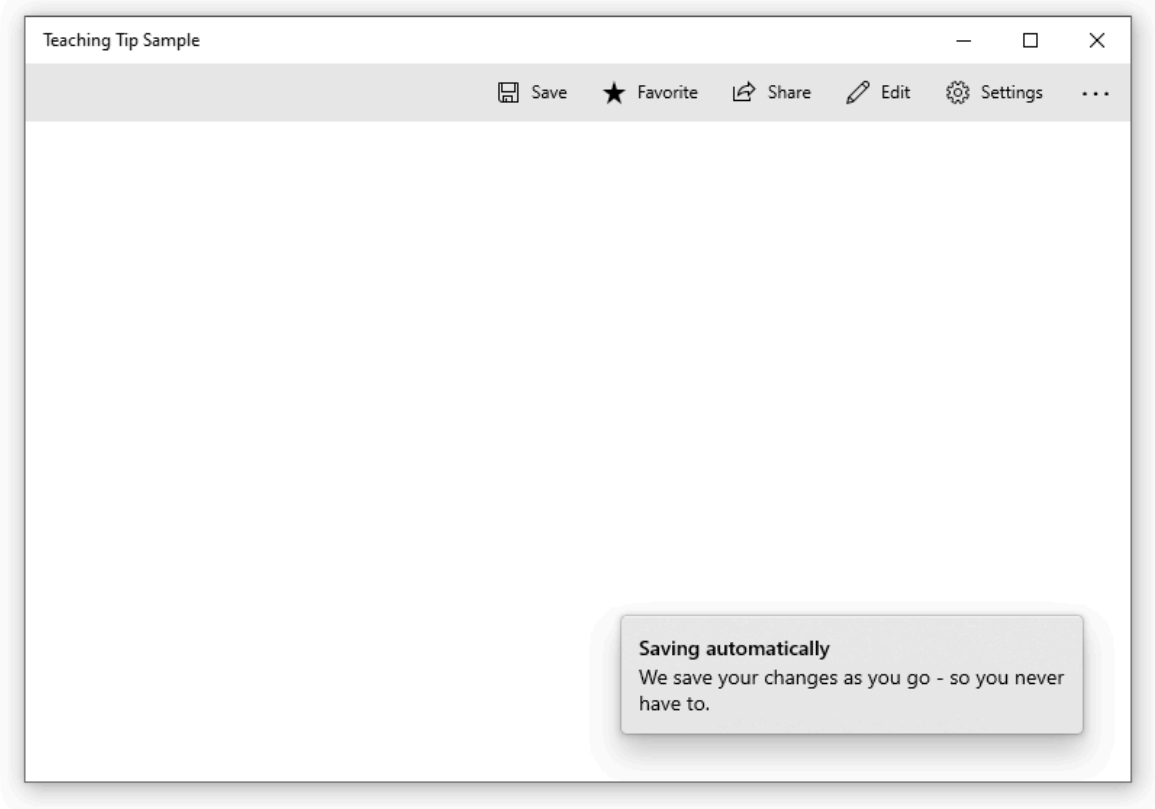
Light-dismiss functionality is disabled by default but it can enabled by setting the IsLightDismissEnabled property so that a teaching tip will dismiss, for example, when a user scrolls or interacts with other elements of the application. Because of this behavior, light-dismiss tips are the best solution when a tip needs to be placed in a scrollable area.

The close button will be automatically removed from a light-dismiss enabled teaching tip to identify its light-dismiss behavior to users.

XAML

```
<Button x:Name="SaveButton" Content="Save" />

<TeachingTip x:Name="AutoSaveTip"
    Title="Saving automatically"
    Subtitle="We save your changes as you go - so you never have to."
    IsLightDismissEnabled="True">
</TeachingTip>
```



Escaping the XAML root bounds

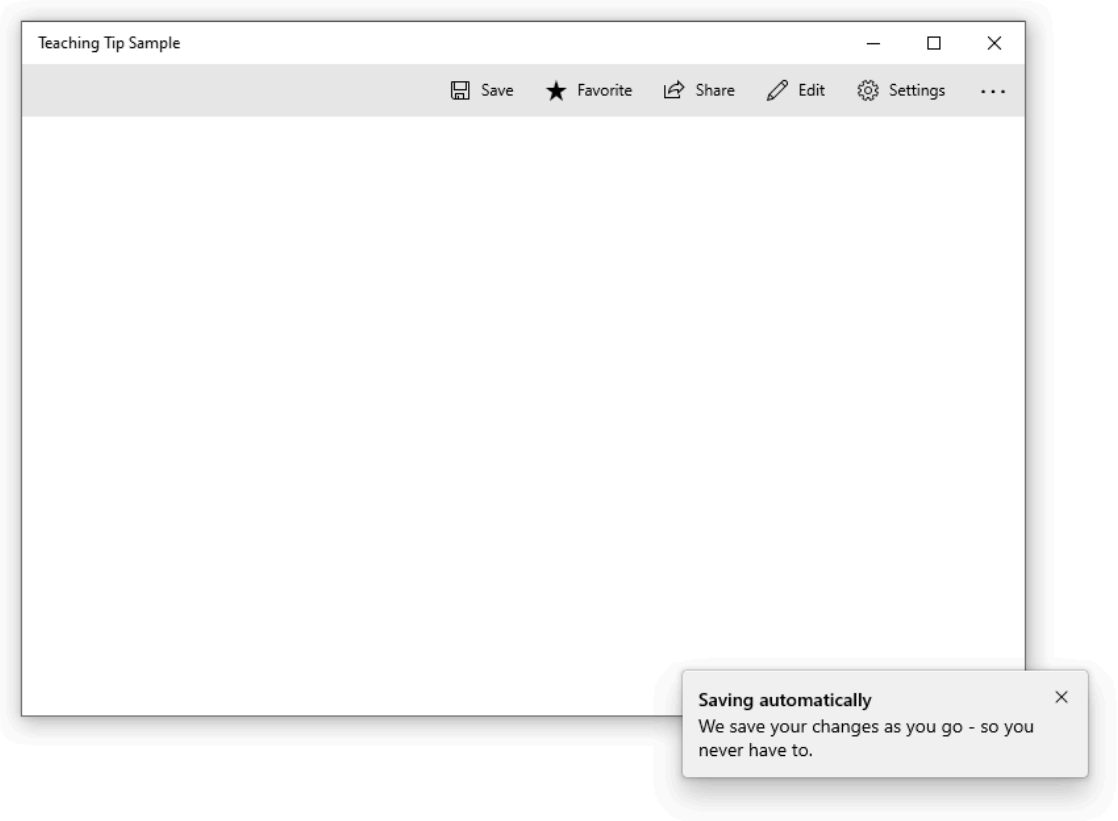
Starting with Windows 10, version 1903 (Build 18362), a teaching tip can escape the bounds of the XAML root and the screen by setting the ShouldConstrainToRootBounds property. When this property is enabled, a teaching tip will not attempt to stay in the bounds of the XAML root nor the screen and will always position at the set `PreferredPlacement` mode. It is encouraged to enable the `IsLightDismissEnabled` property and set the `PreferredPlacement` mode nearest to the center of the XAML root to ensure the best experience for users.

On earlier versions of Windows, this property is ignored and the teaching tip always stays within the bounds of the XAML root.

XAML

```
<Button x:Name="SaveButton" Content="Save" />

<TeachingTip x:Name="AutoSaveTip"
    Title="Saving automatically"
    Subtitle="We save your changes as you go - so you never have to."
    PreferredPlacement="BottomRight"
    PlacementMargin="-80,-50,0,0"
    ShouldConstrainToRootBounds="False">
</TeachingTip>
```



Canceling and deferring close

The Closing event can be used to cancel and/or defer the close of a teaching tip. This can be used to keep the teaching tip open or allow time for an action or custom animation to occur. When the closing of a teaching tip is canceled, IsOpen will go back to true, however, it will stay false during the deferral. A programmatic close can also be canceled.

> **Note**
>
> If no placement option would allow a teaching tip to fully show, teaching tip will iterate through its event lifecycle to force a close rather than display without an accessible close button. If the app cancels the Closing event, the teaching tip may remain open without an accessible Close button.

XAML

```
<TeachingTip x:Name="EnableNewSettingsTip"
    Title="New ways to protect your privacy!"
    Subtitle="Please close this tip and review our updated privacy policy
and privacy settings."
```

```
    Closing="OnTipClosing">
</TeachingTip>
```

C#

```
private void OnTipClosing(muxc.TeachingTip sender,
muxc.TeachingTipClosingEventArgs args)
{
    if (args.Reason == muxc.TeachingTipCloseReason.CloseButton)
    {
        using(args.GetDeferral())
        {
            bool success = UpdateUserSettings(User thisUsersID);
            if(!success)
            {
                // We were not able to update the settings!
                // Don't close the tip and display the reason why.
                args.Cancel = true;
                ShowLastErrorMessage();
            }
        }
    }
}
```

UWP and WinUI 2

> **ⓘ Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

The TeachingTip for UWP apps requires WinUI 2. For more info, including installation instructions, see WinUI. APIs for this control exist in the Microsoft.UI.Xaml.Controls namespace.

- ✓ **WinUI 2 Apis:** TeachingTip class
- ✓ Open the WinUI 2 Gallery app and see the TeachingTip in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

To use the code in this article with WinUI 2, use an alias in XAML (we use `muxc`) to represent the Windows UI Library APIs that are included in your project. See Get Started with WinUI 2 for more info.

XAML

```
xmlns:muxc="using:Microsoft.UI.Xaml.Controls"

<muxc:TeachingTip />

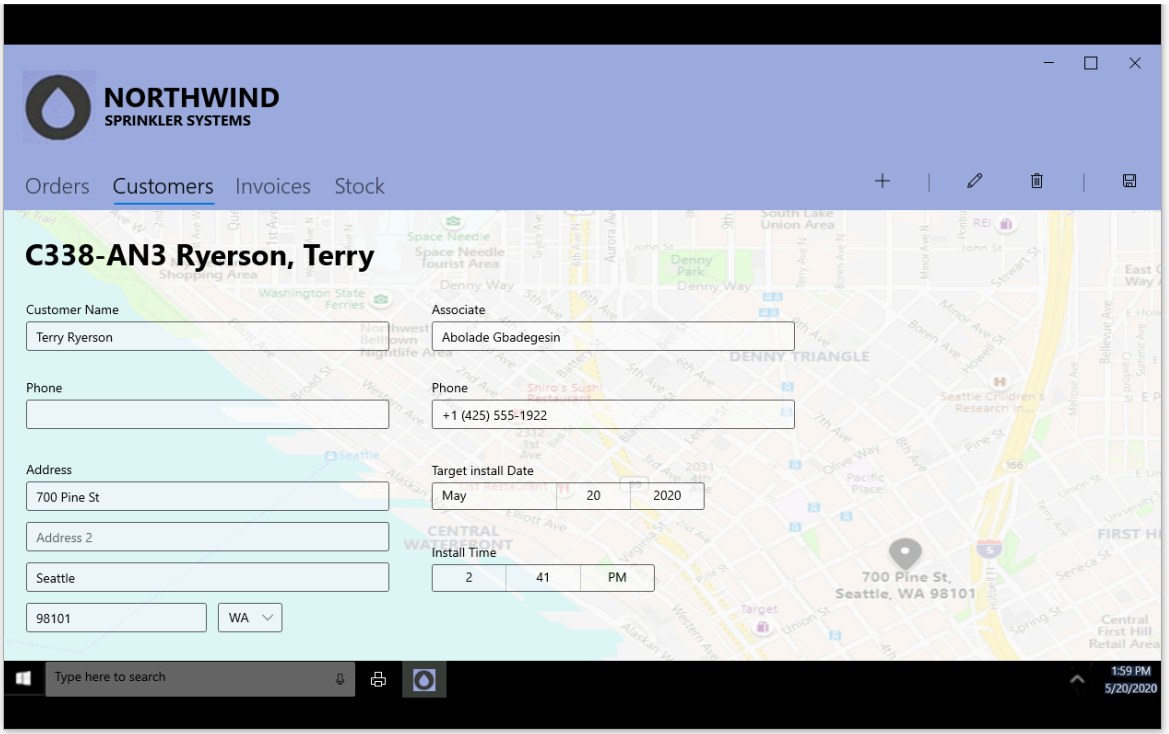
Forms

Article • 06/09/2022

A form is a group of controls that collect and submit data from users. Forms are typically used for settings pages, surveys, creating accounts, and much more.

This article discusses design guidelines for creating XAML layouts for forms.



When should you use a form?

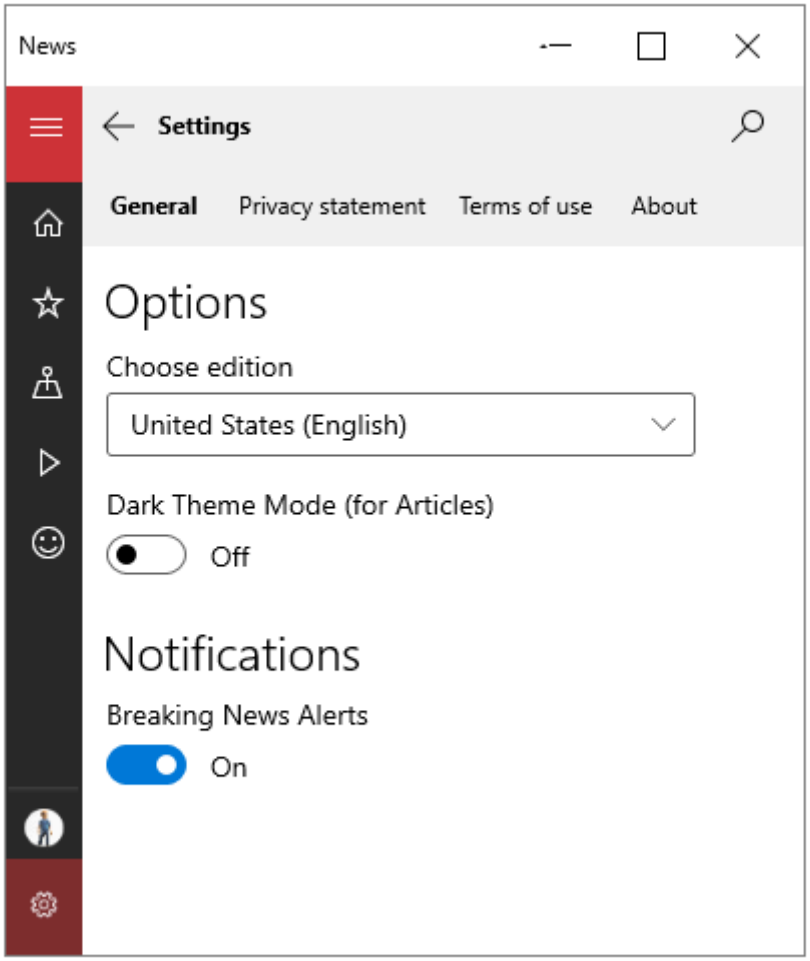
A form is a dedicated page for collecting data inputs that are clearly related to each other. You should use a form when you need to explicitly collect data from a user. You might create a form for a user to:

- Log into an account
- Sign up for an account
- Change app settings, such as privacy or display options
- Take a survey
- Purchase an item
- Give feedback

Types of forms

When thinking about how user input is submitted and displayed, there are two types of forms:

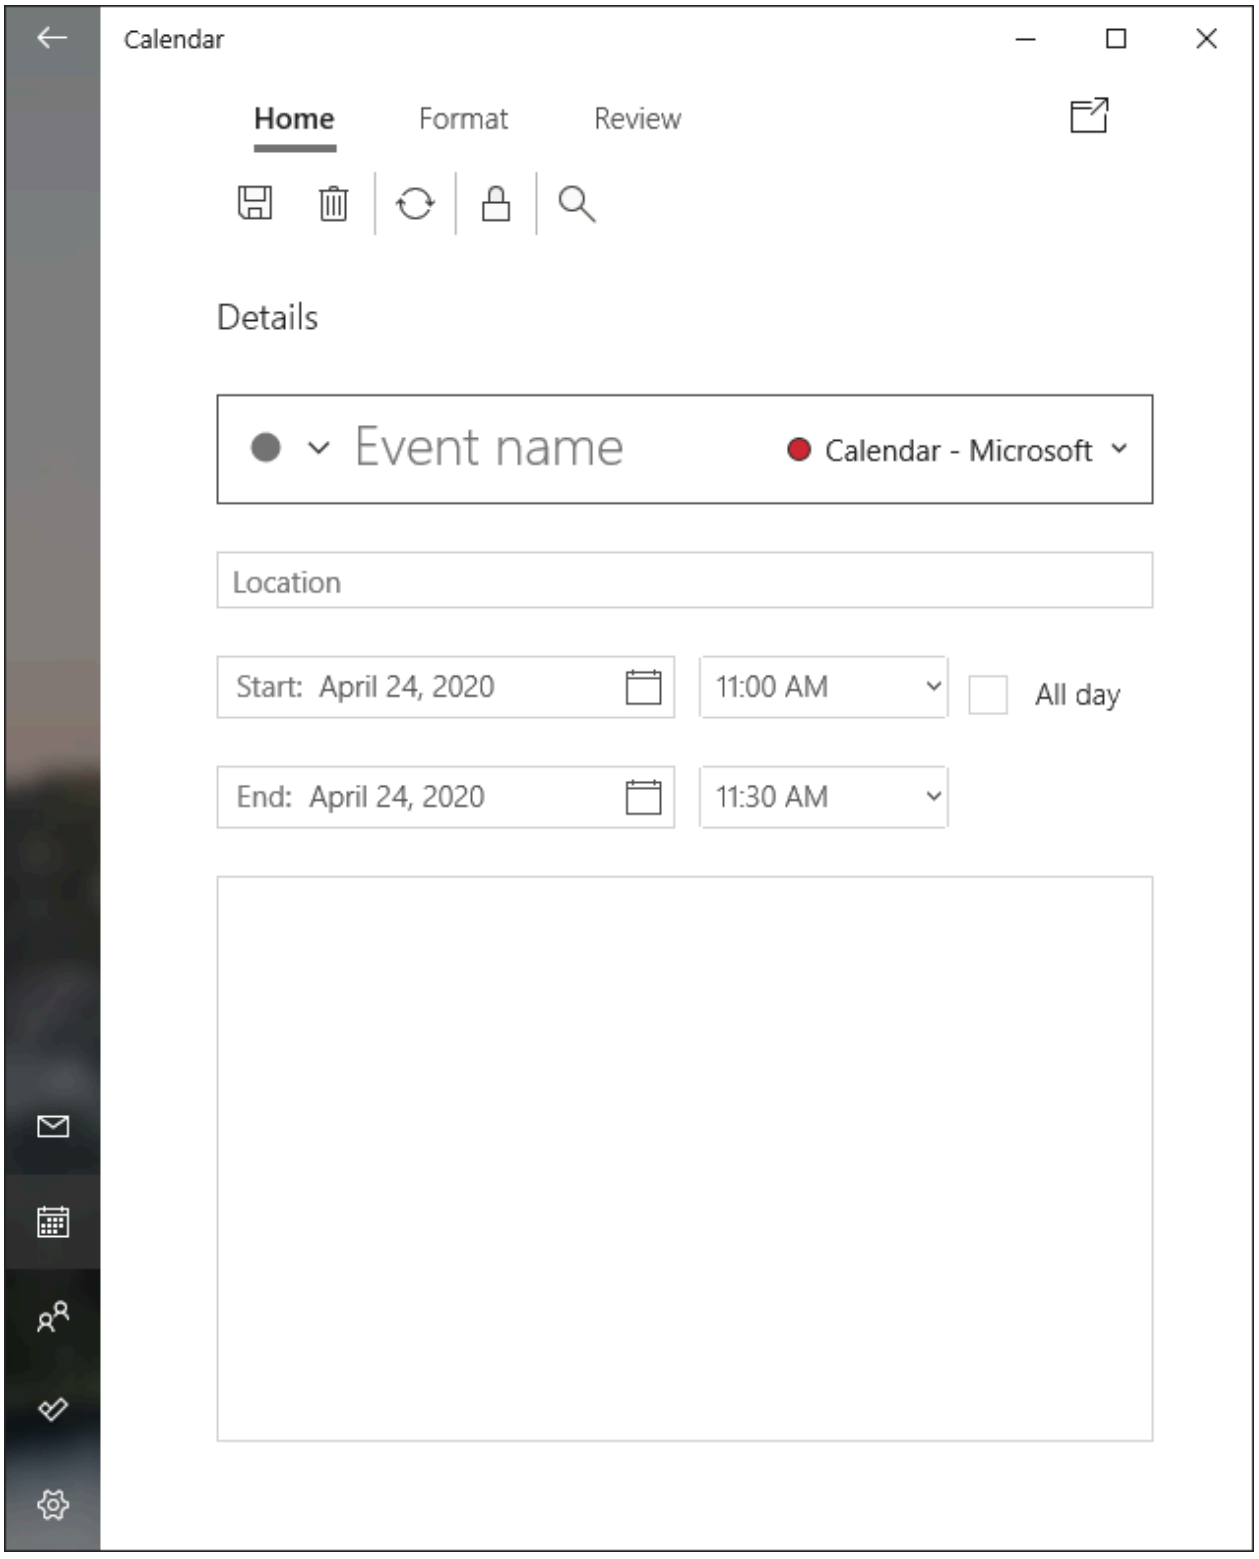
1. Instantly updating



Use an instantly updating form when you want users to immediately see the results of changing the values in the form. For example, in settings pages, the current selections are displayed, and any changes made to the selections are applied immediately. To acknowledge the changes in your app, you will need to add an event handler to each input control. If a user changes an input control, then your app can respond appropriately.

2. Submitting with button

The other type of form allows the user to choose when to submit data with a click of a button.



This type of form gives the user flexibility in responding. Typically, this type of form contains more free form input fields, and thus receives a greater variety of responses. To ensure valid user input and properly formatted data upon submission, consider the following recommendations:

- Make it impossible to submit invalid information by using the correct control (i.e., use a CalendarDatePicker rather than a TextBox for calendar dates). See more on selecting the appropriate input controls in your form in the Input Controls section later.

- When using TextBox controls, provide users a hint of the desired input format with the PlaceholderText property.
- Provide users with the appropriate on-screen keyboard by stating the expected input of a control with the InputScope property.
- Mark required input with an asterisk * on the label.
- Disable the submit button until all required information is filled in.
- If there is invalid data upon submission, mark the controls with invalid input with highlighted fields or borders, and require the user to resubmit the form.
- For other errors, such as failed network connection, make sure to display an appropriate error message to the user.

Layout

To facilitate the user experience and ensure that users are able to enter the correct input, consider the following recommendations for designing layouts for forms.

Labels

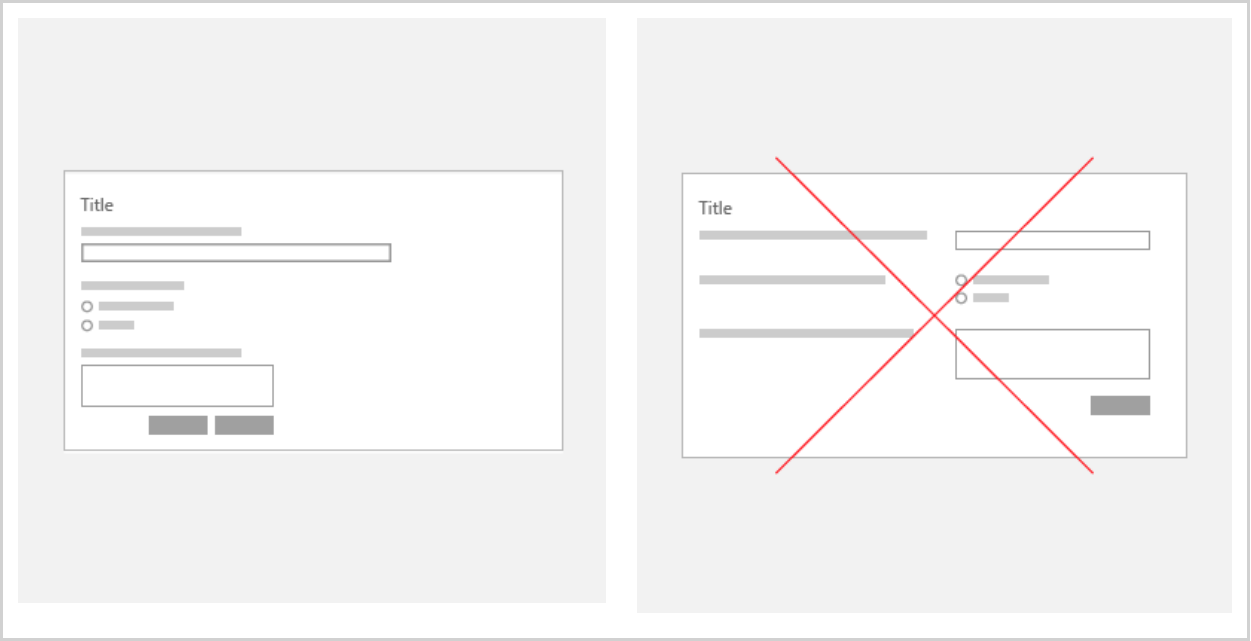
Labels should be left-aligned and placed above the input control. Many controls have a built-in Header property to display the label. For controls that don't have a Header property, or to label groups of controls, you can use a TextBlock instead.

To design for accessibility, label all individual and groups of controls for clarity for both human and screen readers.

For font styles, use the default Windows type ramp. Use `TitleTextBlockStyle` for page titles, `SubtitleTextBlockStyle` for group headings, and `BodyTextBlockStyle` for control labels.

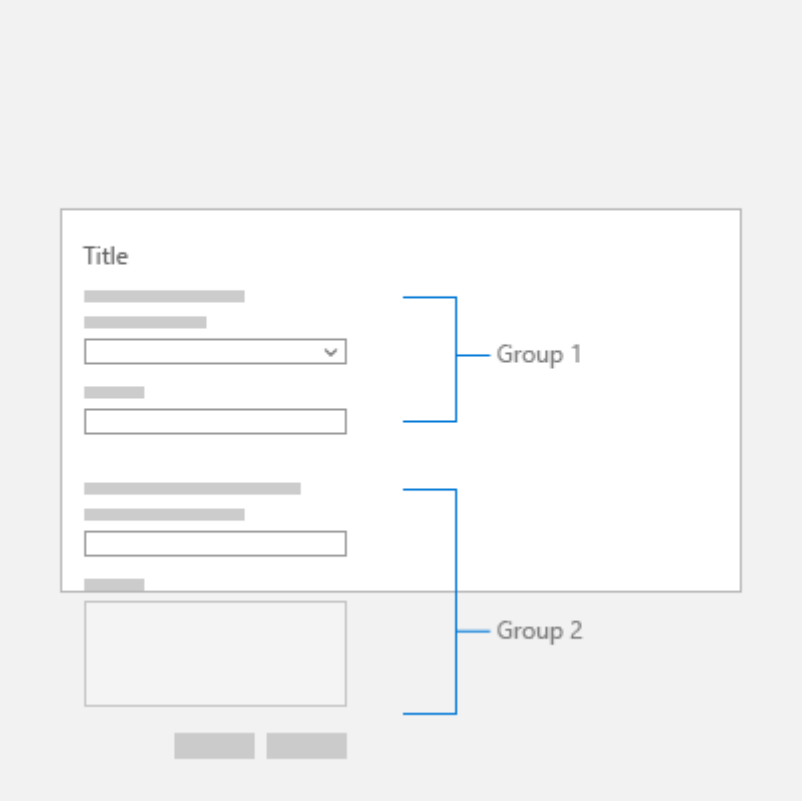
Expand table

Do	Don't



Spacing

To visually separate groups of controls from each other, use alignment, margins, and padding. Individual input controls are 80px in height and should be spaced 24px apart. Groups of input controls should be spaced 48px apart.



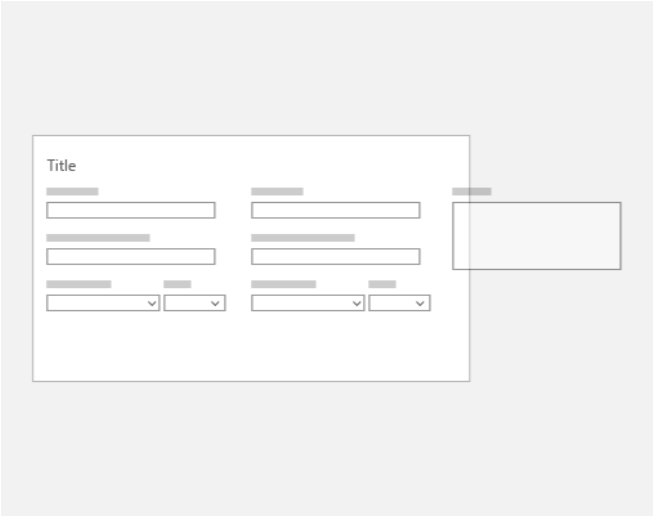
Columns

Creating columns can reduce unnecessary white space in forms, especially with larger screen sizes. However, if you would like to create a multi-column form, the number of

columns should depend on the number of input controls on the page and the screen size of the app window. Rather than overwhelm the screen with numerous input controls, consider creating multiple pages for your form.

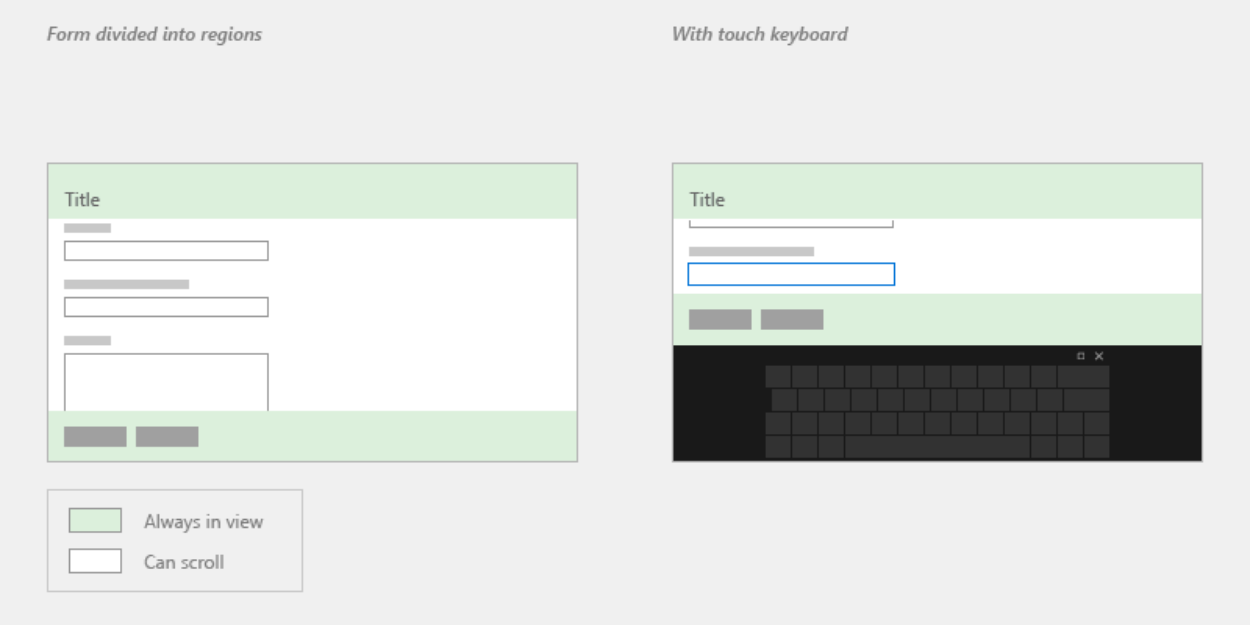
Expand table

Do	Don't
	



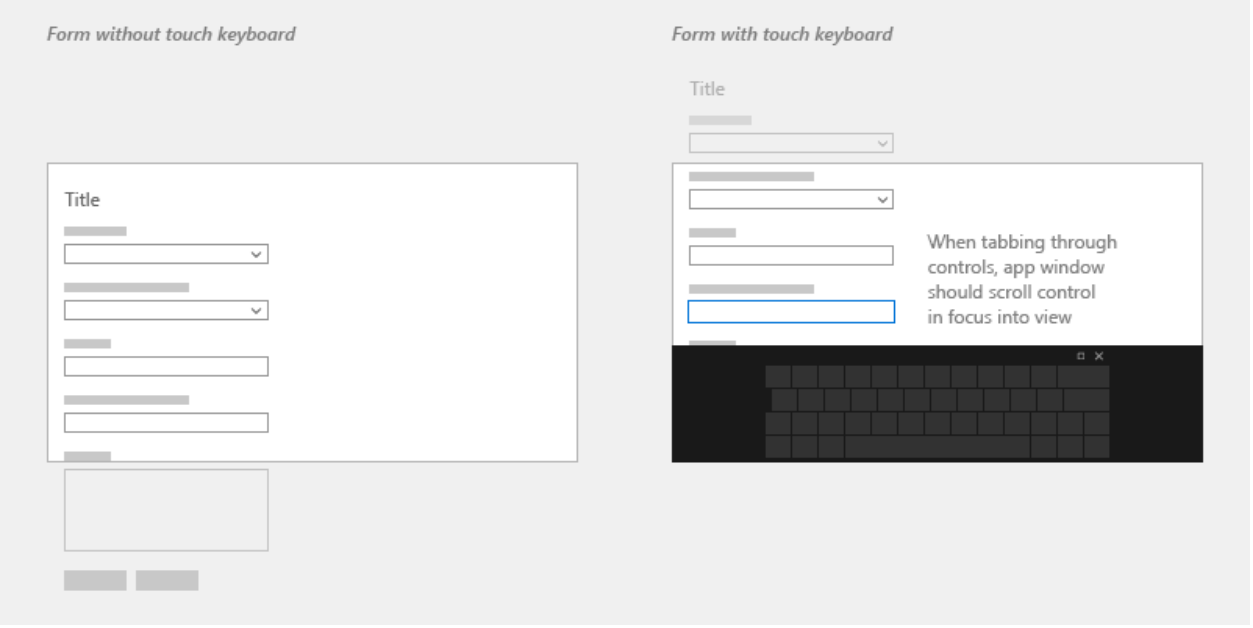
Responsive layout

Forms should resize as the screen or window size changes, so users don't overlook any input fields. For more information, see responsive design techniques. For example, you might want to keep specific regions of the form always in view, no matter the screen size.



Tab stops

Users can use the keyboard to navigate controls with tab stops. By default, the tab order of controls reflects the order in which they are created in XAML. To override the default behavior, change the **IsTabStop** or **TabIndex** properties of the control.



Input controls

Input controls are the UI elements that allow users to enter information into forms. Some common controls that can be added to forms are listed below, as well as information about when to use them.

Text input

Expand table

Control	Use	Example
TextBox	Capture one or multiple lines of text	Names, free form responses or feedback
PasswordBox	Collect private data by concealing the characters	Passwords, Social Security Numbers (SSN), PINs, credit card information
AutoSuggestBox	Show users a list of suggestions from a corresponding set of data as they type	Database search, mail to: line, previous queries
RichEditBox	Edit text files with formatted text, hyperlinks, and images	Upload file, preview, and edit in app

Selection

Expand table

Control	Use	Example
CheckBox	Select or deselect one or more action items	Agree to terms and conditions, add optional items, select all that apply
RadioButton	Select one option from two or more choices	Pick type, shipping method, etc.
ToggleSwitch	Choose one of two mutually exclusive options	On/off

> **Note**: If there are five or more selection items, use a list control.

Lists

Expand table

Control	Use	Example
ComboBox	Start in compact state and expand to show list of selectable items	Select from a long list of items, such as states or countries/regions
ListView	Categorize items and assign group headers, drag and drop items, curate content, and reorder items	Rank options
GridView	Arrange and browse image-based collections	Pick a photo, color, display theme

Numeric input

Expand table

Control	Use	Example
Slider	Select a number from a range of contiguous numerical values	Percentages, volume, playback speed
Rating	Rate with stars	Customer feedback

Date and Time

Expand table

Control	Use
CalendarView	Pick a single date or a range of dates from an always visible calendar
CalendarDatePicker	Pick a single date from a contextual calendar
DatePicker	Pick a single localized date when contextual info isn't important
TimePicker	Pick a single time value

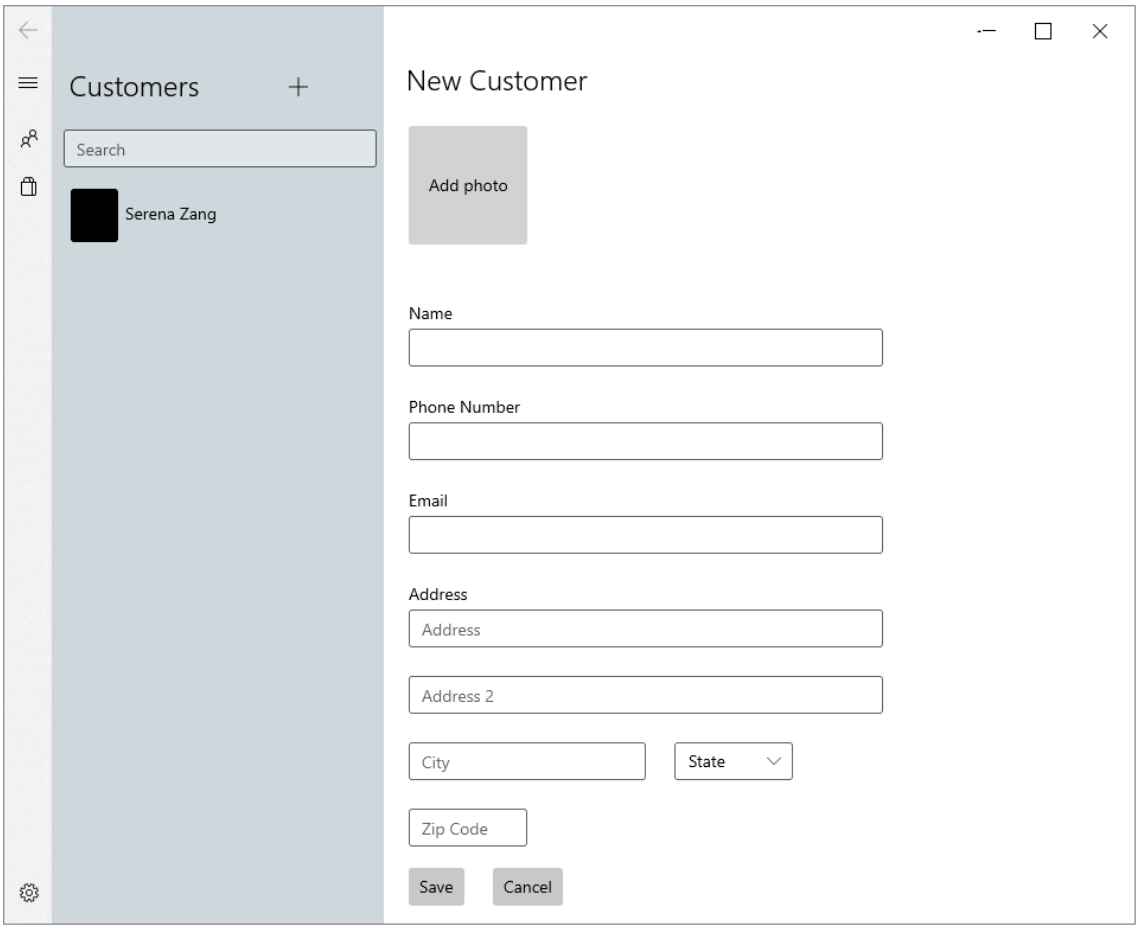
Additional Controls

For a complete list of UWP controls, see index of controls by function.

For more complex and custom UI controls, look at resources available from companies such as Telerik, SyncFusion, DevExpress, Infragistics, ComponentOne, and ActiPro.

One column form example

This example uses an Acrylic list/detail list view and NavigationView control.



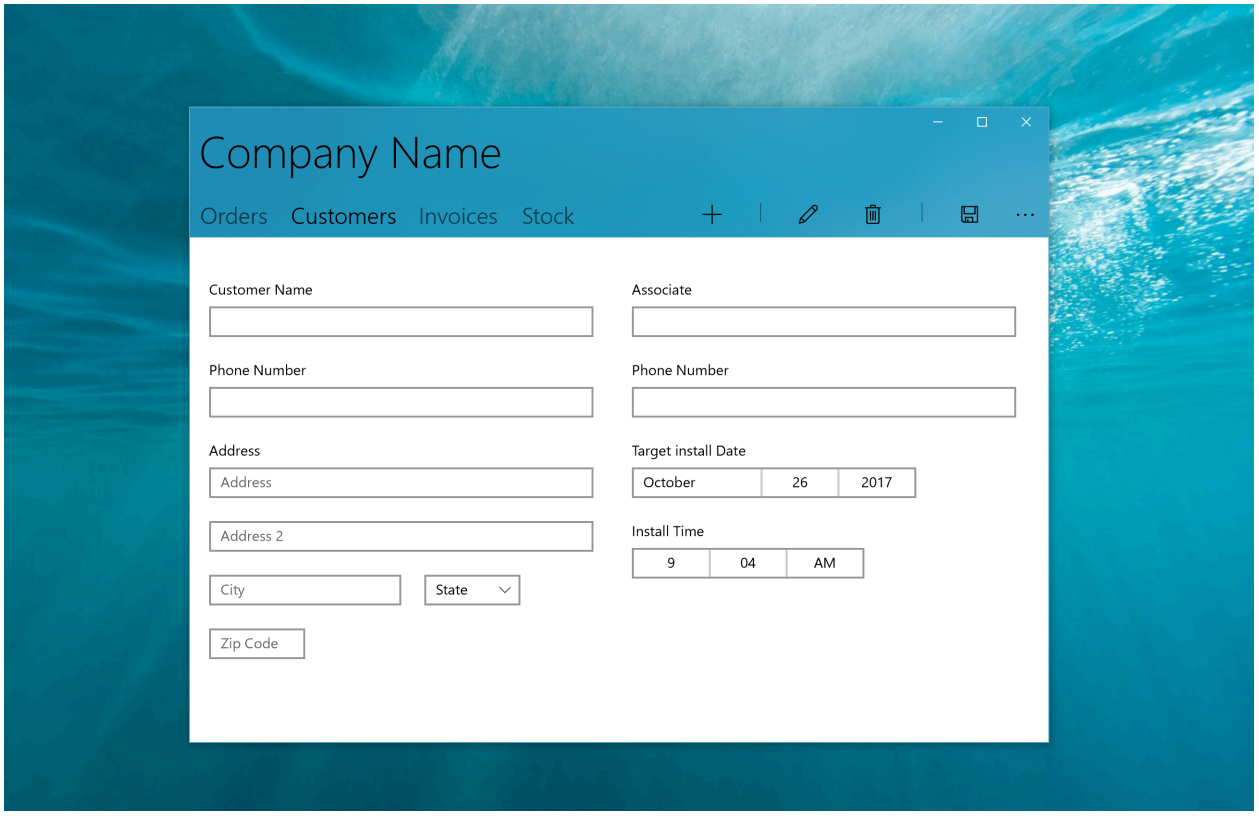
XAML

```
<StackPanel>
    <TextBlock Text="New Customer" Style="{StaticResource
TitleTextBlockStyle}"/>
    <Button Height="100" Width="100" Background="LightGray" Content="Add
photo" Margin="0,24" Click="AddPhotoButton_Click"/>
    <TextBox x:Name="Name" Header= "Name" Margin="0,24,0,0" MaxLength="32"
Width="400" HorizontalAlignment="Left" InputScope="PersonalFullName"/>
    <TextBox x:Name="PhoneNumber" Header="Phone Number" Margin="0,24,0,0"
MaxLength="15" Width="400" HorizontalAlignment="Left"
InputScope="TelephoneNumber" />
    <TextBox x:Name="Email" Header="Email" Margin="0,24,0,0" MaxLength="50"
Width="400" HorizontalAlignment="Left" InputScope="EmailNameOrAddress" />
    <TextBox x:Name="Address" Header="Address" PlaceholderText="Address"
Margin="0,24,0,0" MaxLength="50" Width="400" HorizontalAlignment="Left"
InputScope="EmailNameOrAddress" />
    <TextBox x:Name="Address2" Margin="0,24,0,0" PlaceholderText="Address 2"
MaxLength="50" Width="400" HorizontalAlignment="Left"
InputScope="EmailNameOrAddress" />
    <RelativePanel>
        <TextBox x:Name="City" PlaceholderText="City" Margin="0,24,0,0"
MaxLength="50" Width="200" HorizontalAlignment="Left"
InputScope="EmailNameOrAddress" />
```

```
        <ComboBox x:Name="State" PlaceholderText="State" Margin="24,24,0,0"
Width="100" RelativePanel.RightOf="City">
            <x:String>WA</x:String>
        </ComboBox>
    </RelativePanel>
    <TextBox x:Name="ZipCode" PlaceholderText="Zip Code" Margin="0,24,0,0"
MaxLength="6" Width="100" HorizontalAlignment="Left" InputScope="Number" />
    <StackPanel Orientation="Horizontal">
        <Button Content="Save" Margin="0,24" Click="SaveButton_Click"/>
        <Button Content="Cancel" Margin="24" Click="CancelButton_Click"/>
    </StackPanel>
</StackPanel>
```

Two column form example

This example uses the Pivot control, Acrylic background, and CommandBar in addition to input controls.



XAML

```
<Grid>
    <Pivot Background="{ThemeResource
SystemControlAccentAcrylicWindowAccentMediumHighBrush}" >
        <Pivot.TitleTemplate>
            <DataTemplate>
                <Grid>
                    <TextBlock Text="Company Name" Style="{ThemeResource
HeaderTextBlockStyle}"/>
                </Grid>
            </DataTemplate>
```

```
        </Pivot.TitleTemplate>
        <PivotItem Header="Orders" Margin="0"/>
        <PivotItem Header="Customers" Margin="0">
            <!--Form Example-->
            <Grid Background="White">
                <RelativePanel>
                    <StackPanel x:Name="Customer" Margin="20">
                        <TextBox x:Name="CustomerName" Header= "Customer
Name" Margin="0,24,0,0" MaxLength="320" Width="400"
HorizontalAlignment="Left" InputScope="PersonalFullName"/>
                        <TextBox x:Name="CustomerPhoneNumber" Header="Phone
Number" Margin="0,24,0,0" MaxLength="50" Width="400"
HorizontalAlignment="Left" InputScope="TelephoneNumber" />
                        <TextBox x:Name="Address" Header="Address"
PlaceholderText="Address" Margin="0,24,0,0" MaxLength="50" Width="400"
HorizontalAlignment="Left" InputScope="AlphanumericFullWidth" />
                        <TextBox x:Name="Address2" Margin="0,24,0,0"
PlaceholderText="Address 2" MaxLength="50" Width="400"
HorizontalAlignment="Left" InputScope="AlphanumericFullWidth" />
                        <RelativePanel>
                            <TextBox x:Name="City" PlaceholderText="City"
Margin="0,24,0,0" MaxLength="50" Width="200" HorizontalAlignment="Left"
InputScope="Text" />
                            <ComboBox x:Name="State" PlaceholderText="State"
Margin="24,24,0,0"  Width="100" RelativePanel.RightOf="City">
                                <x:String>WA</x:String>
                            </ComboBox>
                        </RelativePanel>
                        <TextBox x:Name="ZipCode" PlaceholderText="Zip Code"
Margin="0,24,0,0" MaxLength="6" Width="100" HorizontalAlignment="Left"
InputScope="Number" />
                    </StackPanel>
                    <StackPanel x:Name="Associate" Margin="20"
RelativePanel.RightOf="Customer">
                        <TextBox x:Name="AssociateName" Header= "Associate"
Margin="0,24,0,0" MaxLength="320" Width="400" HorizontalAlignment="Left"
InputScope="PersonalFullName"/>
                        <TextBox x:Name="AssociatePhoneNumber" Header="Phone
Number" Margin="0,24,0,0" MaxLength="50" Width="400"
HorizontalAlignment="Left" InputScope="TelephoneNumber" />
                        <DatePicker x:Name="TargetInstallDate"
Header="Target install Date" HorizontalAlignment="Left" Margin="0,24,0,0">
</DatePicker>
                        <TimePicker x:Name="InstallTime" Header="Install
Time" HorizontalAlignment="Left" Margin="0,24,0,0"></TimePicker>
                    </StackPanel>
                </RelativePanel>
            </Grid>
        </PivotItem>
        <PivotItem Header="Invoices"/>
        <PivotItem Header="Stock"/>
        <Pivot.RightHeader>
            <CommandBar OverflowButtonVisibility="Collapsed"
Background="Transparent">
                <AppBarButton Icon="Add"/>
```

```
                <AppBarSeparator/>
                <AppBarButton Icon="Edit" />
                <AppBarButton Icon="Delete"/>
                <AppBarSeparator/>
                <AppBarButton Icon="Save"/>
            </CommandBar>
        </Pivot.RightHeader>
    </Pivot>
</Grid>
```

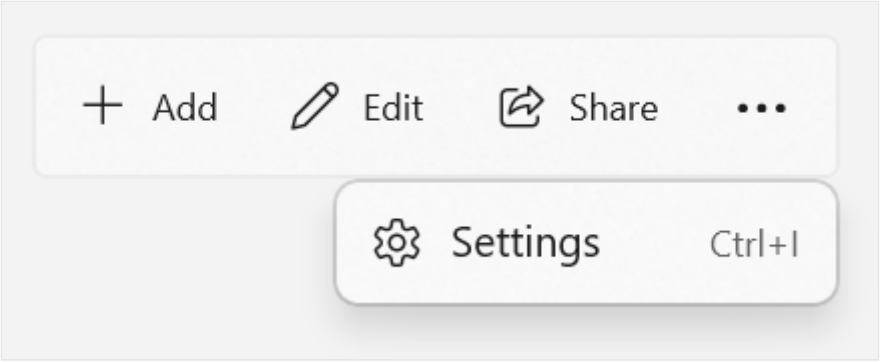
Icons in Windows apps

Article • 07/29/2024

Icons provide a visual shorthand for an action, concept, or product. By compressing meaning into a symbolic image, icons can cross language barriers and help conserve a valuable resource: screen space. Good icons harmonize with typography and with the rest of the design language. They don't mix metaphors, and they communicate only what's needed, as speedily and simply as possible.



Icons can appear within apps and outside them. Inside your app, you use icons to represent an action, such as copying text or going to the settings page.

This article describes icons within your app UI. To learn about icons that represent your app in Windows (app icons), see App icons.

Know when to use icons

Icons can save space, but when should you use them?

Use an icon for actions, like cut, copy, paste, and save, or for items on a navigation menu. Use an icon if it's easy for the user to understand what the icon means and it's simple enough to be clear at small sizes.

Don't use an icon if its meaning isn't clear, or if making it clear requires a complex shape.

Use the right type of icon

There are many ways to create an icon. You can use a symbol font like the Segoe Fluent Icons font. You can create your own vector-based image. You can even use a bitmap image, although we don't recommend it. Here's a summary of the ways that you can add an icon to your app.

To add an icon in your XAML app, you use either an IconElement or an IconSource.

This table shows the different kinds of icons that are derived from IconElement and IconSource.

Expand table

IconElement	IconSource	Description
AnimatedIcon	AnimatedIconSource	Represents an icon that displays and controls a visual that can animate in response to user interaction and visual state changes.
BitmapIcon	BitmapIconSource	Represents an icon that uses a bitmap as its content.
FontIcon	FontIconSource	Represents an icon that uses a glyph from the specified font.
IconSourceElement	N/A	Represents an icon that uses an IconSource as its content.
ImageIcon	ImageIconSource	Represents an icon that uses an image as its content.
PathIcon	PathIconSource	Represents an icon that uses a vector path as its content.
SymbolIcon	SymbolIconSource	Represents an icon that uses a glyph from the `SymbolThemeFontFamily` resource as its content.

IconElement vs. IconSource

IconElement is a FrameworkElement, so it can be added to the XAML object tree just like any other element of your app's UI. However, it can't be added to a ResourceDictionary and reused as a shared resource.

IconSource is similar to IconElement; however, because it is not a FrameworkElement, it can't be used as a standalone element in your UI, but it can be shared as a resource. IconSourceElement is a special icon element that wraps an IconSource so you can use it anywhere you need an IconElement. An example of these features is shown in the next section.

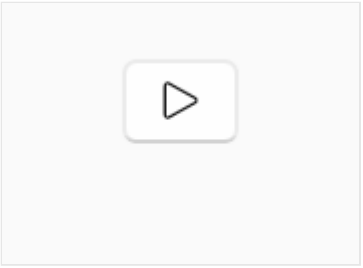
IconElement examples

You can use an IconElement-derived class as a standalone UI component.

This example shows how to set an icon glyph as the content of a Button. Set the button's FontFamily to `SymbolThemeFontFamily` and its content property to the Unicode value of the glyph that you want to use.

XAML

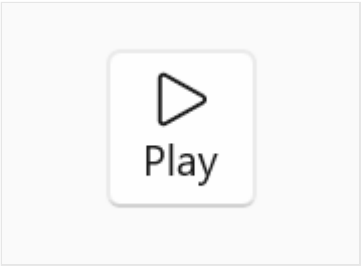
```
<Button FontFamily="{ThemeResource SymbolThemeFontFamily}"
        Content="&#xE768;"/>
```



You can also explicitly add one of the icon element objects listed previously, like SymbolIcon. This gives you more types of icons to choose from. It also lets you combine icons and other types of content, such as text, if you want.

XAML

```
<Button>
    <StackPanel>
        <SymbolIcon Symbol="Play"/>
        <TextBlock Text="Play" HorizontalAlignment="Center"/>
    </StackPanel>
</Button>
```



This example shows how you can define a FontIconSource in a ResourceDictionary, and then use an IconSourceElement to reuse the resource in different places of your app.

XAML

```
<!--App.xaml-->
<Application
   ...>
    <Application.Resources>
        <ResourceDictionary>
            ...
```

```
            <!-- Other app resources here -->

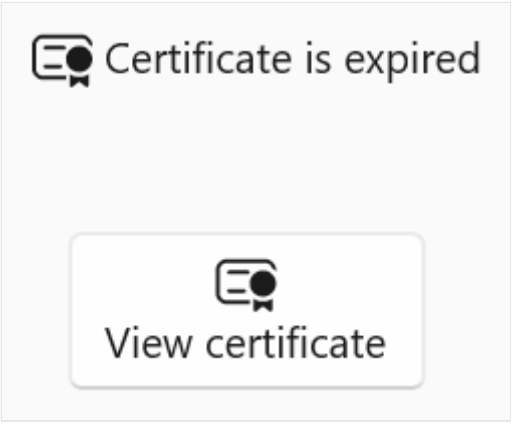
            <FontIconSource x:Key="CertIconSource" Glyph="&#xEB95;"/>

        </ResourceDictionary>
    </Application.Resources>
</Application>
```

XAML

```
<StackPanel Orientation="Horizontal">
    <IconSourceElement IconSource="{StaticResource CertIconSource}"/>
    <TextBlock Text="Certificate is expired" Margin="4,0,0,0"/>
</StackPanel>

<Button>
    <StackPanel>
        <IconSourceElement IconSource="{StaticResource CertIconSource}"/>
        <TextBlock Text="View certificate" HorizontalAlignment="Center"/>
    </StackPanel>
</Button>
```



Open the WinUI 3 Gallery app to see IconElement in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

Icon properties

You often place icons in your UI by assigning one to an *icon* property of another XAML element. *Icon* properties that include *Source* in the name take an IconSource; otherwise, the property takes an IconElement.

This list shows some common elements that have an *icon* property.

Expand table

Commands/Actions	Navigation	Status/Other
AppBarButton.Icon	NavigationViewItem.Icon	AnimatedIcon.FallbackIconSource
AppBarToggleButton.Icon	SelectorBarItem.Icon	AnimatedIconSource.FallbackIconSource
AutoSuggestBox.QueryIcon	TabViewItem.IconSource	IconSourceElement.IconSource
MenuFlyoutItem.Icon		InfoBadge.IconSource
MenuFlyoutSubItem.Icon		InfoBar.IconSource
SwipeItem.IconSource		TeachingTip.IconSource
XamlUICommand.IconSource		

> **Tip**
>
> You can view these controls in the WinUI 3 Gallery app to see examples of how icons are used with them.

The remaining examples on this page show how to assign an icon to the `icon` property of a control.

FontIcon and SymbolIcon

The most common way to add icons to your app is to use the system icons provided by the icon fonts in Windows. Windows 11 introduces a new system icon font, Segoe Fluent Icons, which provides more than 1,000 icons designed for the Fluent Design language. It might not be intuitive to get an icon from a font, but Windows font display technology means these icons will look crisp and sharp on any display, at any resolution, and at any size.

> **Important**
>
> **Default font family**
>
> Rather than specifying a **FontFamily** directly, FontIcon and SymbolIcon use the font family defined by the `SymbolThemeFontFamily` XAML theme resource. By default, this resource uses the Segoe Fluent Icon font family. If your app is run on Windows 10, version 20H2 or earlier, the Segoe Fluent Icon font family is not available and the `SymbolThemeFontFamily` resource falls back to the **Segoe MDL2 Assets** font family instead.

Symbol enumeration

Many common glyphs from the `SymbolThemeFontFamily` are included in the Symbol enumeration. If the glyph you need is available as a Symbol, you can use a SymbolIcon anywhere you would use a FontIcon with the default font family.

You also use Symbol names to set an *`icon`* property in XAML using attribute syntax, like this

XAML

```
<AppBarButton Icon="Send" Label="Send"/>
```

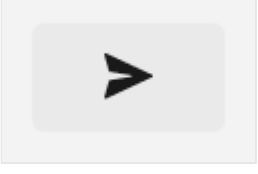
> **Tip**
>
> You can only use Symbol names to set an *`icon`* property using the shortened **attribute syntax**. All other icon types must be set using the longer **property element syntax**, as shown in other examples on this page.

Font icons

Only a small subset of Segoe Fluent Icon glyphs are available in the Symbol enumeration. To use any of the other available glyphs, use a FontIcon. This example shows how to create an AppBarButton with the `SendFill` icon.

XAML

```
<AppBarButton Label="Send">
    <AppBarButton.Icon>
        <FontIcon Glyph="&#xE725;"/>
    </AppBarButton.Icon>
</AppBarButton>
```

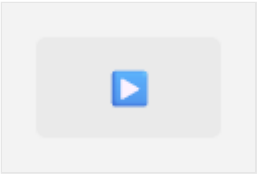


If you don't specify a FontFamily, or you specify a FontFamily that is not available on the system at runtime, the FontIcon falls back to the default font family defined by the `SymbolThemeFontFamily` theme resource.

You can also specify an icon using a Glyph value from any available font. This example shows how to use a Glyph from the Segoe UI Emoji font.

XAML

```
<AppBarToggleButton Label="FontIcon">
    <AppBarToggleButton.Icon>
        <FontIcon FontFamily="Segoe UI Emoji" Glyph="&#x25B6;"/>
    </AppBarToggleButton.Icon>
</AppBarToggleButton>
```



For more information and examples, see the FontIcon and SymbolIcon class documentation.

> **Tip**
>
> Use the Iconography page in the WinUI 3 Gallery app to view, search, and copy code for all the icons available in Segoe Fluent Icons.

Open the WinUI 3 Gallery app to the Iconography page

AnimatedIcon

Motion is an important part of the Fluent Design language. Animated icons draw attention to specific entry points, provide feedback from state to state, and add delight to an interaction.

You can use animated icons to implement lightweight, vector-based icons with motion using Lottie animations.

For more information and examples, see Animated icons and the AnimatedIcon class documentation.

Open the WinUI 3 Gallery app to see AnimatedIcon in action

PathIcon

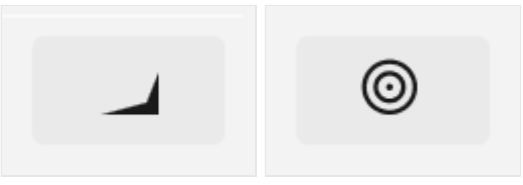
You can use a PathIcon to create custom icons that use vector-based shapes, so they always look sharp. However, creating a shape using a XAML Geometry is complicated because you have to individually specify each point and curve.

This example shows two different ways to define the Geometry used in a PathIcon.

XAML

```
<AppBarButton Label="PathIcon">
    <AppBarButton.Icon>
        <PathIcon Data="F1 M 16,12 20,2L 20,16 1,16"/>
    </AppBarButton.Icon>
</AppBarButton>

<AppBarButton Label="Circles">
    <AppBarButton.Icon>
        <PathIcon>
            <PathIcon.Data>
                <GeometryGroup>
                    <EllipseGeometry RadiusX="15" RadiusY="15"
Center="90,90" />
                    <EllipseGeometry RadiusX="50" RadiusY="50"
Center="90,90" />
                    <EllipseGeometry RadiusX="70" RadiusY="70"
Center="90,90" />
                    <EllipseGeometry RadiusX="100" RadiusY="100"
Center="90,90" />
                    <EllipseGeometry RadiusX="120" RadiusY="120"
Center="90,90" />
                </GeometryGroup>
            </PathIcon.Data>
        </PathIcon>
    </AppBarButton.Icon>
</AppBarButton>
```



To learn more about using Geometry classes to create custom shapes, see the class documentation and Move and draw commands for geometries. Also see the WPF Geometry documentation. The WinUI Geometry class doesn't have all the same features as the WPF class, but creating shapes is the same for both.

For more information and examples, see the PathIcon class documentation.

BitmapIcon and ImageIcon

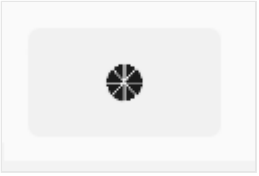
You can use a BitmapIcon or ImageIcon to create an icon from an image file (such as PNG, GIF, or JPEG), although we don't recommend it if another option is available. Bitmap images are created at a specific size, so they have to be scaled up or down depending on how large you want the icon to be and the resolution of the screen. When the image is scaled down (shrunk), it can appear blurry. When it's scaled up, it can appear blocky and pixelated.

BitmapIcon

By default, a BitmapIcon strips out all color information from the image and renders all non-transparent pixels in the Foreground color. To create a monochrome icon, use a solid image on a transparent background in PNG format. Other image formats will load apparently without error but result in a solid block of the Foreground color.

XAML

```
<AppBarButton Label="ImageIcon">
    <AppBarButton.Icon>
        <ImageIcon Source="ms-appx:///Assets/slices3.png"/>
    </AppBarButton.Icon>
</AppBarButton>
```



You can override the default behavior by setting the ShowAsMonochrome property to `false`. In this case, the BitmapIcon behaves the same as an ImageIcon for supported bitmap file types (SVG files are not supported).

XAML

```
<BitmapIcon UriSource="ms-appx:///Assets/slices3.jpg"
            ShowAsMonochrome="False"/>
```

For more information and examples, see the BitmapIcon class documentation.

Tip

Usage of BitmapIcon is similar to usage of BitmapImage; see the **BitmapImage** class for more information that's applicable to BitmapIcon, like setting the UriSource property in code.

ImageIcon

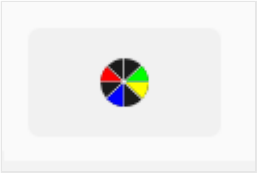
An ImageIcon shows the image provided by one of the ImageSource-derived classes. The most common is BitmapSource, but as mentioned previously, we don't recommend bitmap images for icons due to potential scaling issues.

Scalable Vector Graphics (SVG) resources are ideal for icons, because they always look sharp at any size or resolution. You can use an SVGImageSource with an ImageIcon, which supports secure static mode from the SVG specification but does not support animations or interactions. For more information, see SVGImageSource and SVG support.

An ImageIcon ignores the Foreground property, so it always shows the image in its original color. Because Foreground color is ignored, the icon doesn't respond to visual state changes when used in a button or other similar control.

XAML

```
<AppBarButton Label="ImageIcon">
    <AppBarButton.Icon>
        <ImageIcon Source="ms-appx:///Assets/slices3.svg"/>
    </AppBarButton.Icon>
</AppBarButton>
```



For more information and examples, see the ImageIcon class documentation.

Tip

Usage of ImageIcon is similar to the Image control; see the **Image** class for more information that's applicable to ImageIcon. One notable difference is that with ImageIcon, only the first frame of a multi-frame image (like an animated GIF) is used. To use animated icons, see **AnimatedIcon**.

AnimatedIcon

Article • 07/29/2024

An AnimatedIcon control plays animated images in response to user interaction and visual state changes.

Animated icons can draw attention to a UI component, such as the next button in a tutorial, or simply reflect the action associated with the icon in an entertaining and interesting way.

Custom animations can be created with Adobe AfterEffects and rendered with the Lottie-Windows library to use as an animated icon in your WinUI application. For more detail, see Use Lottie to create animated content for an AnimatedIcon later in this article.

The following example shows a basic animated search icon that was created in Adobe AfterEffects and rendered through Lottie.

Is this the right control?

Use the AnimatedIcon control when a control's icon needs to animate in response to user interaction with the control, such as when a user hovers over a button or clicks it.

Do not use an AnimatedIcon if the animation is not triggered by a visual state transition, and plays in a loop, plays one time only, or can be paused. Use AnimatedVisualPlayer instead.

Do not use AnimatedIcon for anything other than an icon, or where the control does not support an IconElement or IconElementSource property. Use AnimatedVisualPlayer instead.

When an animated icon is not required, use FontIcon, SymbolIcon, or BitmapIcon instead.

Differences between AnimatedIcon and AnimatedVisualPlayer

AnimatedIcon is an IconElement, which can be used anywhere an element or IconElement is required (such as NavigationViewItem.Icon), and is controlled through a

State property.

AnimatedVisualPlayer is a more general animation player, that is controlled through methods such as Play and Pause, and can be used anywhere in an application.

Use Lottie to create animated content for an AnimatedIcon

Defining an animation for an AnimatedIcon begins the same as the process to define an animation for an AnimatedVisualPlayer. You must create, or obtain, the Lottie file for the icon you want to add and run that file through LottieGen. LottieGen generates code for a C++/WinRT class that you can then instantiate and use with an AnimatedIcon.

> **Note**
>
> The AutoSuggestBox control uses the AnimatedVisuals.AnimatedFindVisualSource class, which was generated using the LottieGen tool.

You can also define markers in the animation definition to indicate playback time positions. You can then set the AnimatedIcon state to these markers. For example, if you have a playback position in the Lottie file marked "PointerOver", you can set the AnimatedIcon state to "PointerOver" and move the animation to that playback position.

Defining a color property in your Lottie animation named "Foreground" lets you to set the color using the AnimatedIcon.Foreground property.

Recommendations

- Please view the UX guidance for Icons for Windows Apps to ensure your icons match the design principles.
- Limit the number of animated icons on a single screen or view. Only animate icons to draw the user's attention to where they need to take action or when they are performing an action.

Create an animated icon

✓ **Important APIs:** AnimatedIcon class

Open the WinUI 3 Gallery app to see AnimatedIcon in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

Add an AnimatedIcon to a Button

The following example demonstrates a back button that displays an animated back icon on a PointerEntered event.

- The `AnimatedBackVisualSource` is a class created with the LottieGen command line tool.
- The FallbackIconSource is used when animations can't be played, such as on older versions of Windows that don't support Lottie animations.
- If the user turns animations off in their system settings, AnimatedIcon displays the final frame of the state transition the controls was in.

XAML

```
<Button PointerEntered="Button_PointerEntered"
PointerExited="Button_PointerExited">
    <AnimatedIcon x:Name='BackAnimatedIcon'>
        <AnimatedIcon.Source>
            <animatedvisuals:AnimatedBackVisualSource/>
        </AnimatedIcon.Source>
        <AnimatedIcon.FallbackIconSource>
            <SymbolIconSource Symbol='Back'/>
        </AnimatedIcon.FallbackIconSource>
    </AnimatedIcon>
</Button>
```

cs

```
private void Button_PointerEntered(object sender, PointerRoutedEventArgs e)
{
    AnimatedIcon.SetState(this.BackAnimatedIcon, "PointerOver");
}

private void Button_PointerExited(object sender, PointerRoutedEventArgs e)
{
    AnimatedIcon.SetState(this.BackAnimatedIcon, "Normal");
}
```

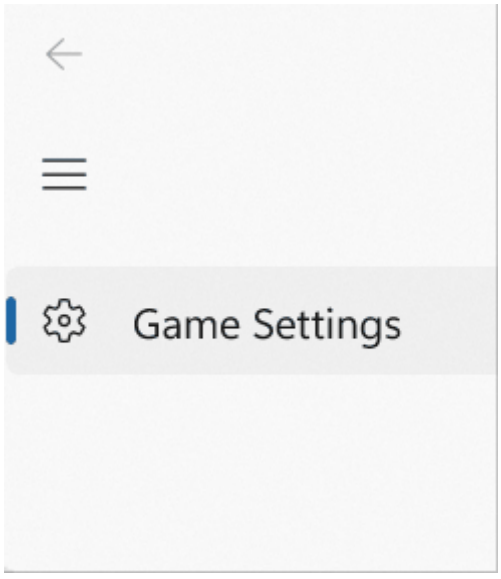
Add an AnimatedIcon to NavigationViewItem

The NavigationViewItem control automatically sets common states on an AnimatedIcon based on the state of the control, if those markers are defined in the Lottie animation.

For example, the following example shows how to set a custom animation (`GameSettingsIcon`) that was generated by the LottieGen tool:

XAML

```
<NavigationView.MenuItems>
    <NavigationViewItem Content = "Game Settings">
        <NavigationViewItem.Icon>
            <AnimatedIcon x:Name='GameSettingsIcon'>
                <AnimatedIcon.Source>
                    <animatedvisuals:AnimatedSettingsVisualSource/>
                </AnimatedIcon.Source>
                <AnimatedIcon.FallbackIconSource>
                    <FontIconSource FontFamily="Segoe MDL2 Assets"
Glyph="&#xE713;"/>
                </AnimatedIcon.FallbackIconSource>
            </AnimatedIcon>
        </NavigationViewItem.Icon>
    </NavigationViewItem>
</NavigationView.MenuItems>
```



The NavigationViewItem automatically sets the following states on the AnimatedIcon:

- Normal
- PointerOver
- Pressed
- Selected
- PressedSelected
- PointerOverSelected

If `GameSettingsIcon` has a marker defined for "NormalToPointerOver", the icon will be animated until the pointer moves over the NavigationViewItem. See the following section for more information on creating markers.

Define AnimatedIcon markers

To create the custom `GameSettingsIcon` in the previous example, run a Lottie JSON file (with markers) through the Windows LottieGen tool to generate the animation code as a C# class.

Once you run your Lottie file through LottieGen you can add the CodeGen output class to your project. See the LottieGen tutorial for more information.

Setting the AnimatedIcon state to a new value also sets a playback position in the Lottie animation for the transition from the old state to the new state. These playback positions are also identified with markers in the Lottie file. Specific markers for the start of the transition or the end of the transition can also be defined.

For example, the AutoSuggestBox control uses an AnimatedIcon that animates with the following states:

- Normal
- PointerOver
- Pressed

You can define markers in your Lottie file with those state names. You can also define markers as follows:

- Insert "To" between state names. For example, if you define a "NormalToPointerOver" marker, changing the AnimatedIcon state from "Normal" to "PointerOver" will cause it to move to this marker's playback position.
- Append "_Start" or "_End" to a marker name. For example defining markers "NormalToPointerOver_Start" and "NormalToPointerOver_End" and changing the AnimatedIcon state from "Normal" to "PointerOver" will cause it to jump to the _Start marker's playback position and then animate to the _End playback position.

The exact algorithm used to map AnimatedIcon State changes to marker playback positions:

- Check the provided file's markers for the markers "[PreviousState]To[NewState]_Start" and "[PreviousState]To[NewState]_End". If both are found play the animation from "[PreviousState]To[NewState]_Start" to "[PreviousState]To[NewState]_End".

- If "[PreviousState]To[NewState]_Start" is not found but "[PreviousState]To[NewState]_End" is found, then hard cut to the "[PreviousState]To[NewState]_End" playback position.
- If "[PreviousState]To[NewState]_End" is not found but "[PreviousState]To[NewState]_Start" is found, then hard cut to the "[PreviousState]To[NewState]_Start" playback position.
- Check if the provided IAnimatedVisualSource2's markers for the marker "[PreviousState]To[NewState]". If it is found then hard cut to the "[PreviousState]To[NewState]" playback position.
- Check if the provided IAnimatedVisualSource2's markers for the marker "[NewState]". If it is found, then hard cut to the "[NewState]" playback position.
- Check if the provided IAnimatedVisualSource2's markers has any marker which ends with "To[NewState]_End". If any marker is found which has that ending, hard cut to the first marker found with the appropriate ending's playback position.
- Check if "[NewState]" parses to a float. If it does, animated from the current position to the parsed float.
- Hard cut to playback position 0.0.

The following example shows the marker format in a Lottie JSON file. See the AnimatedIcon guidance for more detail.

JSON

```
"markers":[{"tm":0,"cm":"NormalToPointerOver_Start","dr":0},
{"tm":9,"cm":"NormalToPointerOver_End","dr":0},

{"tm":10,"cm":"NormalToPressed_Start","dr":0},
{"tm":19,"cm":"NormalToPressed_End","dr":0},

{"tm":20,"cm":"PointerOverToNormal_Start","dr":0},
{"tm":29,"cm":"PointerOverToNormal_End","dr":0},

{"tm":30,"cm":"PointerOverToPressed_Start","dr":0},
{"tm":39,"cm":"PointerOverToPressed_End","dr":0},

{"tm":40,"cm":"PressedToNormal_Start","dr":0},
{"tm":49,"cm":"PressedToNormal_End","dr":0},

{"tm":50,"cm":"PressedToPointerOver_Start","dr":0},
{"tm":69,"cm":"PressedToPointerOver_End","dr":0},

{"tm":90,"cm":"PressedToNormal_Start","dr":0},
{"tm":99,"cm":"PressedToNormal_End","dr":0},

{"tm":100,"cm":"PressedToPointerOver_Start","dr":0},
{"tm":101,"cm":"PressedToPointerOver_End","dr":0}]
```

Adding a Standalone AnimatedIcon

The following example is a button that the user clicks to Accept a prompt.

The `MyAcceptAnimation` class is created with the LottieGen tool.

The FallbackIconSource will be used rather than the animation when animations can't be played, such as on older versions of Windows that don't support Lottie animations.

If the end user turns off animations in their system settings, AnimatedIcon will display the final frame of the state transition the controls was in.

XML

```
<Button PointerEntered="HandlePointerEntered"
PointerExited="HandlePointerExited">
    <AnimatedIcon x:Name='AnimatedIcon1'>
        <local:MyAcceptAnimation/>
        <AnimatedIcon.FallbackIconSource>
            <SymbolIconSource Symbol='Accept'/>
        </AnimatedIcon.FallbackIconSource>
    </AnimatedIcon>
</Button>
```

cs

```
private void Button_PointerEntered(object sender, PointerRoutedEventArgs e)
{
    AnimatedIcon.SetState(this.AnimatedIcon1, "PointerOver");
}

private void Button_PointerExited(object sender, PointerRoutedEventArgs e)
{
    AnimatedIcon.SetState(this.StackPaAnimatedIcon1nel1, "Normal");
}
```

UWP and WinUI 2

> **ⓘ Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.

This section contains information you need to use the control in a UWP or WinUI 2 app.

The AnimatedIcon for UWP apps requires WinUI 2. For more info, including installation instructions, see WinUI 2. APIs for this control exist in the Microsoft.UI.Xaml.Controls namespace.

- ✓ **WinUI 2 Apis:** AnimatedIcon class
- ✓ Open the WinUI 2 Gallery app and see the AnimatedIcon in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

To use the code in this article with WinUI 2, use an alias in XAML (we use `muxc`) to represent the Windows UI Library APIs that are included in your project. See Get Started with WinUI 2 for more info.

XAML

```
xmlns:muxc="using:Microsoft.UI.Xaml.Controls"

<muxc:AnimatedIcon />
```

Images and image brushes

Article • 02/26/2025

To display an image, you can use either the **Image** object or the **ImageBrush** object. An Image object renders an image, and an ImageBrush object paints another object with an image.

Are these the right elements?

Use an **Image** element to display a stand-alone image in your app.

Use an **ImageBrush** to apply an image to another object. Uses for an ImageBrush include decorative effects for text, or backgrounds for controls or layout containers.

Create an image

✓ **Important APIs:** Image class, Source property, ImageBrush class, ImageSource property

Open the WinUI 3 Gallery app and see ImageBrushes in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

Image

This example shows how to create an image by using the Image object.

XAML

```
<Image Width="200" Source="sunset.jpg" />
```

Here's the rendered Image object.

In this example, the Source property specifies the location of the image that you want to display. You can set the Source by specifying an absolute URL (for example, `http://contoso.com/myPicture.jpg`) or by specifying a URL that is relative to your app packaging structure. For our example, we put the "sunset.jpg" image file in the root folder of our project and declare project settings that include the image file as content.

ImageBrush

With the ImageBrush object, you can use an image to paint an area that takes a Brush object. For example, you can use an ImageBrush for the value of the Fill property of an Ellipse or the Background property of a Canvas.

The next example shows how to use an ImageBrush to paint an Ellipse.

XAML

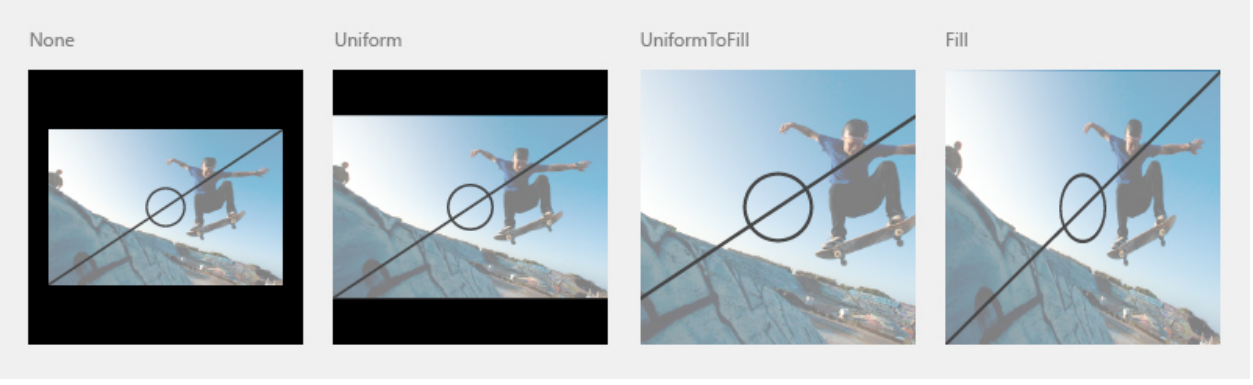
```
<Ellipse Height="200" Width="300">
   <Ellipse.Fill>
     <ImageBrush ImageSource="sunset.jpg" />
   </Ellipse.Fill>
</Ellipse>
```

Here's the Ellipse painted by the ImageBrush.

Stretch an image

If you don't set the Width or Height values of an **Image**, it is displayed with the dimensions of the image specified by the **Source**. Setting the **Width** and **Height** creates a containing rectangular area in which the image is displayed. You can specify how the image fills this containing area by using the Stretch property. The Stretch property accepts these values, which the Stretch enumeration defines:

- **None**: The image doesn't stretch to fill the output dimensions. Be careful with this Stretch setting: if the source image is larger than the containing area, your image will be clipped, and this usually isn't desirable because you don't have any control over the viewport like you do with a deliberate Clip.
- **Uniform**: The image is scaled to fit the output dimensions. But the aspect ratio of the content is preserved. This is the default value.
- **UniformToFill**: The image is scaled so that it completely fills the output area but preserves its original aspect ratio.
- **Fill**: The image is scaled to fit the output dimensions. Because the content's height and width are scaled independently, the original aspect ratio of the image might not be preserved. That is, the image might be distorted to completely fill the output area.



Crop an image

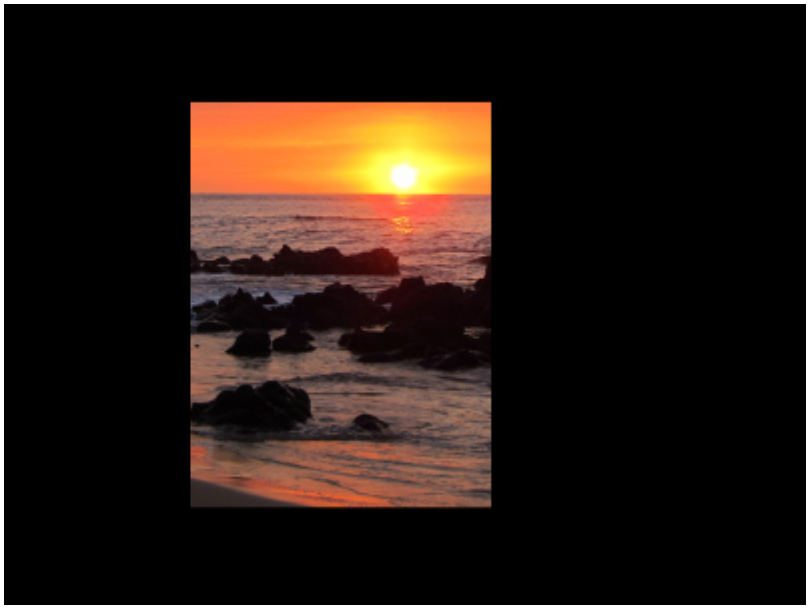
You can use the Clip property to clip an area from the image output. You set the Clip property to a Geometry. Currently, non-rectangular clipping is not supported.

The next example shows how to use a RectangleGeometry as the clip region for an image. In this example, we define an **Image** object with a height of 200. A **RectangleGeometry** defines a rectangle for the area of the image that will be displayed. The Rect property is set to "25,25,100,150", which defines a rectangle starting at position "25,25" with a width of 100 and a height of 150. Only the part of the image that is within the area of the rectangle is displayed.

XAML

```
<Image Source="sunset.jpg" Height="200">
    <Image.Clip>
        <RectangleGeometry Rect="25,25,100,150" />
    </Image.Clip>
</Image>
```

Here's the clipped image on a black background.



Apply an opacity

You can apply an Opacity to an image so that the image is rendered semi-translucent. The opacity values are from 0.0 to 1.0 where 1.0 is fully opaque and 0.0 is fully transparent. This example shows how to apply an opacity of 0.5 to an Image.

XAML

```
<Image Height="200" Source="sunset.jpg" Opacity="0.5" />
```

Here's the rendered image with an opacity of 0.5 and a black background showing through the partial opacity.

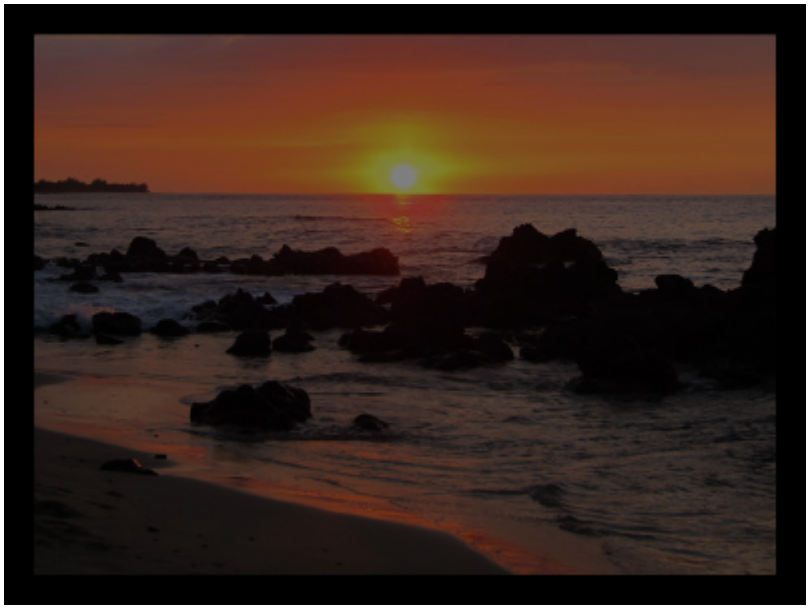


Image file formats

Image and **ImageBrush** can display these image file formats:

- Joint Photographic Experts Group (JPEG)
- Portable Network Graphics (PNG)
- bitmap (BMP)
- Graphics Interchange Format (GIF)
- Tagged Image File Format (TIFF)
- JPEG XR
- icons (ICO)

The APIs for Image, BitmapImage and BitmapSource don't include any dedicated methods for encoding and decoding of media formats. All of the encode and decode operations are built-in, and at most will surface aspects of encode or decode as part of event data for load events. If you want to do any special work with image encode or decode, which you might use if your app is doing image conversions or manipulation, you should use the APIs that are available in the Windows.Graphics.Imaging namespace. These APIs are also supported by the Windows Imaging Component (WIC) in Windows.

For more info about app resources and how to package image sources in an app, see Load images and assets tailored for scale, theme, high contrast, and others.

WriteableBitmap

A WriteableBitmap provides a BitmapSource that can be modified and that doesn't use the basic file-based decoding from the WIC. You can alter images dynamically and re-render the updated image. To define the buffer content of a **WriteableBitmap**, use the PixelBuffer property to access the buffer and use a stream or language-specific buffer type to fill it. For example code, see WriteableBitmap.

RenderTargetBitmap

The RenderTargetBitmap class can capture the XAML UI tree from a running app, and then represents a bitmap image source. After capture, that image source can be applied to other parts of the app, saved as a resource or app data by the user, or used for other scenarios. One particularly useful scenario is creating a runtime thumbnail of a XAML page for a navigation scheme. **RenderTargetBitmap** does have some limitations on the content that will appear in the captured image. For more info, see the API reference topic for RenderTargetBitmap.

Image sources and scaling

You should create your image sources at several recommended sizes, to ensure that your app looks great when Windows scales it. When specifying a **Source** for an **Image**, you can use a naming convention that will automatically reference the correct resource for the current scaling. For specifics of the naming convention and more info, see Quickstart: Using file or image resources.

For more info about how to design for scaling, see UX guidelines for layout and scaling.

Image and ImageBrush in code

It's typical to specify Image and ImageBrush elements using XAML rather than code. This is because these elements are often the output of design tools as part of a XAML UI definition.

If you define an Image or ImageBrush using code, use the default constructors, then set the relevant source property (Image.Source or ImageBrush.ImageSource). The source properties require a BitmapImage (not a URI) when you set them using code. If your source is a stream, use the SetSourceAsync method to initialize the value. If your source is a URI, which includes content in your app that uses the **ms-appx** or **ms-resource** schemes, use the BitmapImage constructor that takes a URI. You might also consider handling the ImageOpened event if there are any timing issues with retrieving or

decoding the image source, where you might need alternate content to display until the image source is available. For example code, see the WinUI Gallery sample.

> **Note**
>
> If you establish images using code, you can use automatic handling for accessing unqualified resources with current scale and culture qualifiers, or you can use ResourceManager and ResourceMap with qualifiers for culture and scale to obtain the resources directly. For more info see Resource management system.

UWP and WinUI 2

> **Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

APIs for this control exist in the Windows.UI.Xaml.Controls and Windows.UI.Xaml.Media namespaces.

- ✓ **UWP APIs:** Image class, Source property, ImageBrush class, ImageSource property
- ✓ Open the WinUI 2 Gallery app and see ImageBrushes in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles and templates for all controls.

Starting in Windows 10, version 1607, the **Image** element supports animated GIF images. When you use a **BitmapImage** as the image **Source**, you can access BitmapImage APIs to control playback of the animated GIF image. For more info, see the Remarks on the BitmapImage class page.

> **Note**

Animated GIF support is available when your app is compiled for Windows 10, version 1607 and running on version 1607 (or later). When your app is compiled for or runs on previous versions, the first frame of the GIF is shown, but it is not animated.

Inking controls

Article • 06/03/2022

There are two different controls that facilitate inking in Windows apps: InkCanvas and InkToolbar.

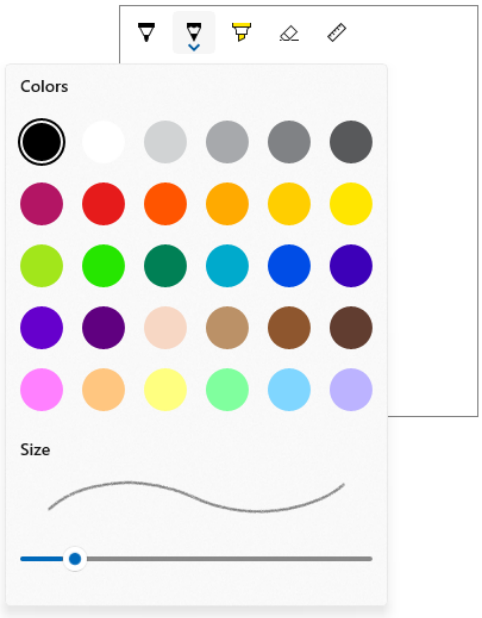
The InkCanvas control renders pen input as either an ink stroke (using default settings for color and thickness) or an erase stroke. This control is a transparent overlay that doesn't include any built-in UI for changing the default ink stroke properties.

> **Note**
>
> InkCanvas can be configured to support similar functionality for both mouse and touch input.

As the InkCanvas control does not include support for changing the default ink stroke settings, it can be paired with an InkToolbar control. The InkToolbar contains a customizable and extensible collection of buttons that activate ink-related features in an associated InkCanvas.

By default, the InkToolbar includes buttons for drawing, erasing, highlighting, and displaying a ruler. Depending on the feature, other settings and commands, such as ink color, stroke thickness, erase all ink, are provided in a flyout.

> **Note**
>
> InkToolbar supports pen and mouse input and can be configured to recognize touch input.



Is this the right control?

Use the InkCanvas when you need to enable basic inking features in your app without providing any ink settings to the user.

By default, strokes are rendered as ink when using the pen tip (a black ballpoint pen with a thickness of 2 pixels) and as an eraser when using the eraser tip. If an eraser tip is not present, the InkCanvas can be configured to process input from the pen tip as an erase stroke.

Pair the InkCanvas with an InkToolbar to provide a UI for activating ink features and setting basic ink properties such as stroke size, color, and shape of the pen tip.

> ⓘ **Note**
>
> For more extensive customization of ink stroke rendering on an InkCanvas, use the underlying **InkPresenter** object.

Ink toolbar overview

Built-in buttons

The InkToolbar includes the following built-in buttons:

Pens

- Ballpoint pen - draws a solid, opaque stroke with a circle pen tip. The stroke size is dependent on the pen pressure detected.
- Pencil - draws a soft-edged, textured, and semi-transparent stroke (useful for layered shading effects) with a circle pen tip. The stroke color (darkness) is dependent on the pen pressure detected.
- Highlighter – draws a semi-transparent stroke with a rectangle pen tip.

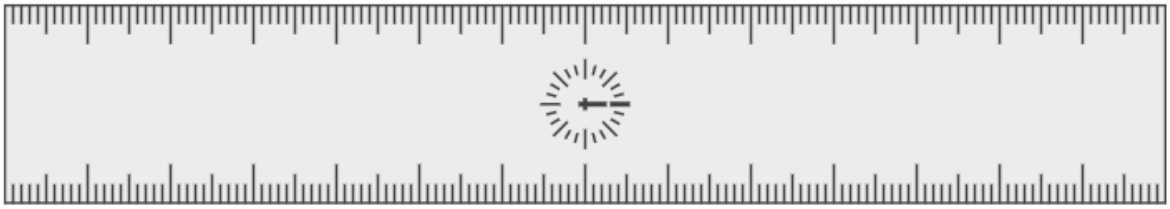
You can customize both the color palette and size attributes (min, max, default) in the flyout for each pen.

Tool

- Eraser – deletes any ink stroke touched. Note that the entire ink stroke is deleted, not just the portion under the eraser stroke.

Toggle

- Ruler – shows or hides the ruler. Drawing near the ruler edge causes the ink stroke to snap to the ruler.



Although this is the default configuration, you have complete control over which built-in buttons are included in the InkToolbar for your app.

Custom buttons

The InkToolbar consists of two distinct groups of button types:

1. A group of "tool" buttons containing the built-in drawing, erasing, and highlighting buttons. Custom pens and tools are added here.

> ⓘ **Note**
>
> Feature selection is mutually exclusive.

2. A group of "toggle" buttons containing the built-in ruler button. Custom toggles are added here.

> ⓘ **Note**

Features are not mutually exclusive and can be used concurrently with other active tools.

Depending on your application and the inking functionality required, you can add any of the following buttons (bound to your custom ink features) to the InkToolbar:

- Custom pen – a pen for which the ink color palette and pen tip properties, such as shape, rotation, and size, are defined by the host app.
- Custom tool – a non-pen tool, defined by the host app.
- Custom toggle – Sets the state of an app-defined feature to on or off. When turned on, the feature works in conjunction with the active tool.

> **Note**
>
> You cannot change the display order of the built-in buttons. The default display order is: Ballpoint pen, pencil, highlighter, eraser, and ruler. Custom pens are appended to the last default pen, custom tool buttons are added between the last pen button and the eraser button and custom toggle buttons are added after the ruler button. (Custom buttons are added in the order they are specified.)

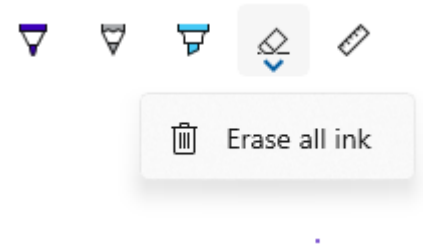
Although the InkToolbar can be a top level item, it is typically exposed through an "Inking" button or command. We recommend using EE56 glyph from the Segoe MLD2 Assets font as a top level icon.

InkToolbar Interaction

All built-in pen and tool buttons include a flyout menu where ink properties and pen tip shape and size can be set. An "extension glyph" is displayed on the button to indicate the existence of the flyout.

The flyout is shown when the button of an active tool is selected again. When the color or size is changed, the flyout is automatically dismissed and inking can be resumed. Custom pens and tools can use the default flyout or specify a custom flyout.

The eraser also has a flyout that provides the **Erase All Ink** command.



For information on customization and extensibility, check out SimpleInk sample.

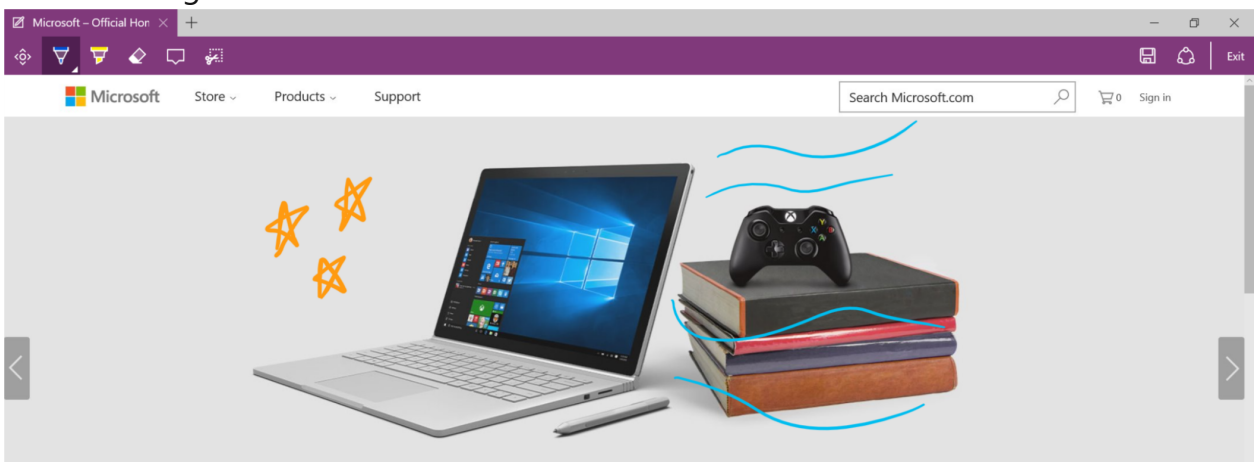
Recommendations

- The InkCanvas, and inking in general, is best experienced through an active pen. However, we recommend supporting inking with mouse and touch (including passive pen) input if required by your app.
- Use an InkToolbar control with the InkCanvas to provide basic inking features and settings. Both the InkCanvas and InkToolbar can be programmatically customized.
- The InkToolbar, and inking in general, is best experienced through an active pen. However, inking with mouse and touch can be supported if required by your app.
- If supporting inking with touch input, we recommend using the ED5F icon from the Segoe MLD2 Assets font for the toggle button, with a "Touch writing" tooltip.
- If providing stroke selection, we recommend using the EF20 icon from the Segoe MLD2 Assets font for the tool button, with a "Selection tool" tooltip.
- If using more than one InkCanvas, we recommend using a single InkToolbar to control inking across canvases.
- For best performance, we recommend altering the default flyout rather than creating a custom one for both default and custom tools.

Examples

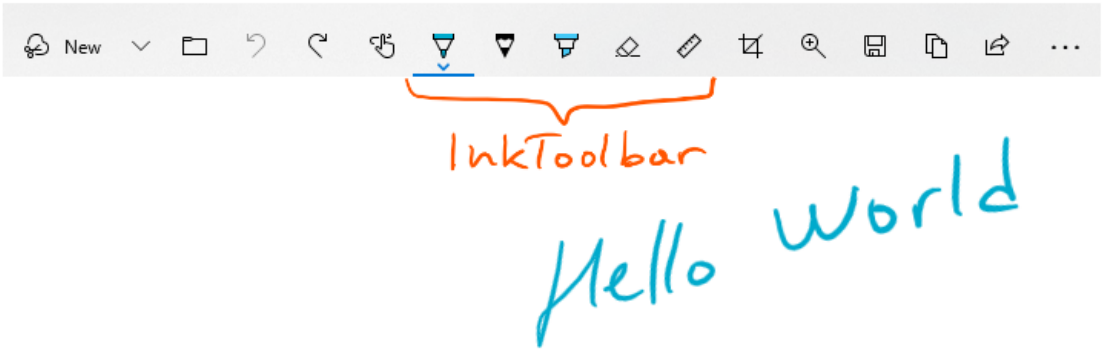
Microsoft Edge

Microsoft Edge uses the InkCanvas and InkToolbar for **Web Notes**.



Windows Ink Workspace

The InkCanvas and InkToolbar are also used for **Snip & Sketch** in the **Windows Ink Workspace**.



Create an InkCanvas and InkToolbar

- ✓ **UWP APIs:** InkCanvas class, InkToolbar class, InkPresenter class, Windows.UI.Input.Inking
- ✓ Open the WinUI 2 Gallery app and see the InkingControls in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

Adding an InkCanvas to your app requires just one line of markup:

XAML

```
<InkCanvas x:Name="myInkCanvas"/>
```

> ⓘ **Note**
>
> For detailed InkCanvas customization using InkPresenter, see the **"Pen interactions and Windows Ink in Windows apps"** article.

The InkToolbar control must be used in conjunction with an InkCanvas. Incorporating an InkToolbar (with all built-in tools) into your app requires one additional line of markup:

XAML

```
<InkToolbar TargetInkCanvas="{x:Bind myInkCanvas}"/>
```

This displays the following InkToolbar:

Get the sample code

- SimpleInk sample - Demonstrates 8 scenarios around the customization and extensibility capabilities of the InkCanvas and InkToolbar controls. Each scenario provides basic guidance on common inking situations and control implementations.
- ComplexInk sample - Demonstrates more advanced inking scenarios.
- WinUI 2 Gallery sample - See all the XAML controls in an interactive format.

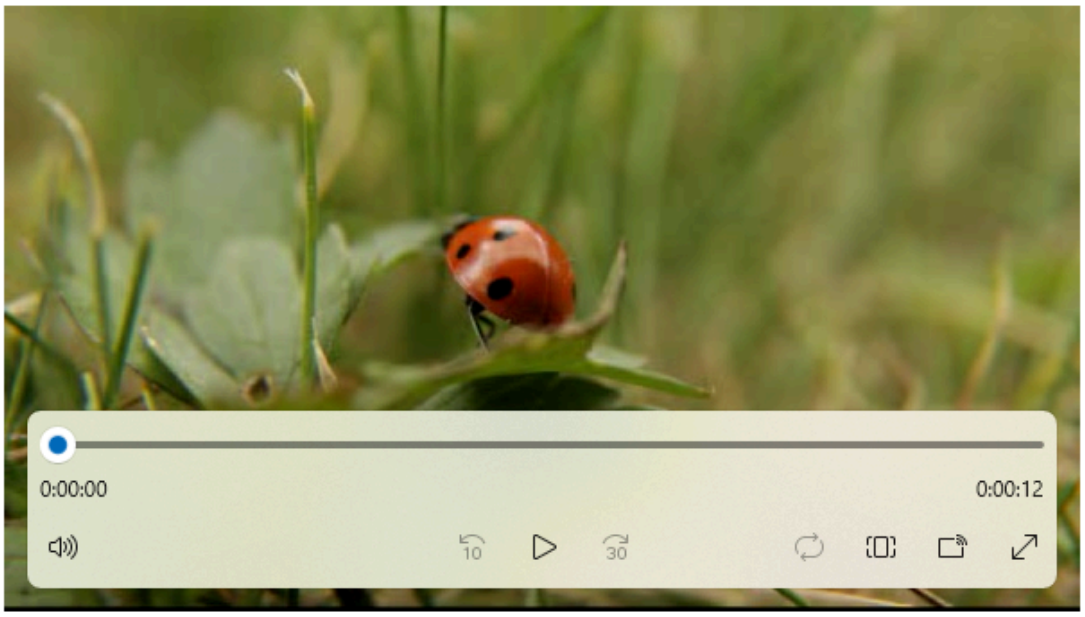
Media players

Article • 02/26/2025

Media playback involves the viewing and listening of video and audio through inline (embedded in a page or with a group of other controls) or dedicated full-screen experiences.

Users expect a basic control set, such as play/pause, skip back, skip forward, which you can modify as required (including the media player's buttons, the background of the control bar, and control arrangement or layout).



Is this the right control?

Use a media player when you want to play audio or video in your app. To display a collection of images, use a flip view.

Recommendations

The media player supports both light and dark themes, but dark theme provides a better experience for most entertainment scenarios. The dark background provides better contrast, in particular for low-light conditions, and limits the control bar from interfering in the viewing experience.

When playing video content, encourage a dedicated viewing experience by promoting full-screen mode over inline mode. The full-screen viewing experience is optimal, and options are restricted in the inline mode.

If you have the screen real estate, go with the double-row layout. It provides more space for controls than the compact single-row layout and can be easier to navigate using a variety of inputs.

The default controls have been optimized for media playback, however you have the ability to add custom options you need to the media player in order to provide the best experience for your app. Visit Create custom transport controls to learn more about adding custom controls.

Create a media player

✓ **Important APIs**: MediaPlayerElement class, MediaTransportControls class

Open the WinUI 3 Gallery app and see the MediaPlayerElement in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

Add media to your app by creating a MediaPlayerElement object in XAML and set the Source to a MediaSource that points to an audio or video file.

This XAML creates a MediaPlayerElement and sets its Source property to the URI of a video file that's local to the app. The `MediaPlayerElement` begins playing when the page loads. To suppress media from starting right away, you can set the AutoPlay property to `false`.

XAML

```
<MediaPlayerElement x:Name="mediaPlayerElement"
                    Source="ms-appx:///Videos/video1.mp4"
                    Width="400" AutoPlay="True"/>
```

This XAML creates a MediaPlayerElement with the built in transport controls enabled and the AutoPlay property set to `false.`

XAML

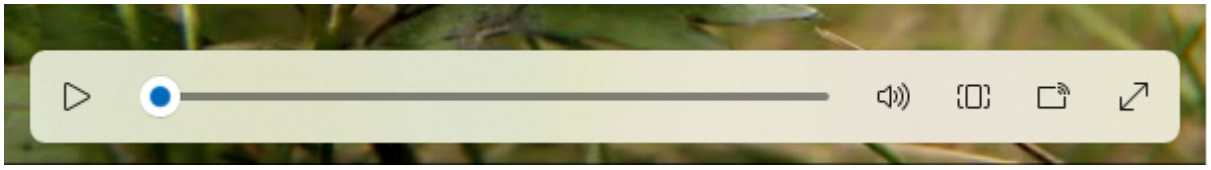
```
<MediaPlayerElement x:Name="mediaPlayerElement"
                    Source="ms-appx:///Videos/video1.mp4"
                    Width="400"
                    AutoPlay="False"
                    AreTransportControlsEnabled="True"/>
```

> **Important**
>
> Setting `MediaPlayerElement.Source` to a relative URI (ms-appx/ms-resource) only works in an app packaged with a Windows Application Packaging Project. If your app does not use a Windows Application Packaging Project, the recommended workaround is to convert the relative `ms-appx:///` URI to a fully resolved `file:///` URI. Also see the Set the media source and Open local media files sections later in this article.

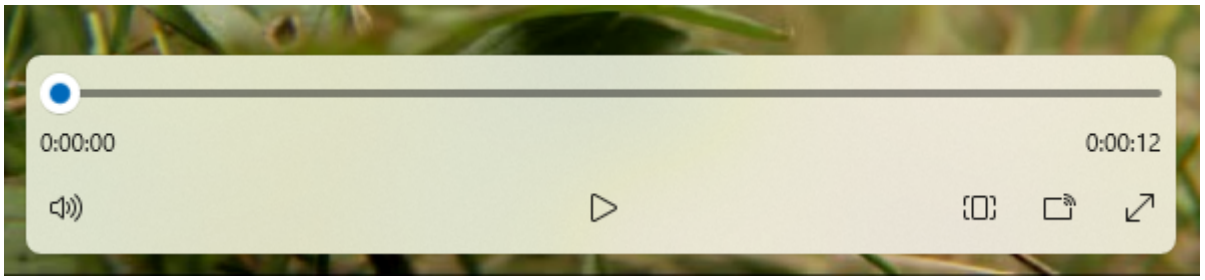
Media transport controls

MediaPlayerElement has built in transport controls that handle play, stop, pause, volume, mute, seeking/progress, closed captions, and audio track selection. To enable these controls, set AreTransportControlsEnabled to `true`. To disable them, set `AreTransportControlsEnabled` to `false`. The transport controls are represented by the MediaTransportControls class. You can use the transport controls as-is, or customize them in various ways. For more info, see the MediaTransportControls class reference and Create custom transport controls.

The transport controls support single- and double-row layouts. The first example here is a single-row layout, with the play/pause button located to the left of the media timeline. This layout is best reserved for inline media playback and compact screens.



The double-row controls layout (below) is recommended for most usage scenarios, especially on larger screens. This layout provides more space for controls and makes the timeline easier for the user to operate.



System media transport controls

MediaPlayerElement is automatically integrated with the system media transport controls. The system media transport controls are the controls that pop up when hardware media keys are pressed, such as the media buttons on keyboards. For more info, see SystemMediaTransportControls.

Set the media source

To play files on the network or files embedded with the app, set the Source property to a MediaSource with the path of the file.

> **Tip**
>
> To open files from the internet, you need to declare the **Internet (Client)** capability in your app's manifest (Package.appxmanifest). For more info about declaring capabilities, see App capability declarations.

This code attempts to set the Source property of the MediaPlayerElement defined in XAML to the path of a file entered into a TextBox.

XAML

```
<TextBox x:Name="txtFilePath" Width="400"
         FontSize="20"
         KeyUp="TxtFilePath_KeyUp"
         Header="File path"
         PlaceholderText="Enter file path"/>
```

C#

```
private void TxtFilePath_KeyUp(object sender, KeyRoutedEventArgs e)
{
    if (e.Key == Windows.System.VirtualKey.Enter)
    {
        TextBox tbPath = sender as TextBox;

        if (tbPath != null)
```

```
        {
            LoadMediaFromString(tbPath.Text);
        }
    }
}

private void LoadMediaFromString(string path)
{
    try
    {
        Uri pathUri = new Uri(path);
        mediaPlayerElement.Source = MediaSource.CreateFromUri(pathUri);
    }
    catch (Exception ex)
    {
        if (ex is FormatException)
        {
            // handle exception.
            // For example: Log error or notify user problem with file
        }
    }
}
```

To set the media source to a media file embedded in the app, initialize a Uri with the path prefixed with `ms-appx:///`, create a MediaSource with the Uri and then set the Source to the Uri. For example, for a file called **video1.mp4** that is in a **Videos** subfolder, the path would look like: `ms-appx:///Videos/video1.mp4`

> **Important**
>
> Setting `MediaPlayerElement.Source` to a relative URI (ms-appx/ms-resource) only works in an app packaged with a Windows Application Packaging Project.

This code sets the Source property of the MediaPlayerElement defined previously in XAML to `ms-appx:///Videos/video1.mp4`.

C#

```
private void LoadEmbeddedAppFile()
{
    try
    {
        Uri pathUri = new Uri("ms-appx:///Videos/video1.mp4");
        mediaPlayerElement.Source = MediaSource.CreateFromUri(pathUri);
    }
    catch (Exception ex)
    {
        if (ex is FormatException)
        {
```

```
            // handle exception.
            // For example: Log error or notify user problem with file
        }
    }
}
```

Open local media files

To open files on the local system or from OneDrive, you can use the FileOpenPicker to get the file and Source to set the media source, or you can programmatically access the user media folders.

If your app needs access without user interaction to the **Music** or **Video** folders, for example, if you are enumerating all the music or video files in the user's collection and displaying them in your app, then you need to declare the **Music Library** and **Video Library** capabilities. For more info, see Files and folders in the Music, Pictures, and Videos libraries.

The FileOpenPicker does not require special capabilities to access files on the local file system, such as the user's **Music** or **Video** folders, since the user has complete control over which file is being accessed. From a security and privacy standpoint, it is best to minimize the number of capabilities your app uses.

To open local media using FileOpenPicker

1. Call FileOpenPicker to let the user pick a media file.

   Use the FileOpenPicker class to select a media file. Set the FileTypeFilter to specify which file types the `FileOpenPicker` displays. Call PickSingleFileAsync to launch the file picker and get the file.

2. Use a MediaSource to set the chosen media file as the MediaPlayerElement.Source.

   To use the StorageFile returned from the FileOpenPicker, you need to call the CreateFromStorageFile method on MediaSource and set it as the Source of the MediaPlayerElement. Then call Play on the MediaPlayerElement.MediaPlayer to start the media.

This example shows how to use the FileOpenPicker to choose a file and set the file as the Source of a MediaPlayerElement.

XAML

```
<MediaPlayerElement x:Name="mediaPlayerElement"/>
...
```

```
<Button Content="Choose file" Click="Button_Click"/>
```

C#

```
private async void Button_Click(object sender, RoutedEventArgs e)
{
    await SetLocalMedia();
}

async private System.Threading.Tasks.Task SetLocalMedia()
{
    var openPicker = new Windows.Storage.Pickers.FileOpenPicker();
    WinRT.Interop.InitializeWithWindow.Initialize(openPicker,
WinRT.Interop.WindowNative.GetWindowHandle(this));

    openPicker.FileTypeFilter.Add(".wmv");
    openPicker.FileTypeFilter.Add(".mp4");
    openPicker.FileTypeFilter.Add(".wma");
    openPicker.FileTypeFilter.Add(".mp3");

    var file = await openPicker.PickSingleFileAsync();

    // mediaPlayerElement is a MediaPlayerElement control defined in XAML
    if (file != null)
    {
        mediaPlayerElement.Source = MediaSource.CreateFromStorageFile(file);

        mediaPlayerElement.MediaPlayer.Play();
    }
}
```

Set the poster source

You can use the PosterSource property to provide your MediaPlayerElement with a visual representation before the media is loaded. A `PosterSource` is an image, such as a screen shot, movie poster, or album art, that is displayed in place of the media. The `PosterSource` is displayed in the following situations:

- When a valid source is not set. For example, Source is not set, `Source` was set to `null`, or the source is invalid (as is the case when a MediaFailed event occurs).
- While media is loading. For example, a valid source is set, but the MediaOpened event has not occurred yet.
- When media is streaming to another device.
- When the media is audio only.

Here's a MediaPlayerElement with its Source set to an album track, and it's PosterSource set to an image of the album cover.

XAML

```
<MediaPlayerElement Source="ms-appx:///Media/Track1.mp4" PosterSource="ms-appx:///Media/AlbumCover.png"/>
```

Keep the device's screen active

Typically, a device dims the display (and eventually turns it off) to save battery life when the user is away, but video apps need to keep the screen on so the user can see the video. To prevent the display from being deactivated when user action is no longer detected, such as when an app is playing video, you can call DisplayRequest.RequestActive. The DisplayRequest class lets you tell Windows to keep the display turned on so the user can see the video.

To conserve power and battery life, you should call DisplayRequest.RequestRelease to release the display request when it is no longer required. Windows automatically deactivates your app's active display requests when your app moves off screen, and re-activates them when your app comes back to the foreground.

Here are some situations when you should release the display request:

- Video playback is paused, for example, by user action, buffering, or adjustment due to limited bandwidth.
- Playback stops. For example, the video is done playing or the presentation is over.
- A playback error has occurred. For example, network connectivity issues or a corrupted file.

To keep the screen active

1. Create a global DisplayRequest variable. Initialize it to `null`.

   C#

   ```
   private DisplayRequest appDisplayRequest = null;
   ```

2. Call RequestActive to notify Windows that the app requires the display to remain on.

3. Call RequestRelease to release the display request whenever video playback is stopped, paused, or interrupted by a playback error. When your app no longer has any active display requests, Windows saves battery life by dimming the display (and eventually turning it off) when the device is not being used.

Each MediaPlayerElement.MediaPlayer has a PlaybackSession of type MediaPlaybackSession that controls various aspects of media playback such as PlaybackRate, PlaybackState and Position. Here, you use the PlaybackStateChanged event on MediaPlayer.PlaybackSession to detect situations when you should release the display request. Then, use the NaturalVideoHeight property to determine whether an audio or video file is playing, and keep the screen active only if video is playing.

XAML

```
<MediaPlayerElement x:Name="mediaPlayerElement" Source="ms-
appx:///Videos/video1.mp4"/>
```

C#

```
public sealed partial class MainWindow : Window
{
    public DisplayRequest appDisplayRequest = null;
    // using Microsoft.UI.Dispatching;
    private DispatcherQueue dispatcherQueue =
DispatcherQueue.GetForCurrentThread();

    public MainWindow()
    {
        this.InitializeComponent();
        mediaPlayerElement.MediaPlayer.PlaybackSession.PlaybackStateChanged
+=
            PlaybackSession_PlaybackStateChanged;
    }

    private void PlaybackSession_PlaybackStateChanged(MediaPlaybackSession
sender, object args)
    {
        MediaPlaybackSession playbackSession = sender as
MediaPlaybackSession;
        if (playbackSession != null && playbackSession.NaturalVideoHeight !=
0)
        {
            if (playbackSession.PlaybackState == MediaPlaybackState.Playing)
            {
                if (appDisplayRequest is null)
                {

dispatcherQueue.TryEnqueue(DispatcherQueuePriority.Normal, () =>
                    {
                        appDisplayRequest = new DisplayRequest();
                        appDisplayRequest.RequestActive();
                    });
                }
            }
            else // PlaybackState is Buffering, None, Opening, or Paused.
            {
```

```
                if (appDisplayRequest is not null)
                {
                    appDisplayRequest.RequestRelease();
                    appDisplayRequest = null;
                }
            }
        }
    }
}
```

Control the media player programmatically

MediaPlayerElement provides numerous properties, methods, and events for controlling audio and video playback through the MediaPlayerElement.MediaPlayer property. For a full listing of properties, methods, and events, see the MediaPlayer reference page.

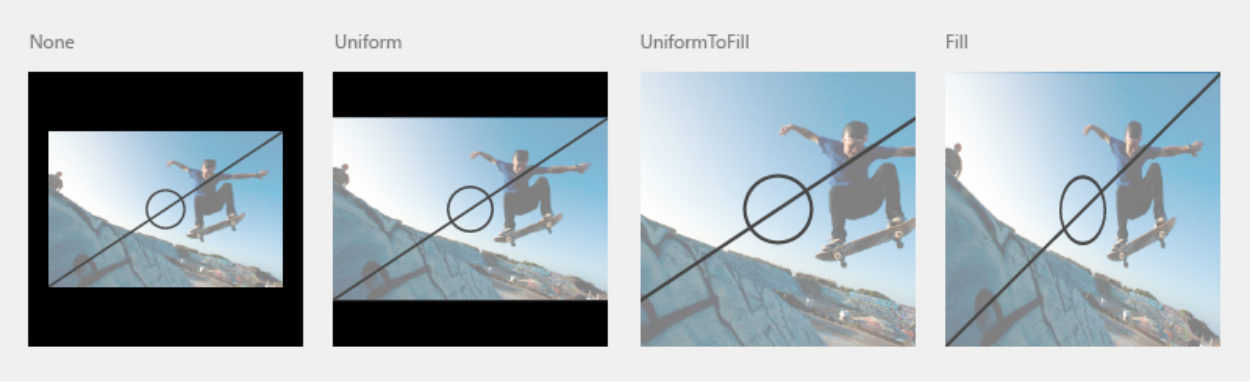
Advanced media playback scenarios

For more complex media playback scenarios like playing a playlist, switching between audio languages, or creating custom metadata tracks, set the MediaPlayerElement.Source to a MediaPlaybackItem or a MediaPlaybackList. See the Media playback page for more information on how to enable various advanced media functionality.

Resize and stretch video

Use the Stretch property to change how the video content and/or the PosterSource fills the container it's in. This resizes and stretches the video depending on the Stretch value. The `Stretch` states are similar to picture size settings on many TV sets. You can hook this up to a button and allow the user to choose which setting they prefer.

- None displays the native resolution of the content in its original size.This can result in some of the video being cropped or black bars at the edges of the video.
- Uniform fills up as much of the space as possible while preserving the aspect ratio and the video content. This can result in horizontal or vertical black bars at the edges of the video. This is similar to wide-screen modes.
- UniformToFill fills up the entire space while preserving the aspect ratio. This can result in some of the video being cropped. This is similar to full-screen modes.
- Fill fills up the entire space, but does not preserve the aspect ratio. None of video is cropped, but stretching may occur. This is similar to stretch modes.



Here, an AppBarButton is used to cycle through the Stretch options. A `switch` statement checks the current state of the Stretch property and sets it to the next value in the `Stretch` enumeration. This lets the user cycle through the different stretch states.

XAML

```
<AppBarButton Icon="Trim"
              Label="Resize Video"
              Click="PictureSize_Click" />
```

C#

```
private void PictureSize_Click(object sender, RoutedEventArgs e)
{
    switch (mediaPlayerElement.Stretch)
    {
        case Stretch.Fill:
            mediaPlayerElement.Stretch = Stretch.None;
            break;
        case Stretch.None:
            mediaPlayerElement.Stretch = Stretch.Uniform;
            break;
        case Stretch.Uniform:
            mediaPlayerElement.Stretch = Stretch.UniformToFill;
            break;
        case Stretch.UniformToFill:
            mediaPlayerElement.Stretch = Stretch.Fill;
            break;
        default:
            break;
    }
}
```

Enable low-latency playback

Set the RealTimePlayback property to `true` on a MediaPlayerElement.MediaPlayer to enable the media player element to reduce the initial latency for playback. This is critical

for two-way communications apps, and can be applicable to some gaming scenarios. Be aware that this mode is more resource intensive and less power-efficient.

This example creates a MediaPlayerElement and sets RealTimePlayback to `true`.

```
C#

MediaPlayerElement mediaPlayerElement = new MediaPlayerElement();
mediaPlayerElement.MediaPlayer.RealTimePlayback = true;
```

UWP and WinUI 2

> **ⓘ Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

APIs for this control exist in the Windows.UI.Xaml.Controls namespace.

- ✓ **UWP APIs:** MediaPlayerElement class, MediaTransportControls class
- ✓ Open the WinUI 2 Gallery app and see the MediaPlayerElement in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles and templates for all controls. WinUI 2.2 or later includes a new template for this control that uses rounded corners. For more info, see Corner radius.

If you are designing for the 10-foot experience, go with the double-row layout. It provides more space for controls than the compact single-row layout and it is easier to navigate using a gamepad for 10-foot. See the Designing for Xbox and TV article for more information about optimizing your application for the 10-foot experience.

`MediaPlayerElement` is only available in Windows 10, version 1607 and later. If you are developing an app for an earlier version of Windows 10, you need to use the

MediaElement control instead. All recommendations made here apply to `MediaElement` as well.

Create custom transport controls

Article • 05/13/2022

MediaPlayerElement has customizable XAML transport controls to manage control of audio and video content within a Windows app. Here, we demonstrate how to customize the MediaTransportControls template. We'll show you how to work with the overflow menu, add a custom button and modify the slider.

> **Important APIs**: MediaPlayerElement, MediaPlayerElement.AreTransportControlsEnabled, MediaTransportControls

Before starting, you should be familiar with the MediaPlayerElement and the MediaTransportControls classes. For more info, see the MediaPlayerElement control guide.

> **Tip**
>
> The examples in this topic are based on the **Media Transport Controls sample**. You can download the sample to view and run the completed code.

> **Note**
>
> **MediaPlayerElement** is only available in Windows 10, version 1607 and later. If you are developing an app for an earlier version of Windows 10 you will need to use MediaElement instead. All of the examples on this page work with **MediaElement** as well.

When should you customize the template?

MediaPlayerElement has built-in transport controls that are designed to work well without modification in most video and audio playback apps. They're provided by the MediaTransportControls class and include buttons to play, stop, and navigate media, adjust volume, toggle full screen, cast to a second device, enable captions, switch audio tracks, and adjust the playback rate. MediaTransportControls has properties that let you control whether each button is shown and enabled. You can also set the IsCompact property to specify whether the controls are shown in one row or two.

However, there may be scenarios where you need to further customize the look of the control or change its behavior. Here are some examples:

- Change the icons, slider behavior, and colors.
- Move less commonly used command buttons into an overflow menu.
- Change the order in which commands drop out when the control is resized.
- Provide a command button that's not in the default set.

> **Note**
>
> The buttons visible on screen will drop out of the built-in transport controls in a predefined order if there is not enough room on screen. To change this ordering or put commands that don't fit into an overflow menu, you will need to customize the controls.

You can customize the appearance of the control by modifying the default template. To modify the control's behavior or add new commands, you can create a custom control that's derived from MediaTransportControls.

> **Tip**
>
> Customizable control templates are a powerful feature of the XAML platform, but there are also consequences that you should take into consideration. When you customize a template, it becomes a static part of your app and therefore will not receive any platform updates that are made to the template by Microsoft. If template updates are made by Microsoft, you should take the new template and re-modify it in order to get the benefits of the updated template.

Template structure

The **ControlTemplate** is part of the default style. You can copy this default style into your project to modify it. The ControlTemplate is divided into sections similar to other XAML control templates.

- The first section of the template contains the **Style** definitions for the various components of the MediaTransportControls.
- The second section defines the various visual states that are used by the MediaTransportControls.
- The third section contains the **Grid** that holds that various MediaTransportControls elements together and defines how the components are laid out.

> **Note**
>
> For more info about modifying templates, see Control templates. You can use a text editor or similar editors in your IDE to open the XAML files in (*Program Files*)\Windows Kits\10\DesignTime\CommonConfiguration\Neutral\UAP\(*SDK version*)\Generic. The default style and template for each control is defined in the **generic.xaml** file. You can find the MediaTransportControls template in generic.xaml by searching for "MediaTransportControls".

In the following sections, you learn how to customize several of the main elements of the transport controls:

- **Slider**: allows a user to scrub through their media and also displays progress
- **CommandBar**: contains all of the buttons. For more info, see the Anatomy section of the MediaTransportControls reference topic.

Customize the transport controls

If you want to modify only the appearance of the MediaTransportControls, you can create a copy of the default control style and template, and modify that. However, if you also want to add to or modify the functionality of the control, you need to create a new class that derives from MediaTransportControls.

Re-template the control

To customize the MediaTransportControls default style and template

1. Copy the default style from MediaTransportControls styles and templates into a ResourceDictionary in your project.
2. Give the Style an x:Key value to identify it, like this.

XAML

```
<Style TargetType="MediaTransportControls" x:Key="myTransportControlsStyle">
    <!-- Style content ... -->
</Style>
```

3. Add a MediaPlayerElement with MediaTransportControls to your UI.
4. Set the Style property of the MediaTransportControls element to your custom Style resource, as shown here.

XAML

```
<MediaPlayerElement AreTransportControlsEnabled="True">
    <MediaPlayerElement.TransportControls>
        <MediaTransportControls Style="{StaticResource
myTransportControlsStyle}"/>
    </MediaPlayerElement.TransportControls>
</MediaPlayerElement>
```

For more info about modifying styles and templates, see Styling controls and Control templates.

Create a derived control

To add to or modify the functionality of the transport controls, you must create a new class that's derived from MediaTransportControls. A derived class called `CustomMediaTransportControls` is shown in the Media Transport Controls sample and the remaining examples on this page.

To create a new class derived from MediaTransportControls

1. Add a new class file to your project.
    - In Visual Studio, select Project > Add Class. The Add New Item dialog opens.
    - In the Add New Item dialog, enter a name for the class file, then click Add. (In the Media Transport Controls sample, the class is named `CustomMediaTransportControls`.)
2. Modify the class code to derive from the MediaTransportControls class.

C#

```
public sealed class CustomMediaTransportControls : MediaTransportControls
{
}
```

3. Copy the default style for **MediaTransportControls** into a ResourceDictionary in your project. This is the style and template you modify. (In the Media Transport Controls sample, a new folder called "Themes" is created, and a ResourceDictionary file called generic.xaml is added to it.)
4. Change the **TargetType** of the style to the new custom control type. (In the sample, the TargetType is changed to `local:CustomMediaTransportControls`.)

XAML

```
xmlns:local="using:CustomMediaTransportControls">
...
<Style TargetType="local:CustomMediaTransportControls">
```

5. Set the **DefaultStyleKey** of your custom class. This tells your custom class to use a Style with a TargetType of `local:CustomMediaTransportControls`.

C#

```
public sealed class CustomMediaTransportControls : MediaTransportControls
{
    public CustomMediaTransportControls()
    {
        this.DefaultStyleKey = typeof(CustomMediaTransportControls);
    }
}
```

6. Add a **MediaPlayerElement** to your XAML markup and add the custom transport controls to it. One thing to note is that the APIs to hide, show, disable, and enable the default buttons still work with a customized template.

XAML

```
<MediaPlayerElement Name="MediaPlayerElement1"
AreTransportControlsEnabled="True" Source="video.mp4">
    <MediaPlayerElement.TransportControls>
        <local:CustomMediaTransportControls x:Name="customMTC"

IsFastForwardButtonVisible="True"
                                            IsFastForwardEnabled="True"
                                            IsFastRewindButtonVisible="True"
                                            IsFastRewindEnabled="True"

IsPlaybackRateButtonVisible="True"
                                            IsPlaybackRateEnabled="True"
                                            IsCompact="False">
        </local:CustomMediaTransportControls>
    </MediaPlayerElement.TransportControls>
</MediaPlayerElement>
```

You can now modify the control style and template to update the look of your custom control, and the control code to update its behavior.

Working with the overflow menu

You can move MediaTransportControls command buttons into an overflow menu, so that less commonly used commands are hidden until the user needs them.

In the MediaTransportControls template, the command buttons are contained in a **CommandBar** element. The command bar has the concept of primary and secondary commands. The primary commands are the buttons that appear in the control by default and are always visible (unless you disable the button, hide the button or there is not enough room). The secondary commands are shown in an overflow menu that appears when a user clicks the ellipsis (...) button. For more info, see the App bars and command bars article.

To move an element from the command bar primary commands to the overflow menu, you need to edit the XAML control template.

To move a command to the overflow menu:

1. In the control template, find the CommandBar element named `MediaControlsCommandBar`.
2. Add a **SecondaryCommands** section to the XAML for the CommandBar. Put it after the closing tag for the **PrimaryCommands**.

XAML

```
<CommandBar x:Name="MediaControlsCommandBar" ... >
  <CommandBar.PrimaryCommands>
...
    <AppBarButton x:Name='PlaybackRateButton'
                  Style='{StaticResource AppBarButtonStyle}'
                  MediaTransportControlsHelper.DropoutOrder='4'
                  Visibility='Collapsed'>
      <AppBarButton.Icon>
        <FontIcon Glyph="&#xEC57;"/>
      </AppBarButton.Icon>
    </AppBarButton>
...
  </CommandBar.PrimaryCommands>
<!-- Add secondary commands (overflow menu) here -->
  <CommandBar.SecondaryCommands>
    ...
  </CommandBar.SecondaryCommands>
</CommandBar>
```

3. To populate the menu with commands, cut and paste the XAML for the desired **AppBarButton** objects from the PrimaryCommands to the SecondaryCommands. In this example, we move the `PlaybackRateButton` to the overflow menu.

4. Add a label to the button and remove the styling information, as shown here. Because the overflow menu is comprised of text buttons, you must add a text label to the button and also remove the style that sets the height and width of the button. Otherwise, it won't appear correctly in the overflow menu.

XAML

```
<CommandBar.SecondaryCommands>
    <AppBarButton x:Name='PlaybackRateButton'
                  Label='Playback Rate'>
    </AppBarButton>
</CommandBar.SecondaryCommands>
```

> **Important**
>
> You must still make the button visible and enable it in order to use it in the overflow menu. In this example, the PlaybackRateButton element isn't visible in the overflow menu unless the IsPlaybackRateButtonVisible property is true. It's not enabled unless the IsPlaybackRateEnabled property is true. Setting these properties is shown in the previous section.

Adding a custom button

One reason you might want to customize MediaTransportControls is to add a custom command to the control. Whether you add it as a primary command or a secondary command, the procedure for creating the command button and modifying its behavior is the same. In the Media Transport Controls sample, a "rating" button is added to the primary commands.

To add a custom command button

1. Create an AppBarButton object and add it to the CommandBar in the control template.

XAML

```
<AppBarButton x:Name="LikeButton"
              Icon="Like"
              Style="{StaticResource AppBarButtonStyle}"
              MediaTransportControlsHelper.DropoutOrder="3"
              VerticalAlignment="Center" />
```

You must add it to the CommandBar in the appropriate location. (For more information, see the Working with the overflow menu section.) How it's positioned in the UI is determined by where the button is in the markup. For example, if you want this button to appear as the last element in the primary commands, add it at the very end of the primary commands list.

You can also customize the icon for the button. For more information, see the **AppBarButton** reference.

2. In the **OnApplyTemplate** override, get the button from the template and register a handler for its **Click** event. This code goes in the `CustomMediaTransportControls` class.

C#

```
public sealed class CustomMediaTransportControls :  MediaTransportControls
{
    // ...

    protected override void OnApplyTemplate()
    {
        // Find the custom button and create an event handler for its Click
event.
        var likeButton = GetTemplateChild("LikeButton") as Button;
        likeButton.Click += LikeButton_Click;
        base.OnApplyTemplate();
    }

    //...
}
```

3. Add code to the Click event handler to perform the action that occurs when the button is clicked. Here's the complete code for the class.

C#

```
public sealed class CustomMediaTransportControls : MediaTransportControls
{
    public event EventHandler< EventArgs> Liked;

    public CustomMediaTransportControls()
    {
        this.DefaultStyleKey = typeof(CustomMediaTransportControls);
    }

    protected override void OnApplyTemplate()
    {
        // Find the custom button and create an event handler for its Click
event.
```

```
        var likeButton = GetTemplateChild("LikeButton") as Button;
        likeButton.Click += LikeButton_Click;
        base.OnApplyTemplate();
    }

    private void LikeButton_Click(object sender, RoutedEventArgs e)
    {
        // Raise an event on the custom control when 'like' is clicked.
        var handler = Liked;
        if (handler != null)
        {
            handler(this, EventArgs.Empty);
        }
    }
}
```

Modifying the slider

The "seek" control of the MediaTransportControls is provided by a **Slider** element. One way you can customize it is to change the granularity of the seek behavior.

The default seek slider is divided into 100 parts, so the seek behavior is limited to that many sections. You can change the granularity of the seek slider by getting the Slider from the XAML visual tree in your **MediaOpened** event handler on **MediaPlayerElement.MediaPlayer**. This example shows how to use **VisualTreeHelper** to get a reference to the Slider, then change the default step frequency of the slider from 1% to 0.1% (1000 steps) if the media is longer than 120 minutes. The MediaPlayerElement is named `MediaPlayerElement1`.

C#

```
protected override void OnNavigatedTo(NavigationEventArgs e)
{
  MediaPlayerElement1.MediaPlayer.MediaOpened +=
MediaPlayerElement_MediaPlayer_MediaOpened;
  base.OnNavigatedTo(e);
}

private void MediaPlayerElement_MediaPlayer_MediaOpened(object sender,
RoutedEventArgs e)
{
  FrameworkElement transportControlsTemplateRoot =
(FrameworkElement)VisualTreeHelper.GetChild(MediaPlayerElement1.TransportCon
trols, 0);
  Slider sliderControl =
(Slider)transportControlsTemplateRoot.FindName("ProgressSlider");
  if (sliderControl != null &&
MediaPlayerElement1.NaturalDuration.TimeSpan.TotalMinutes > 120)
  {
```

```
    // Default is 1%. Change to 0.1% for more granular seeking.
    sliderControl.StepFrequency = 0.1;
  }
}
```

Draw shapes

Article • 02/26/2025

Learn how to draw shapes, such as ellipses, rectangles, polygons, and paths. The **Path** class is the way to visualize a fairly complex vector-based drawing language in a XAML UI; for example, you can draw Bezier curves.

✓ **Important APIs**: Path class, Microsoft.UI.Xaml.Shapes namespace, Microsoft.UI.Xaml.Media namespace

Two sets of classes define a region of space in XAML UI: **Shape** classes and **Geometry** classes. The main difference between these classes is that a **Shape** has a brush associated with it and can be rendered to the screen, and a **Geometry** simply defines a region of space and is not rendered unless it helps contribute information to another UI property. You can think of a **Shape** as a **UIElement** with its boundary defined by a **Geometry**. This topic covers mainly the **Shape** classes.

The **Shape** classes are **Line**, **Ellipse**, **Rectangle**, **Polygon**, **Polyline**, and **Path**. **Path** is interesting because it can define an arbitrary geometry, and the **Geometry** class is involved here because that's one way to define the parts of a **Path**.

Fill and Stroke for shapes

For a **Shape** to render to the app canvas, you must associate a **Brush** with it. Set the **Fill** property of the **Shape** to the **Brush** you want. For more info about brushes, see Using brushes.

A **Shape** can also have a **Stroke**, which is a line that is drawn around the shape's perimeter. A **Stroke** also requires a **Brush** that defines its appearance, and should have a non-zero value for **StrokeThickness**. **StrokeThickness** is a property that defines the perimeter's thickness around the shape edge. If you don't specify a **Brush** value for **Stroke**, or if you set **StrokeThickness** to 0, then the border around the shape is not drawn.

Ellipse

An **Ellipse** is a shape with a curved perimeter. To create a basic **Ellipse**, specify a **Width**, **Height**, and a **Brush** for the **Fill**.

The next example creates an **Ellipse** with a **Width** of 200 and a **Height** of 200, and uses a **SteelBlue** colored **SolidColorBrush** as its **Fill**.

XAML

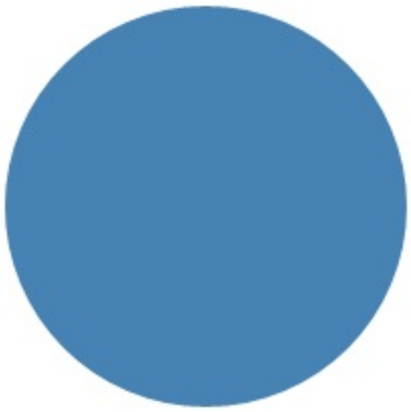
```
<Ellipse Fill="SteelBlue" Height="200" Width="200" />
```

C#

```
var ellipse1 = new Ellipse();
ellipse1.Fill = new SolidColorBrush(Colors.SteelBlue);
ellipse1.Width = 200;
ellipse1.Height = 200;

// When you create a XAML element in code, you have to add
// it to the XAML visual tree. This example assumes you have
// a panel named 'layoutRoot' in your XAML file, like this:
// <Grid x:Name="layoutRoot>
layoutRoot.Children.Add(ellipse1);
```

Here's the rendered **Ellipse**.



In this case the **Ellipse** is what most people would consider a circle, but that's how you declare a circle shape in XAML: use an **Ellipse** with equal **Width** and **Height**.

When an **Ellipse** is positioned in a UI layout, its size is assumed to be the same as a rectangle with that **Width** and **Height**; the area outside the perimeter does not have rendering but still is part of its layout slot size.

A set of 6 **Ellipse** elements are part of the control template for the **ProgressRing** control, and 2 concentric **Ellipse** elements are part of a **RadioButton**.

Rectangle

A **Rectangle** is a four-sided shape with its opposite sides being equal. To create a basic **Rectangle**, specify a **Width**, a **Height**, and a **Fill**.

You can round the corners of a **Rectangle**. To create rounded corners, specify a value for the **RadiusX** and **RadiusY** properties. These properties specify the x-axis and y-axis of an ellipse that defines the curve of the corners. The maximum allowed value of **RadiusX** is the **Width** divided by two and the maximum allowed value of **RadiusY** is the **Height** divided by two.

The next example creates a **Rectangle** with a **Width** of 200 and a **Height** of 100. It uses a **Blue** value of **SolidColorBrush** for its **Fill** and a **Black** value of **SolidColorBrush** for its **Stroke**. We set the **StrokeThickness** to 3. We set the **RadiusX** property to 50 and the **RadiusY** property to 10, which gives the **Rectangle** rounded corners.

XAML

```
<Rectangle Fill="Blue"
           Width="200"
           Height="100"
           Stroke="Black"
           StrokeThickness="3"
           RadiusX="50"
           RadiusY="10" />
```

C#

```
var rectangle1 = new Rectangle();
rectangle1.Fill = new SolidColorBrush(Colors.Blue);
rectangle1.Width = 200;
rectangle1.Height = 100;
rectangle1.Stroke = new SolidColorBrush(Colors.Black);
rectangle1.StrokeThickness = 3;
rectangle1.RadiusX = 50;
rectangle1.RadiusY = 10;

// When you create a XAML element in code, you have to add
// it to the XAML visual tree. This example assumes you have
// a panel named 'layoutRoot' in your XAML file, like this:
// <Grid x:Name="layoutRoot>
layoutRoot.Children.Add(rectangle1);
```

Here's the rendered **Rectangle**.

There are some scenarios for UI definitions where instead of using a **Rectangle**, a **Border** might be more appropriate. If your intention is to create a rectangle shape around other content, it might be better to use **Border** because it can have child content and will automatically size around that content, rather than using the fixed dimensions for height and width like **Rectangle** does. A **Border** also has the option of having rounded corners if you set the **CornerRadius** property.

On the other hand, a **Rectangle** is probably a better choice for control composition. A **Rectangle** shape is seen in many control templates because it's used as a "FocusVisual" part for focusable controls. Whenever the control is in a "Focused" visual state, this rectangle is made visible, in other states it's hidden.

Polygon

A **Polygon** is a shape with a boundary defined by an arbitrary number of points. The boundary is created by connecting a line from one point to the next, with the last point connected to the first point. The **Points** property defines the collection of points that make up the boundary. In XAML, you define the points with a comma-separated list. In code-behind you use a **PointCollection** to define the points and you add each individual point as a **Point** value to the collection.

You don't need to explicitly declare the points such that the start point and end point are both specified as the same **Point** value. The rendering logic for a **Polygon** assumes that you are defining a closed shape and will connect the end point to the start point implicitly.

The next example creates a **Polygon** with 4 points set to `(10,200)`, `(60,140)`, `(130,140)`, and `(180,200)`. It uses a **LightBlue** value of **SolidColorBrush** for its **Fill**, and has no value for **Stroke** so it has no perimeter outline.

XAML

```
<Polygon Fill="LightBlue"
         Points="10,200,60,140,130,140,180,200" />
```

C#

```
var polygon1 = new Polygon();
polygon1.Fill = new SolidColorBrush(Colors.LightBlue);

var points = new PointCollection();
points.Add(new Windows.Foundation.Point(10, 200));
points.Add(new Windows.Foundation.Point(60, 140));
points.Add(new Windows.Foundation.Point(130, 140));
```

```
points.Add(new Windows.Foundation.Point(180, 200));
polygon1.Points = points;

// When you create a XAML element in code, you have to add
// it to the XAML visual tree. This example assumes you have
// a panel named 'layoutRoot' in your XAML file, like this:
// <Grid x:Name="layoutRoot>
layoutRoot.Children.Add(polygon1);
```

Here's the rendered Polygon.

> **Tip**
>
> A Point value is often used as a type in XAML for scenarios other than declaring the vertices of shapes. For example, a **Point** is part of the event data for touch events, so you can know exactly where in a coordinate space the touch action occurred. For more info about **Point** and how to use it in XAML or code, see the API reference topic for Point.

Line

A Line is simply a line drawn between two points in coordinate space. A **Line** ignores any value provided for Fill, because it has no interior space. For a **Line**, make sure to specify values for the Stroke and StrokeThickness properties, because otherwise the **Line** won't render.

You don't use Point values to specify a Line shape, instead you use discrete Double values for X1, Y1, X2 and Y2. This enables minimal markup for horizontal or vertical lines. For example, `<Line Stroke="Red" X2="400"/>` defines a horizontal line that is 400 pixels long. The other X,Y properties are 0 by default, so in terms of points this XAML would draw a line from `(0,0)` to `(400,0)`. You could then use a TranslateTransform to move the entire **Line**, if you wanted it to start at a point other than (0,0).

XAML

```
<Line Stroke="Red" X2="400"/>
```

C#

```
var line1 = new Line();
line1.Stroke = new SolidColorBrush(Colors.Red);
line1.X2 = 400;

// When you create a XAML element in code, you have to add
// it to the XAML visual tree. This example assumes you have
// a panel named 'layoutRoot' in your XAML file, like this:
// <Grid x:Name="layoutRoot>
layoutRoot.Children.Add(line1);
```

Polyline

A **Polyline** is similar to a **Polygon** in that the boundary of the shape is defined by a set of points, except the last point in a **Polyline** is not connected to the first point.

> ⓘ **Note**
>
> You could explicitly have an identical start point and end point in the **Points** set for the **Polyline**, but in that case you probably could have used a **Polygon** instead.

If you specify a **Fill** of a **Polyline**, the **Fill** paints the interior space of the shape, even if the start point and end point of the **Points** set for the **Polyline** do not intersect. If you do not specify a **Fill**, then the **Polyline** is similar to what would have rendered if you had specified several individual **Line** elements where the start points and end points of consecutive lines intersected.

As with a **Polygon**, the **Points** property defines the collection of points that make up the boundary. In XAML, you define the points with a comma-separated list. In code-behind, you use a **PointCollection** to define the points and you add each individual point as a **Point** structure to the collection.

This example creates a **Polyline** with four points set to `(10,200)`, `(60,140)`, `(130,140)`, and `(180,200)`. A **Stroke** is defined but not a **Fill**.

XAML

```
<Polyline Stroke="Black"
          StrokeThickness="4"
          Points="10,200,60,140,130,140,180,200" />
```

C#

```
var polyline1 = new Polyline();
polyline1.Stroke = new SolidColorBrush(Colors.Black);
polyline1.StrokeThickness = 4;

var points = new PointCollection();
points.Add(new Windows.Foundation.Point(10, 200));
points.Add(new Windows.Foundation.Point(60, 140));
points.Add(new Windows.Foundation.Point(130, 140));
points.Add(new Windows.Foundation.Point(180, 200));
polyline1.Points = points;

// When you create a XAML element in code, you have to add
// it to the XAML visual tree. This example assumes you have
// a panel named 'layoutRoot' in your XAML file, like this:
// <Grid x:Name="layoutRoot>
layoutRoot.Children.Add(polyline1);
```

Here's the rendered Polyline. Notice that the first and last points are not connected by the Stroke outline as they are in a Polygon.

Path

A Path is the most versatile Shape because you can use it to define an arbitrary geometry. But with this versatility comes complexity. Let's now look at how to create a basic **Path** in XAML.

You define the geometry of a path with the Data property. There are two techniques for setting **Data**:

- You can set a string value for Data in XAML. In this form, the **Path.Data** value is consuming a serialization format for graphics. You typically don't text-edit this value in string form after it is first established. Instead, you use design tools that enable you to work in a design or drawing metaphor on a surface. Then you save or export the output, and this gives you a XAML file or XAML string fragment with **Path.Data** information.
- You can set the Data property to a single Geometry object. This can be done in code or in XAML. That single **Geometry** is typically a GeometryGroup, which acts as a container that can composite multiple geometry definitions into a single object for purposes of the object model. The most common reason for doing this

is because you want to use one or more of the curves and complex shapes that can be defined as Segments values for a PathFigure, for example BezierSegment.

This example shows a Path that might have resulted from using Blend for Visual Studio to produce just a few vector shapes and then saving the result as XAML. The total **Path** consists of a Bezier curve segment and a line segment. The example is mainly intended to give you some examples of what elements exist in the Path.Data serialization format and what the numbers represent.

This Data begins with the move command, indicated by "M", which establishes an absolute start point for the path.

The first segment is a cubic Bezier curve that begins at `(100,200)` and ends at `(400,175)`, which is drawn by using the two control points `(100,25)` and `(400,350)`. This segment is indicated by the "C" command in the Data attribute string.

The second segment begins with an absolute horizontal line command "H", which specifies a line drawn from the preceding subpath endpoint `(400,175)` to a new endpoint `(280,175)`. Because it's a horizontal line command, the value specified is an x-coordinate.

XAML

```
<Path Stroke="DarkGoldenRod"
      StrokeThickness="3"
      Data="M 100,200 C 100,25 400,350 400,175 H 280" />
```

Here's the rendered Path.

The next example shows a usage of the other technique we discussed: a GeometryGroup with a PathGeometry. This example exercises some of the contributing geometry types that can be used as part of a **PathGeometry**: PathFigure and the various elements that can be a segment in PathFigure.Segments.

XAML

```
<Path Stroke="Black" StrokeThickness="1" Fill="#CCCCFF">
    <Path.Data>
        <GeometryGroup>
```

```
            <RectangleGeometry Rect="50,5 100,10" />
            <RectangleGeometry Rect="5,5 95,180" />
            <EllipseGeometry Center="100, 100" RadiusX="20" RadiusY="30"/>
            <RectangleGeometry Rect="50,175 100,10" />
            <PathGeometry>
                <PathGeometry.Figures>
                    <PathFigureCollection>
                        <PathFigure IsClosed="true" StartPoint="50,50">
                            <PathFigure.Segments>
                                <PathSegmentCollection>
                                    <BezierSegment Point1="75,300"
Point2="125,100" Point3="150,50"/>
                                    <BezierSegment Point1="125,300"
Point2="75,100"  Point3="50,50"/>
                                </PathSegmentCollection>
                            </PathFigure.Segments>
                        </PathFigure>
                    </PathFigureCollection>
                </PathGeometry.Figures>
            </PathGeometry>
        </GeometryGroup>
    </Path.Data>
</Path>
```

C#

```
var path1 = new Microsoft.UI.Xaml.Shapes.Path();
path1.Fill = new SolidColorBrush(Windows.UI.Color.FromArgb(255, 204, 204,
255));
path1.Stroke = new SolidColorBrush(Colors.Black);
path1.StrokeThickness = 1;

var geometryGroup1 = new GeometryGroup();
var rectangleGeometry1 = new RectangleGeometry();
rectangleGeometry1.Rect = new Rect(50, 5, 100, 10);
var rectangleGeometry2 = new RectangleGeometry();
rectangleGeometry2.Rect = new Rect(5, 5, 95, 180);
geometryGroup1.Children.Add(rectangleGeometry1);
geometryGroup1.Children.Add(rectangleGeometry2);

var ellipseGeometry1 = new EllipseGeometry();
ellipseGeometry1.Center = new Point(100, 100);
ellipseGeometry1.RadiusX = 20;
ellipseGeometry1.RadiusY = 30;
geometryGroup1.Children.Add(ellipseGeometry1);

var pathGeometry1 = new PathGeometry();
var pathFigureCollection1 = new PathFigureCollection();
var pathFigure1 = new PathFigure();
pathFigure1.IsClosed = true;
pathFigure1.StartPoint = new Windows.Foundation.Point(50, 50);
pathFigureCollection1.Add(pathFigure1);
pathGeometry1.Figures = pathFigureCollection1;
```

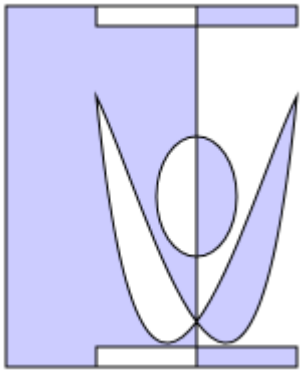
```
var pathSegmentCollection1 = new PathSegmentCollection();
var pathSegment1 = new BezierSegment();
pathSegment1.Point1 = new Point(75, 300);
pathSegment1.Point2 = new Point(125, 100);
pathSegment1.Point3 = new Point(150, 50);
pathSegmentCollection1.Add(pathSegment1);

var pathSegment2 = new BezierSegment();
pathSegment2.Point1 = new Point(125, 300);
pathSegment2.Point2 = new Point(75, 100);
pathSegment2.Point3 = new Point(50, 50);
pathSegmentCollection1.Add(pathSegment2);
pathFigure1.Segments = pathSegmentCollection1;

geometryGroup1.Children.Add(pathGeometry1);
path1.Data = geometryGroup1;

// When you create a XAML element in code, you have to add
// it to the XAML visual tree. This example assumes you have
// a panel named 'layoutRoot' in your XAML file, like this:
// <Grid x:Name="layoutRoot">
layoutRoot.Children.Add(path1);
```

Here's the rendered **Path**.



Using **PathGeometry** may be more readable than populating a **Path.Data** string. On the other hand, **Path.Data** uses a syntax compatible with Scalable Vector Graphics (SVG) image path definitions so it may be useful for porting graphics from SVG, or as output from a tool like Blend.

UWP and WinUI 2

> **ⓘ Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that

use **WinUI 2**. See the UWP API reference for platform specific information and examples.

This section contains information you need to use the control in a UWP or WinUI 2 app.

APIs for these shapes exist in the Windows.UI.Xaml.Shapes namespace.

- ✓ **UWP APIs:** Path class, Windows.UI.Xaml.Shapes namespace, Windows.UI.Xaml.Media namespace

Web view

Article • 03/16/2023

A web view control embeds a view into your app that renders web content using the Microsoft Edge Legacy rendering engine. Hyperlinks can also appear and function in a web view control.

> **ⓘ Important**
>
> The `WebView2` control is available as part of WinUI3. `WebView2` uses Microsoft Edge (Chromium) as the rendering engine to display web content in apps. For more info, see Introduction to Microsoft Edge WebView2, Getting started with WebView2 in WinUI 3 (Preview), and WebView2 in the WinUI API reference.

Is this the right control?

Use a web view control to display richly formatted HTML content from a remote web server, dynamically generated code, or content files in your app package. Rich content can also contain script code and communicate between the script and your app's code.

Recommendations

- Make sure that the website loaded is formatted correctly for the device and uses colors, typography, and navigation that are consistent with the rest of your app.
- Input fields should be appropriately sized. Users may not realize that they can zoom in to enter text.
- If a web view doesn't look like the rest of your app, consider alternative controls or ways to accomplish relevant tasks. If your web view matches the rest of your app, users will see it all as one seamless experience.

Create a web view

- ✓ **UWP APIs:** WebView class
- ✓ Open the WinUI 2 Gallery app and see the WebView in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

Modify the appearance of a web view

WebView is not a Control subclass, so it doesn't have a control template. However, you can set various properties to control some visual aspects of the web view.

- To constrain the display area, set the Width and Height properties.
- To translate, scale, skew, and rotate a web view, use the RenderTransform property.
- To control the opacity of the web view, set the Opacity property.
- To specify a color to use as the web page background when the HTML content does not specify a color, set the DefaultBackgroundColor property.

Get the web page title

You can get the title of the HTML document currently displayed in the web view by using the DocumentTitle property.

Input events and tab order

Although WebView is not a Control subclass, it will receive keyboard input focus and participate in the tab sequence. It provides a Focus method, and GotFocus and LostFocus events, but it has no tab-related properties. Its position in the tab sequence is the same as its position in the XAML document order. The tab sequence includes all elements in the web view content that can receive input focus.

As indicated in the Events table on the WebView class page, web view doesn't support most of the user input events inherited from UIElement, such as KeyDown, KeyUp, and PointerPressed. Instead, you can use InvokeScriptAsync with the JavaScript **eval** function to use the HTML event handlers, and to use **window.external.notify** from the HTML event handler to notify the application using WebView.ScriptNotify.

Navigating to content

Web view provides several APIs for basic navigation: GoBack, GoForward, Stop, Refresh, CanGoBack, and CanGoForward. You can use these to add typical web browsing capabilities to your app.

To set the initial content of the web view, set the Source property in XAML. The XAML parser automatically converts the string to a Uri.

XAML

```
<!-- Source file is on the web. -->
<WebView x:Name="webView1" Source="http://www.contoso.com"/>

<!-- Source file is in local storage. -->
```

```
<WebView x:Name="webView2" Source="ms-appdata:///local/intro/welcome.html"/>

<!-- Source file is in the app package. -->
<WebView x:Name="webView3" Source="ms-appx-web:///help/about.html"/>
```

The Source property can be set in code, but rather than doing so, you typically use one of the **Navigate** methods to load content in code.

To load web content, use the Navigate method with a **Uri** that uses the http or https scheme.

C#

```
webView1.Navigate(new Uri("http://www.contoso.com"));
```

To navigate to a URI with a POST request and HTTP headers, use the NavigateWithHttpRequestMessage method. This method supports only HttpMethod.Post and HttpMethod.Get for the HttpRequestMessage.Method property value.

To load uncompressed and unencrypted content from your app's LocalFolder or TemporaryFolder data stores, use the **Navigate** method with a **Uri** that uses the ms-appdata scheme. The web view support for this scheme requires you to place your content in a subfolder under the local or temporary folder. This enables navigation to URIs such as ms-appdata:///local/*folder*/*file*.html and ms-appdata:///temp/*folder*/*file*.html . (To load compressed or encrypted files, see NavigateToLocalStreamUri.)

Each of these first-level subfolders is isolated from the content in other first-level subfolders. For example, you can navigate to ms-appdata:///temp/folder1/file.html, but you can't have a link in this file to ms-appdata:///temp/folder2/file.html. However, you can still link to HTML content in the app package using the **ms-appx-web scheme**, and to web content using the **http** and **https** URI schemes.

C#

```
webView1.Navigate(new Uri("ms-appdata:///local/intro/welcome.html"));
```

To load content from the your app package, use the **Navigate** method with a **Uri** that uses the ms-appx-web scheme.

C#

```
webView1.Navigate(new Uri("ms-appx-web:///help/about.html"));
```

You can load local content through a custom resolver using the NavigateToLocalStreamUri method. This enables advanced scenarios such as downloading and caching web-based content for offline use, or extracting content from a compressed file.

Responding to navigation events

The web view control provides several events that you can use to respond to navigation and content loading states. The events occur in the following order for the root web view content: NavigationStarting, ContentLoading, DOMContentLoaded, NavigationCompleted

NavigationStarting - Occurs before the web view navigates to new content. You can cancel navigation in a handler for this event by setting the WebViewNavigationStartingEventArgs.Cancel property to true.

C#

```
webView1.NavigationStarting += webView1_NavigationStarting;

private void webView1_NavigationStarting(object sender,
WebViewNavigationStartingEventArgs args)
{
    // Cancel navigation if URL is not allowed. (Implementation of
IsAllowedUri not shown.)
    if (!IsAllowedUri(args.Uri))
        args.Cancel = true;
}
```

ContentLoading - Occurs when the web view has started loading new content.

C#

```
webView1.ContentLoading += webView1_ContentLoading;

private void webView1_ContentLoading(WebView sender,
WebViewContentLoadingEventArgs args)
{
    // Show status.
    if (args.Uri != null)
    {
        statusTextBlock.Text = "Loading content for " + args.Uri.ToString();
```

```
    }
}
```

DOMContentLoaded - Occurs when the web view has finished parsing the current HTML content.

C#

```
webView1.DOMContentLoaded += webView1_DOMContentLoaded;

private void webView1_DOMContentLoaded(WebView sender,
WebViewDOMContentLoadedEventArgs args)
{
    // Show status.
    if (args.Uri != null)
    {
        statusTextBlock.Text = "Content for " + args.Uri.ToString() + " has
finished loading";
    }
}
```

NavigationCompleted - Occurs when the web view has finished loading the current content or if navigation has failed. To determine whether navigation has failed, check the IsSuccess and WebErrorStatus properties of the WebViewNavigationCompletedEventArgs class.

C#

```
webView1.NavigationCompleted += webView1_NavigationCompleted;

private void webView1_NavigationCompleted(WebView sender,
WebViewNavigationCompletedEventArgs args)
{
    if (args.IsSuccess == true)
    {
        statusTextBlock.Text = "Navigation to " + args.Uri.ToString() + "
completed successfully.";
    }
    else
    {
        statusTextBlock.Text = "Navigation to: " + args.Uri.ToString() +
                               " failed with error " +
args.WebErrorStatus.ToString();
    }
}
```

Similar events occur in the same order for each **iframe** in the web view content:

- FrameNavigationStarting - Occurs before a frame in the web view navigates to new content.
- FrameContentLoading - Occurs when a frame in the web view has started loading new content.
- FrameDOMContentLoaded - Occurs when a frame in the web view has finished parsing its current HTML content.
- FrameNavigationCompleted - Occurs when a frame in the web view has finished loading its content.

Responding to potential problems

You can respond to potential problems with the content such as long running scripts, content that web view can't load, and warnings of unsafe content.

Your app might appear unresponsive while scripts are running. The LongRunningScriptDetected event occurs periodically while the web view executes JavaScript and provides an opportunity to interrupt the script. To determine how long the script has been running, check the ExecutionTime property of the WebViewLongRunningScriptDetectedEventArgs. To halt the script, set the event args StopPageScriptExecution property to **true**. The halted script will not execute again unless it is reloaded during a subsequent web view navigation.

The web view control cannot host arbitrary file types. When an attempt is made to load content that the web view can't host, the UnviewableContentIdentified event occurs. You can handle this event and notify the user, or use the Launcher class to redirect the file to an external browser or another app.

Similarly, the UnsupportedUriSchemeIdentified event occurs when a URI scheme that's not supported is invoked in the web content, such as fbconnect:// or mailto://. You can handle this event to provide custom behavior instead of allowing the default system launcher to launch the URI.

The UnsafeContentWarningDisplayingevent occurs when the web view shows a warning page for content that was reported as unsafe by the SmartScreen Filter. If the user chooses to continue the navigation, subsequent navigation to the page will not display the warning nor fire the event.

Handling special cases for web view content

You can use the ContainsFullScreenElement property and ContainsFullScreenElementChanged event to detect, respond to, and enable full-screen experiences in web content, such as full-screen video playback. For example, you may

use the ContainsFullScreenElementChanged event to resize the web view to occupy the entirety of your app view, or, as the following example illustrates, put a windowed app in full screen mode when a full screen web experience is desired.

C#

```
// Assume webView is defined in XAML
webView.ContainsFullScreenElementChanged +=
webView_ContainsFullScreenElementChanged;

private void webView_ContainsFullScreenElementChanged(WebView sender, object
args)
{
    var applicationView = ApplicationView.GetForCurrentView();

    if (sender.ContainsFullScreenElement)
    {
        applicationView.TryEnterFullScreenMode();
    }
    else if (applicationView.IsFullScreenMode)
    {
        applicationView.ExitFullScreenMode();
    }
}
```

You can use the NewWindowRequested event to handle cases where hosted web content requests a new window to be displayed, such as a popup window. You can use another WebView control to display the contents of the requested window.

Use PermissionRequested event to enable web features that require special capabilities. These currently include geolocation, IndexedDB storage, and user audio and video (for example, from a microphone or webcam). If your app accesses user location or user media, you still are required to declare this capability in the app manifest. For example, an app that uses geolocation needs the following capability declarations at minimum in Package.appxmanifest:

XML

```
  <Capabilities>
    <Capability Name="internetClient" />
    <DeviceCapability Name="location" />
  </Capabilities>
```

In addition to the app handling the PermissionRequested event, the user will have to approve standard system dialogs for apps requesting location or media capabilities in order for these features to be enabled.

Here is an example of how an app would enable geolocation in a map from Bing:

```
C#
```

```
// Assume webView is defined in XAML
webView.PermissionRequested += webView_PermissionRequested;

private void webView_PermissionRequested(WebView sender,
WebViewPermissionRequestedEventArgs args)
{
    if (args.PermissionRequest.PermissionType ==
WebViewPermissionType.Geolocation &&
        args.PermissionRequest.Uri.Host == "www.bing.com")
    {
        args.PermissionRequest.Allow();
    }
}
```

If your app requires user input or other asynchronous operations to respond to a permission request, use the Defer method of WebViewPermissionRequest to create a WebViewDeferredPermissionRequest that can be acted upon at a later time. See WebViewPermissionRequest.Defer.

If users must securely log out of a website hosted in a web view, or in other cases when security is important, call the static method ClearTemporaryWebDataAsync to clear out all locally cached content from a web view session. This prevents malicious users from accessing sensitive data.

Interacting with web view content

You can interact with the content of the web view by using the InvokeScriptAsync method to invoke or inject script into the web view content, and the ScriptNotify event to get information back from the web view content.

To invoke JavaScript inside the web view content, use the InvokeScriptAsync method. The invoked script can return only string values.

For example, if the content of a web view named `webView1` contains a function named `setDate` that takes 3 parameters, you can invoke it like this.

```
C#
```

```
string[] args = {"January", "1", "2000"};
string returnValue = await webView1.InvokeScriptAsync("setDate", args);
```

You can use **InvokeScriptAsync** with the JavaScript **eval** function to inject content into the web page.

Here, the text of a XAML text box (`nameTextBox.Text`) is written to a div in an HTML page hosted in `webView1`.

C#

```
private async void Button_Click(object sender, RoutedEventArgs e)
{
    string functionString =
String.Format("document.getElementById('nameDiv').innerText = 'Hello,
{0}';", nameTextBox.Text);
    await webView1.InvokeScriptAsync("eval", new string[] { functionString
});
}
```

Scripts in the web view content can use **window.external.notify** with a string parameter to send information back to your app. To receive these messages, handle the ScriptNotify event.

To enable an external web page to fire the **ScriptNotify** event when calling window.external.notify, you must include the page's URI in the **ApplicationContentUriRules** section of the app manifest. (You can do this in Microsoft Visual Studio on the Content URIs tab of the Package.appxmanifest designer.) The URIs in this list must use HTTPS, and may contain subdomain wildcards (for example, `https://*.microsoft.com`) but they cannot contain domain wildcards (for example, `https://*.com` and `https://*.*`). The manifest requirement does not apply to content that originates from the app package, uses an ms-local-stream:// URI, or is loaded using NavigateToString.

Accessing the Windows Runtime in a web view

You can use the AddWebAllowedObject method to inject an instance of a native class from a Windows Runtime component into the JavaScript context of the web view. This allows full access to the native methods, properties, and events of that object in the JavaScript content of that web view. The class must be decorated with the AllowForWeb attribute.

For example, this code injects an instance of `MyClass` imported from a Windows Runtime component into a web view.

C#

```
private void webView_NavigationStarting(WebView sender,
WebViewNavigationStartingEventArgs args)
{
    if (args.Uri.Host == "www.contoso.com")
    {
        webView.AddWebAllowedObject("nativeObject", new MyClass());
    }
}
```

For more info, see WebView.AddWebAllowedObject.

In addition, trusted JavaScript content in a web view can be allowed to directly access Windows Runtime APIs. This provides powerful native capabilities for web apps hosted in a web view. To enable this feature, the URI for trusted content must be allowlisted in the ApplicationContentUriRules of the app in Package.appxmanifest, with WindowsRuntimeAccess specifically set to "all".

This example shows a section of the app manifest. Here, a local URI is given access to the Windows Runtime.

XML

```
  <Applications>
    <Application Id="App"
      ...

      <uap:ApplicationContentUriRules>
        <uap:Rule Match="ms-appx-web:///Web/App.html"
WindowsRuntimeAccess="all" Type="include"/>
      </uap:ApplicationContentUriRules>
    </Application>
  </Applications>
```

Options for web content hosting

You can use the WebView.Settings property (of type WebViewSettings) to control whether JavaScript and IndexedDB are enabled. For example, if you use a web view to display strictly static content, you might want to disable JavaScript for best performance.

Capturing web view content

To enable sharing web view content with other apps, use the CaptureSelectedContentToDataPackageAsync method, which returns the selected content as a DataPackage. This method is asynchronous, so you must use a deferral to

prevent your DataRequested event handler from returning before the asynchronous call is complete.

To get a preview image of the web view's current content, use the CapturePreviewToStreamAsync method. This method creates an image of the current content and writes it to the specified stream.

Threading behavior

By default, web view content is hosted on the UI thread on devices in the desktop device family, and off the UI thread on all other devices. You can use the WebView.DefaultExecutionMode static property to query the default threading behavior for the current client. If necessary, you can use the WebView(WebViewExecutionMode) constructor to override this behavior.

> **Note** There might be performance issues when hosting content on the UI thread on mobile devices, so be sure to test on all target devices when you change DefaultExecutionMode.

A web view that hosts content off the UI thread is not compatible with parent controls that require gestures to propagate up from the web view control to the parent, such as FlipView, ScrollViewer, and other related controls. These controls will not be able to receive gestures initiated in the off-thread web view. In addition, printing off-thread web content is not directly supported – you should print an element with WebViewBrush fill instead.

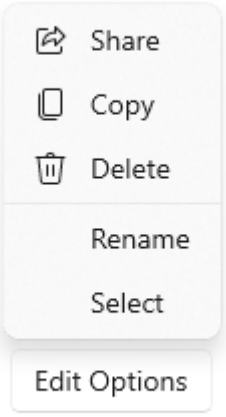
Menus and context menus

Article • 10/24/2022

Menus and context menus are similar in how they look and what they can contain. They both display an organized list of commands or options and save space by hiding until the user needs them. However there are differences between them, such as what you should use to create them and how they are accessed by a user.



Is this the right control?

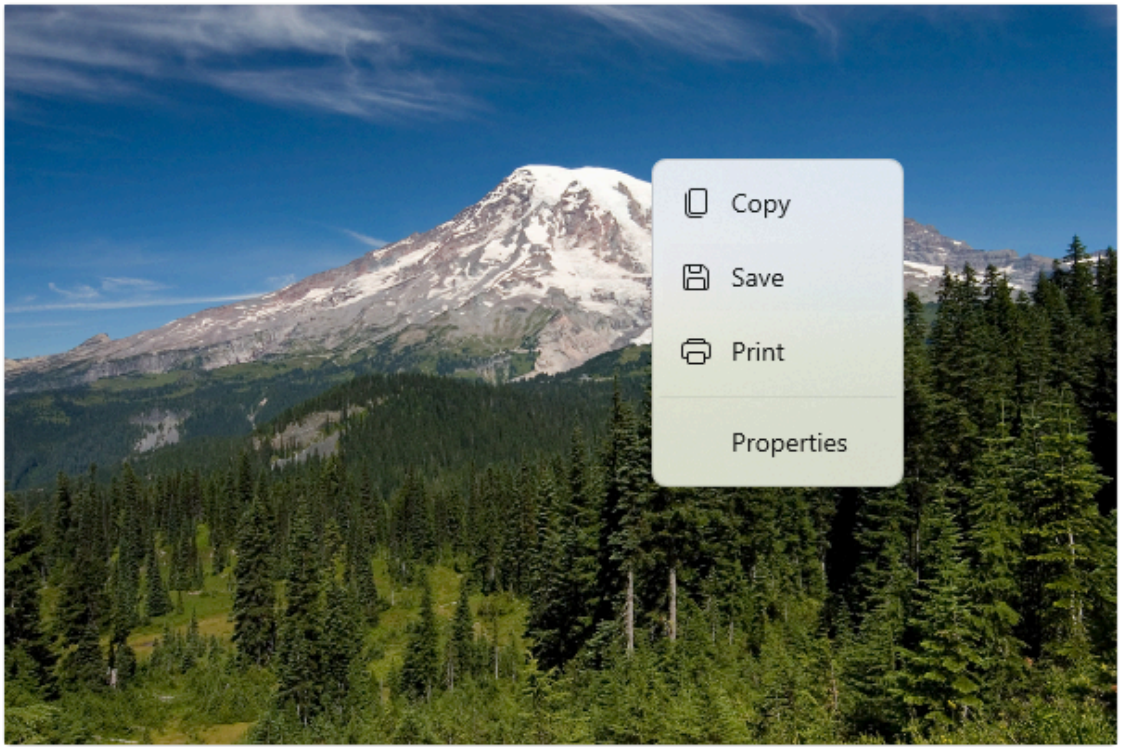
Menus and context menus are for organizing commands and saving space by hiding those commands until the user needs them. To display arbitrary content, such as a notification or confirmation request, use a dialog or a flyout.

If a particular command will be used frequently and you have the space available, consider placing it directly in its own element so that users don't have to go through a menu to get to it.

When should you use a menu or a context menu?

- If the host element is a button or some other command element whose primary role is to present additional commands, use a menu.
- If the host element is some other type of element that has another primary purpose (such as presenting text or an image), use a context menu.

If you want to add commands (such as Cut, Copy, and Paste) to a text or image element, use a context menu instead of a menu. In this scenario, the primary role of the text element is to present and edit text; additional commands (such as Cut, Copy, and Paste) are secondary and belong in a context menu.



Context menus

Context menus have the following characteristics:

- Are attached to a single element and display secondary commands.
- Are invoked by right clicking (or an equivalent action, such as pressing and holding with your finger).
- Are associated with an element via its ContextFlyout property.

In cases where your context menu will include common commands (such as Copy, Cut, Paste, Delete, Share, or text selection commands), use command bar flyout and group these common commands together as primary commands so that they will be shown as a single, horizontal row in the context menu.

In cases where your context menu will not include common commands, either command bar flyout or menu flyout can be used to show a context menu. We recommend using CommandBarFlyout because it provides more functionality than MenuFlyout and, if desired, can achieve the same behavior and look of MenuFlyout by using only secondary commands.

Menus

Menus have the following characteristics:

- Have a single entry point (a File menu at the top of the screen, for example) that is always displayed.
- Are usually attached to a button or a parent menu item.
- Are invoked by left-clicking (or an equivalent action, such as tapping with your finger).
- Are associated with an element via its Flyout or FlyoutBase.AttachedFlyout properties, or grouped in a menu bar at the top of the app window.

When the user invokes a command element (such as a button) whose primary role is to present additional commands, use menu flyout to host a single top-level menu to be shown inline as a flyout attached to the on-canvas UI element. Each MenuFlyout can host menu items and sub-menus. For apps that might need more organization or grouping, use a menu bar as a quick and simple way to show a set of multiple top-level menus in a horizontal row.

UWP and WinUI 2

> **Important**
>
> The information and examples in this article are optimized for apps that use the **Windows App SDK** and **WinUI 3**, but are generally applicable to UWP apps that use **WinUI 2**. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

The CommandBarFlyout and MenuBar controls for UWP apps are included as part of WinUI 2. For more info, including installation instructions, see WinUI 2. APIs for these controls exist in both the Windows.UI.Xaml.Controls and Microsoft.UI.Xaml.Controls namespaces.

- ✓ **UWP APIs:** AppBarButton class, AppBarSeparator class, AppBarToggleButton class, CommandBarFlyout class, ContextFlyout property, FlyoutBase.AttachedFlyout property, MenuBar class, MenuFlyout class, TextCommandBarFlyout class
- ✓ **WinUI 2 Apis:** CommandBarFlyout class, MenuBar class, TextCommandBarFlyout class

- ✔ Open the WinUI 2 Gallery app and see the MenuBar or CommandBarFlyout in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles and templates for all controls. WinUI 2.2 or later includes a new template for these controls that uses rounded corners. For more info, see Corner radius.

To use the code in this article with WinUI 2, use an alias in XAML (we use `muxc`) to represent the Windows UI Library APIs that are included in your project. See Get Started with WinUI 2 for more info.

XAML

```
xmlns:muxc="using:Microsoft.UI.Xaml.Controls"

<muxc:CommandBarFlyout />
<muxc:MenuBar />
```

Command bar

Article • 02/26/2025

Command bars provide users with easy access to your app's most common tasks. Command bars can provide access to app-level or page-specific commands and can be used with any navigation pattern.

Is this the right control?

The CommandBar control is a general-purpose, flexible, light-weight control that can display both complex content, such as images or text blocks, as well as simple commands such as AppBarButton, AppBarToggleButton, and AppBarSeparator controls.

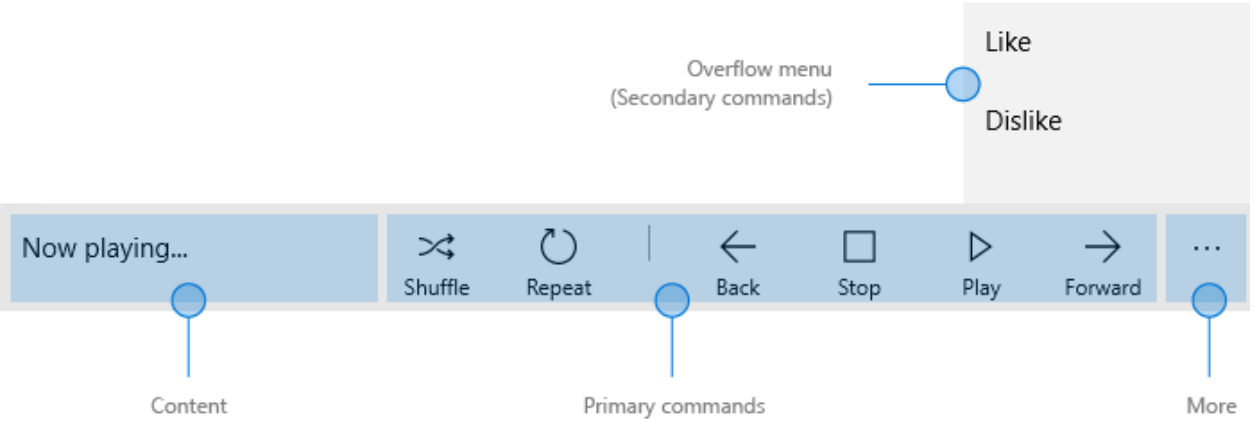
> **Note**
>
> XAML provides both the **AppBar** control and the **CommandBar** control. You should use the AppBar only when you are upgrading a Universal Windows 8 app that uses the AppBar, and need to minimize changes. For new apps in Windows 10, we recommend using the CommandBar control instead. This document assumes you are using the CommandBar control.

Anatomy

By default, the command bar shows a row of icon buttons and an optional "see more" button, which is represented by an ellipsis [...]. Here's the command bar created by the example code shown later. It's shown in its closed compact state.

The command bar can also be shown in a closed minimal state that looks like this. See the Open and closed states section for more info.

Here's the same command bar in its open state. The labels identify the main parts of the control.



The command bar is divided into 4 main areas:

- The content area is aligned to the left side of the bar. It is shown if the Content property is populated.
- The primary command area is aligned to the right side of the bar. It is shown if the PrimaryCommands property is populated.
- The "see more" [...] button is shown on the right of the bar. Pressing the "see more" [...] button reveals primary command labels and opens the overflow menu if there are secondary commands. The button will not be visible when no primary command labels or secondary labels are present. To change default behavior, use the OverflowButtonVisibility property.
- The overflow menu is shown only when the command bar is open and the SecondaryCommands property is populated. When space is limited, primary commands will move into the SecondaryCommands area. To change default behavior, use the IsDynamicOverflowEnabled property.

The layout is reversed when the FlowDirection is **RightToLeft**.

Placement

Command bars can be placed at the top of the app window, at the bottom of the app window, and inline, by embedding them in a layout control such as `Grid.row`.

- For small handheld devices, we recommend positioning command bars at the bottom of the screen for easy reachability.
- For devices with larger screens, placing command bars near the top of the window makes them more noticeable and discoverable.

Use the DiagonalSizeInInches API to determine physical screen size.

Command bars can be placed in the following screen regions on single-view screens (left example) and on multi-view screens (right example). Inline command bars can be placed anywhere in the action space.

> **Touch devices**: If the command bar must remain visible to a user when the touch keyboard, or Soft Input Panel (SIP), appears then you can assign the command bar to the BottomAppBar property of a Page and it will move to remain visible when the SIP is present. Otherwise, you should place the command bar inline and positioned relative to your app content.

Create a command bar

✓ **Important APIs:** CommandBar class, AppBarButton class, AppBarToggleButton class, AppBarSeparator class

Open the WinUI 3 Gallery app and see the CommandBar in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

This example creates the command bar shown previously.

XAML

```
<CommandBar>
    <AppBarToggleButton Icon="Shuffle" Label="Shuffle"
Click="AppBarButton_Click" />
    <AppBarToggleButton Icon="RepeatAll" Label="Repeat"
Click="AppBarButton_Click"/>
    <AppBarSeparator/>
    <AppBarButton Icon="Back" Label="Back" Click="AppBarButton_Click"/>
    <AppBarButton Icon="Stop" Label="Stop" Click="AppBarButton_Click"/>
    <AppBarButton Icon="Play" Label="Play" Click="AppBarButton_Click"/>
    <AppBarButton Icon="Forward" Label="Forward"
Click="AppBarButton_Click"/>

    <CommandBar.SecondaryCommands>
        <AppBarButton Label="Like" Click="AppBarButton_Click"/>
        <AppBarButton Label="Dislike" Click="AppBarButton_Click"/>
    </CommandBar.SecondaryCommands>

    <CommandBar.Content>
        <TextBlock Text="Now playing..." Margin="12,14"/>
    </CommandBar.Content>
</CommandBar>
```

Commands and content

The CommandBar control has 3 properties you can use to add commands and content: PrimaryCommands, SecondaryCommands, and Content.

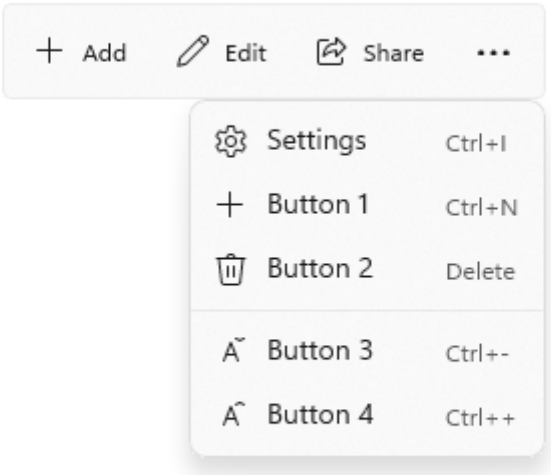
Commands

By default, command bar items are added to the **PrimaryCommands** collection. You should add commands in order of their importance so that the most important commands are always visible. When the command bar width changes, such as when

users resize their app window, primary commands dynamically move between the command bar and the overflow menu at breakpoints. To change this default behavior, use the IsDynamicOverflowEnabled property.

On the smallest screens (320 epx width), a maximum of 4 primary commands fit in the command bar.

You can also add commands to the **SecondaryCommands** collection, which are shown in the overflow menu.



You can programmatically move commands between the PrimaryCommands and SecondaryCommands as needed.

- *If there is a command that would appear consistently across pages, it's best to keep that command in a consistent location.*
- *We recommended placing Accept, Yes, and OK commands to the left of Reject, No, and Cancel. Consistency gives users the confidence to move around the system and helps them transfer their knowledge of app navigation from app to app.*

App bar buttons

Both the PrimaryCommands and SecondaryCommands can be populated only with types that implement the ICommandBarElement interface, which includes AppBarButton, AppBarToggleButton, and AppBarSeparator command elements.

If you'd like to include a different type of element in your PrimaryCommands or SecondaryCommands, you can use the AppBarElementContainer class. This will serve as a wrapper for your element and will enable the element to display in a CommandBar.

The app bar button controls are characterized by an icon and text label. These controls are optimized for use in a command bar, and their appearance changes depending on whether the control is used in the command bar or the overflow menu.

Icons

The size of the icons when shown in the primary command area is 20x20px; in the overflow menu, icons are displayed at 16x16px. If you use SymbolIcon, FontIcon, or PathIcon, the icon will automatically scale to the correct size with no loss of fidelity when the command enters the secondary command area.

For more information and examples of setting the icon, see the documentation for the AppBarButton class.

Labels

The AppBarButton IsCompact property determines whether the label is shown. In a CommandBar control, the command bar overwrites the button's IsCompact property automatically as the command bar is opened and closed.

To position app bar button labels, use CommandBar's DefaultLabelPosition property.

XAML

```
<CommandBar DefaultLabelPosition="Right">
    <AppBarToggleButton Icon="Edit" Label="Edit"/>
    <AppBarToggleButton Icon="Share" Label="Share"/>
</CommandBar>
```

On larger windows, consider moving labels to the right of app bar button icons to improve legibility. Labels on the bottom require users to open the command bar to reveal labels, while labels on the right are visible even when command bar is closed.

In overflow menus, labels are positioned to the right of icons by default, and **LabelPosition** is ignored. You can adjust the styling by setting the CommandBarOverflowPresenterStyle property to a Style that targets the CommandBarOverflowPresenter.

Button labels should be short, preferably a single word. Longer labels below an icon will wrap to multiple lines, increasing the overall height of the opened command bar. You

can include a soft-hyphen character (0x00AD) in the text for a label to hint at the character boundary where a word break should occur. In XAML, you express this using an escape sequence, like this:

XAML

```
<AppBarButton Icon="Back" Label="Areally&#x00AD;longlabel"/>
```

When the label wraps at the hinted location, it looks like this.

SplitButton

You can display a SplitButton in a CommandBar using the built-in `SplitButtonCommandBarStyle` and the AppBarElementContainer class. `SplitButtonCommandBarStyle` provides visuals for a SplitButton to look and feel like an AppBarButton, while `AppBarElementContainer` is a wrapper class that provides the functionality that SplitButton needs to act like an AppBarButton.

When you wrap a SplitButton in an `AppBarElementContainer` and place it in a CommandBar, the `SplitButtonCommandBarStyle` resource is applied automatically.

This sample code creates and displays a SplitButton inside of a CommandBar:

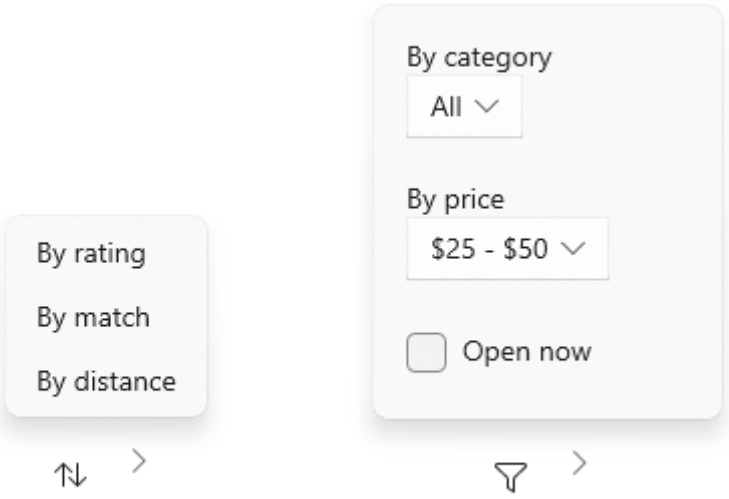
XAML

```
<CommandBar>
    <AppBarButton Icon="Copy" ToolTipService.ToolTip="Copy" Label="Copy"/>
    <AppBarElementContainer>
        <muxc:SplitButton ToolTipService.ToolTip="Insert" Content="Insert">
            <muxc:SplitButton.Flyout>
                <MenuFlyout Placement="RightEdgeAlignedTop">
                    <MenuFlyoutItem Text="Insert above"/>
                    <MenuFlyoutItem Text="Insert between"/>
                    <MenuFlyoutItem  Text="Insert below"/>
                </MenuFlyout>
            </muxc:SplitButton.Flyout>
        </muxc:SplitButton>
    </AppBarElementContainer>
```

```
    <AppBarButton Label="Select all"/>
    <AppBarButton Label="Delete" Icon="Delete"/>
</CommandBar>
```

Menus and flyouts

Consider logical groupings for the commands, such as placing Reply, Reply All, and Forward in a Respond menu. While typically an app bar button activates a single command, an app bar button can be used to show a MenuFlyout or Flyout with custom content.



Other content

You can add any XAML elements to the content area by setting the **Content** property. If you want to add more than one element, you need to place them in a panel container and make the panel the single child of the Content property.

When dynamic overflow is enabled, content will not clip because primary commands can move into the overflow menu. Otherwise, primary commands take precedence and may cause the content to be clipped.

When the ClosedDisplayMode is **Compact**, the content can be clipped if it is larger than the compact size of the command bar. You should handle the Opening and Closed events to show or hide parts of the UI in the content area so that they aren't clipped. See the Open and closed states section for more info.

Open and closed states

The command bar can be open or closed. When it's open, it shows primary command buttons with text labels and it opens the overflow menu (if there are secondary commands). The command bar opens the overflow menu upwards (above the primary commands) or downwards (below the primary commands). The default direction is up, but if there's not enough space to open the overflow menu upwards, the command bar opens it downwards.

A user can switch between these states by pressing the "see more" [...] button. You can switch between them programmatically by setting the IsOpen property.

You can use the Opening, Opened, Closing, and Closed events to respond to the command bar being opened or closed.

- The Opening and Closing events occur before the transition animation begins.
- The Opened and Closed events occur after the transition completes.

In this example, the Opening and Closing events are used to change the opacity of the command bar. When the command bar is closed, it's semi-transparent so the app background shows through. When the command bar is opened, the command bar is made opaque so the user can focus on the commands.

XAML

```
<CommandBar Opening="CommandBar_Opening"
            Closing="CommandBar_Closing">
    <AppBarButton Icon="Accept" Label="Accept"/>
    <AppBarButton Icon="Edit" Label="Edit"/>
    <AppBarButton Icon="Save" Label="Save"/>
    <AppBarButton Icon="Cancel" Label="Cancel"/>
</CommandBar>
```

C#

```
private void CommandBar_Opening(object sender, object e)
{
    CommandBar cb = sender as CommandBar;
    if (cb != null) cb.Background.Opacity = 1.0;
}

private void CommandBar_Closing(object sender, object e)
{
    CommandBar cb = sender as CommandBar;
    if (cb != null) cb.Background.Opacity = 0.5;
}
```

IsSticky

If a user interacts with other parts of an app when a command bar is open, then the command bar will automatically close. This is called *light dismiss*. You can control light dismiss behavior by setting the IsSticky property. When `IsSticky="true"`, the bar remains open until the user presses the "see more" [...] button or selects an item from the overflow menu.

We recommend avoiding sticky command bars because they don't conform to users' expectations for light dismiss and keyboard focus behavior.

Display Mode

You can control how the command bar is shown in its closed state by setting the ClosedDisplayMode property. There are 3 closed display modes to choose from:

- **Compact**: The default mode. Shows content, primary command icons without labels, and the "see more" [...] button.
- **Minimal**: Shows only a thin bar that acts as the "see more" [...] button. The user can press anywhere on the bar to open it.
- **Hidden**: The command bar is not shown when it's closed. This can be useful for showing contextual commands with an inline command bar. In this case, you must open the command bar programmatically by setting the **IsOpen** property or changing the ClosedDisplayMode to **Minimal** or **Compact**.

Here, a command bar is used to hold simple formatting commands for a RichEditBox. When the edit box doesn't have focus, the formatting commands can be distracting, so they're hidden. When the edit box is being used, the command bar's ClosedDisplayMode is changed to Compact so the formatting commands are visible.

XAML

```
<StackPanel Width="300"
            GotFocus="EditStackPanel_GotFocus"
            LostFocus="EditStackPanel_LostFocus">
    <CommandBar x:Name="FormattingCommandBar" ClosedDisplayMode="Hidden">
        <AppBarButton Icon="Bold" Label="Bold"
ToolTipService.ToolTip="Bold"/>
        <AppBarButton Icon="Italic" Label="Italic"
ToolTipService.ToolTip="Italic"/>
        <AppBarButton Icon="Underline" Label="Underline"
ToolTipService.ToolTip="Underline"/>
    </CommandBar>
    <RichEditBox Height="200"/>
</StackPanel>
```

C#

```
private void EditStackPanel_GotFocus(object sender, RoutedEventArgs e)
{
    FormattingCommandBar.ClosedDisplayMode =
AppBarClosedDisplayMode.Compact;
}

private void EditStackPanel_LostFocus(object sender, RoutedEventArgs e)
{
    FormattingCommandBar.ClosedDisplayMode = AppBarClosedDisplayMode.Hidden;
}
```

> **Note**
>
> The implementation of the editing commands is beyond the scope of this example. For more info, see the RichEditBox article.

Although the Minimal and Hidden modes are useful in some situations, keep in mind that hiding all actions could confuse users.

Changing the ClosedDisplayMode to provide more or less of a hint to the user affects the layout of surrounding elements. In contrast, when the CommandBar transitions between closed and open, it does not affect the layout of other elements.

UWP and WinUI 2

> **Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

APIs for this control exist in the Windows.UI.Xaml.Controls namespace.

- **UWP APIs:** CommandBar class, AppBarButton class, AppBarToggleButton class, AppBarSeparator class

- ✓ Open the WinUI 2 Gallery app and see the CommandBar in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles and templates for all controls. WinUI 2.2 or later includes a new template for this control that uses rounded corners. For more info, see Corner radius.

Automatic styling of a SplitButton in a CommandBar requires that you use the SplitButton control from WinUI 2.6 or later.

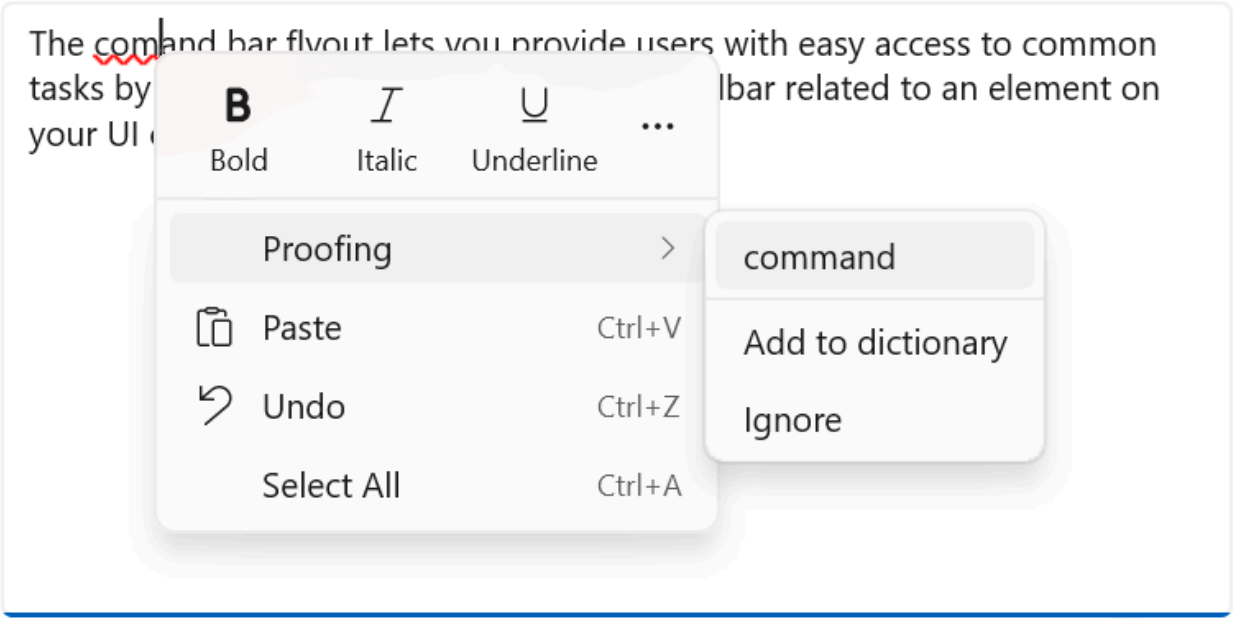
Command bar flyout

Article • 02/26/2025

The command bar flyout lets you provide users with easy access to common tasks by showing commands in a floating toolbar related to an element on your UI canvas.



Like CommandBar, CommandBarFlyout has **PrimaryCommands** and **SecondaryCommands** properties you can use to add commands. You can place commands in either collection, or both. When and how the primary and secondary commands are displayed depends on the display mode.

The command bar flyout has two display modes: *collapsed* and *expanded*.

- In the collapsed mode, only the primary commands are shown. If your command bar flyout has both primary and secondary commands, a "see more" button, which is represented by an ellipsis [...], is displayed. This lets the user get access to the secondary commands by transitioning to expanded mode.
- In the expanded mode, both the primary and secondary commands are shown. (If the control has only secondary items, they are shown in a way similar to the MenuFlyout control.)

Is this the right control?

Use the command bar flyout control to show a collection of commands to the user, such as buttons and menu items, in the context of an element on the app canvas.

Command bar flyout is the recommended control for creating context menus. This allows the common commands (such as Copy, Cut, Paste, Delete, Share or text selection commands) that are most contextually relevant for the context menu's scenario to be added as primary commands so that they will be shown as a single, horizontal row in the command bar flyout. The TextCommandBarFlyout is already configured appropriately to automatically display text commands in TextBox, TextBlock, RichEditBox, RichTextBlock, and PasswordBox controls. A CommandBarFlyout can be used to replace the default text commands on text controls.

To show contextual commands on list items follow the guidance in Contextual commanding for collections and lists.

Proactive vs. reactive invocation

There are typically two ways to invoke a flyout or menu that's associated with an element on your UI canvas: *proactive invocation* and *reactive invocation*.

In proactive invocation, commands appear automatically when the user interacts with the item that the commands are associated with. For example, text formatting commands might pop up when the user selects text in a text box. In this case, the command bar flyout does not take focus. Instead, it presents relevant commands close to the item the user is interacting with. If the user doesn't interact with the commands, they are dismissed.

In reactive invocation, commands are shown in response to an explicit user action to request the commands; for example, a right-click. This corresponds to the traditional concept of a context menu.

You can use the CommandBarFlyout in either way, or even a mixture of the two.

Create a command bar flyout

✓ **Important APIs:** CommandBarFlyout class, TextCommandBarFlyout class, AppBarButton class, AppBarToggleButton class, AppBarSeparator class

Open the WinUI 3 Gallery app and see the CommandBarFlyout in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

This example shows how to create a command bar flyout and use it both proactively and reactively. When the image is tapped, the flyout is shown in its collapsed mode. When shown as a context menu, the flyout is shown in its expanded mode. In either case, the user can expand or collapse the flyout after it's opened.

XAML

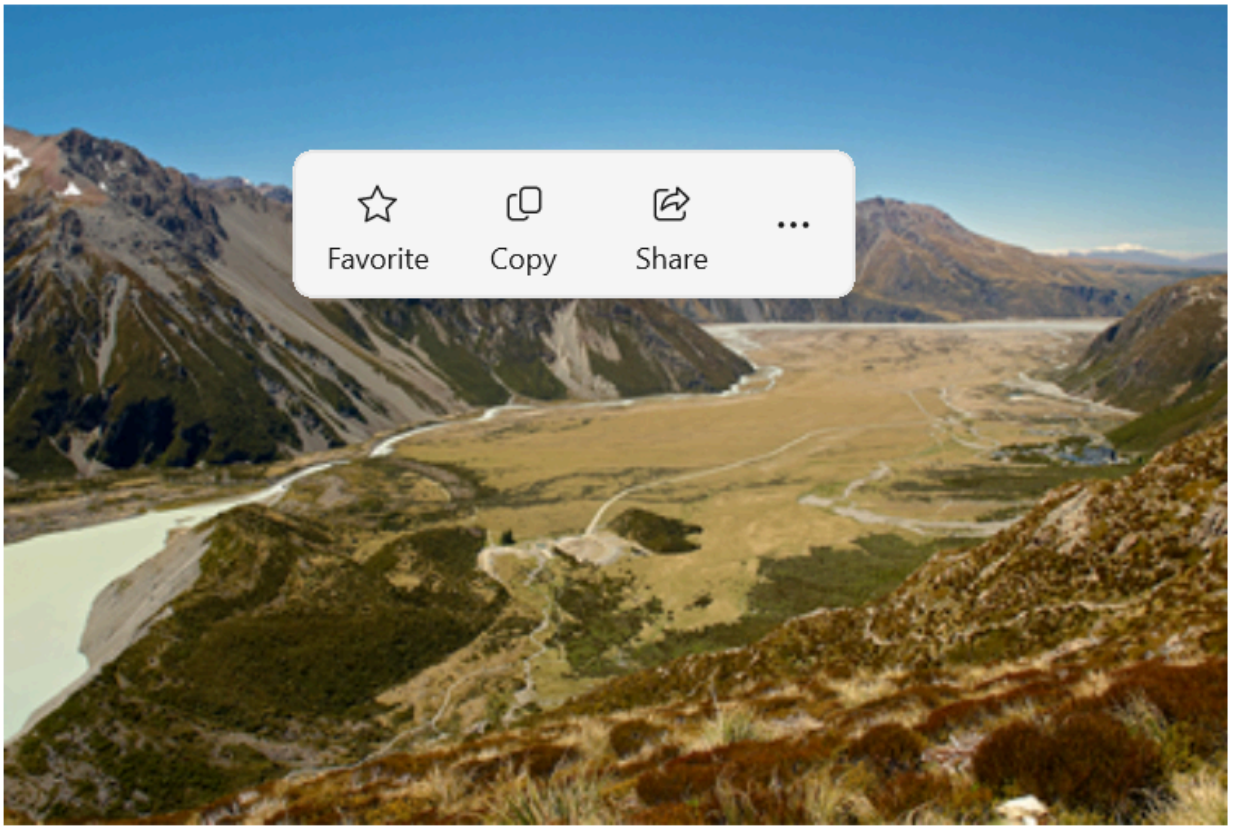
```
<Grid>
    <Grid.Resources>
        <CommandBarFlyout x:Name="ImageCommandsFlyout">
            <AppBarButton Label="Favorite" Icon="OutlineStar"
ToolTipService.ToolTip="Favorite"/>
            <AppBarButton Label="Copy" Icon="Copy"
ToolTipService.ToolTip="Copy"/>
            <AppBarButton Label="Share" Icon="Share"
ToolTipService.ToolTip="Share"/>
            <CommandBarFlyout.SecondaryCommands>
                <AppBarButton Label="Rotate" Icon="Rotate"/>
                <AppBarButton Label="Delete" Icon="Delete"/>
            </CommandBarFlyout.SecondaryCommands>
        </CommandBarFlyout>
    </Grid.Resources>

    <Image Source="Assets/image1.png" Width="300"
           Tapped="Image_Tapped"
           FlyoutBase.AttachedFlyout="{x:Bind ImageCommandsFlyout}"
           ContextFlyout="{x:Bind ImageCommandsFlyout}"/>
</Grid>
```

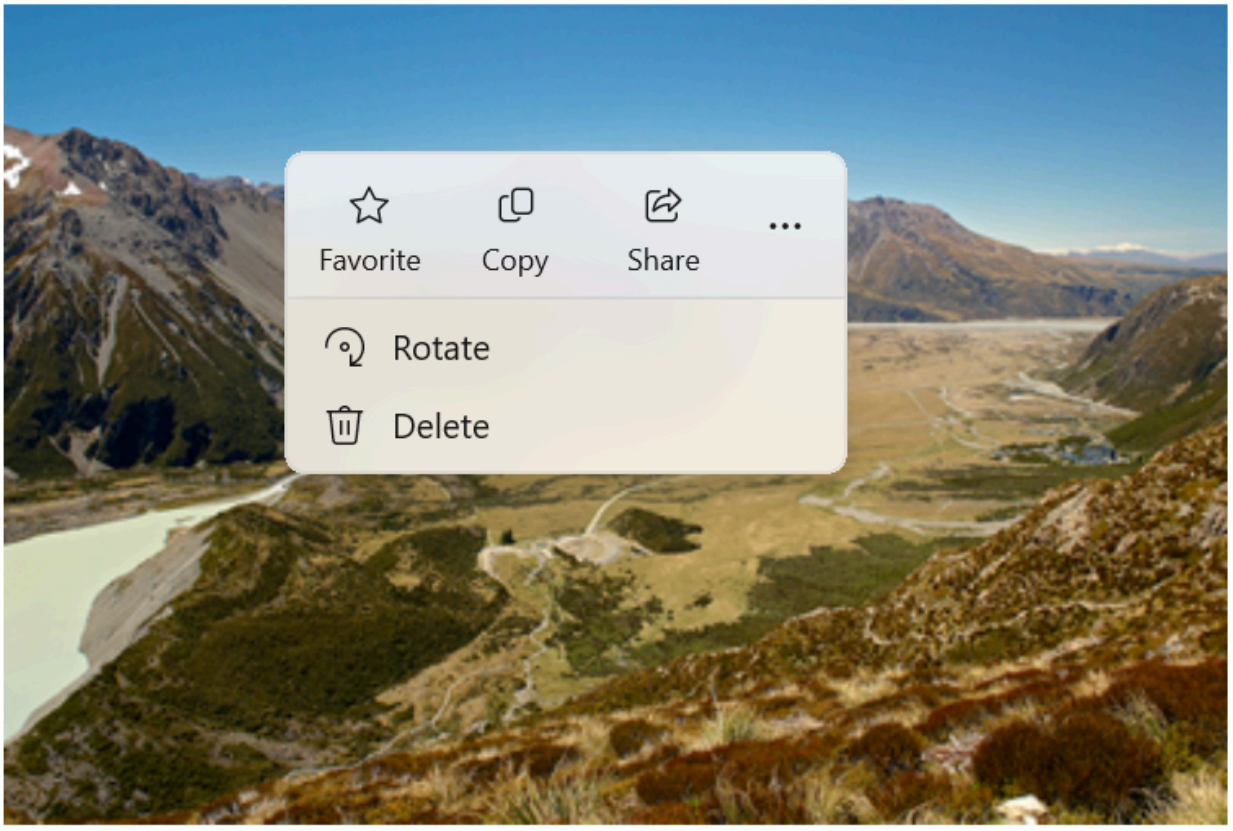
C#

```
private void Image_Tapped(object sender, TappedRoutedEventArgs e)
{
    var flyout = FlyoutBase.GetAttachedFlyout((FrameworkElement)sender);
    var options = new FlyoutShowOptions()
    {
        // Position shows the flyout next to the pointer.
        // "Transient" ShowMode makes the flyout open in its collapsed
state.
        Position = e.GetPosition((FrameworkElement)sender),
        ShowMode = FlyoutShowMode.Transient
    };
    flyout?.ShowAt((FrameworkElement)sender, options);
}
```

Here's the command bar flyout in its collapsed state.



Here's the same command bar flyout in its expanded state showing secondary commands.



Show commands proactively

When you show contextual commands proactively, only the primary commands should be shown by default (the command bar flyout should be collapsed). Place the most important commands in the primary commands collection, and additional commands that would traditionally go in a context menu into the secondary commands collection.

To proactively show commands, you typically handle the Click or Tapped event to show the command bar flyout. Set the flyout's ShowMode to **Transient** or **TransientWithDismissOnPointerMoveAway** to open the flyout in its collapsed mode without taking focus.

Text controls have a **SelectionFlyout** property. When you assign a flyout to this property, it is automatically shown when text is selected.

Show commands reactively

When you show contextual commands reactively, as a context menu, the secondary commands are shown by default (the command bar flyout should be expanded). In this case, the command bar flyout might have both primary and secondary commands, or secondary commands only.

To show commands in a context menu, you typically assign the flyout to the ContextFlyout property of a UI element. This way, opening the flyout is handled by the element, and you don't need to do anything more.

If you handle showing the flyout yourself (for example, on a RightTapped event), set the flyout's ShowMode to **Standard** to open the flyout in its expanded mode and give it focus.

> **Tip**
>
> For more info about options when showing a flyout and how to control placement of the flyout, see **Flyouts**.

Show an always expanded CommandBarFlyout

When you have primary and secondary commands in a CommandBarFlyout, the "see more" [...] button is displayed by default, and can be used to expand and collapse the secondary commands. If you'd like to keep your CommandBarFlyout in expanded mode and show the secondary commands at all times, you can use the `CommandBarFlyout.AlwaysExpanded` property.

When the `AlwaysExpanded` property is set to `true`, the "see more" button is not shown, and the user is not able to toggle the expanded state of the control. The CommandBarFlyout will still dismiss as usual when a secondary command is clicked or the user clicks outside of the flyout.

This property only has an effect if the CommandBarFlyout has secondary commands. If there are no secondary commands, the CommandBarFlyout will always be in collapsed mode.

> **Tip**
>
> You can still collapse and expand the CommandBarFlyout programmatically by setting the **IsOpen** property even when the `AlwaysExpanded` property is set to `true`.

Commands and content

The CommandBarFlyout control has 2 properties you can use to add commands and content: PrimaryCommands and SecondaryCommands.

By default, command bar items are added to the **PrimaryCommands** collection. These commands are shown in the command bar and are visible in both the collapsed and expanded modes. Unlike CommandBar, primary commands do not automatically overflow to the secondary commands and might be truncated.

You can also add commands to the **SecondaryCommands** collection. Secondary commands are shown in the menu portion of the control and are visible only in the expanded mode.

If there are **common commands** (such as Copy, Cut, Paste, Delete, Share or text selection commands) that are important to the scenario, it is recommended to add them as primary commands rather than secondary commands.

App bar buttons

You can populate the PrimaryCommands and SecondaryCommands directly with AppBarButton, AppBarToggleButton, and AppBarSeparator controls.

The app bar button controls are characterized by an icon and text label. These controls are optimized for use in a command bar, and their appearance changes depending on whether the control is shown in the command bar or the overflow menu.

- **In Windows App SDK 1.5 and later:** App bar buttons used as primary commands are shown in the command bar with both the text label and icon (if both are set).

  XAML

  ```
  <AppBarButton Icon="Copy" Label="Copy"/>
  ```

- **In Windows App SDK 1.4 and earlier:** App bar buttons used as primary commands are shown in the command bar with only their icon; the text label is not shown. We recommend that you use a tooltip to show a text description of the command, as shown here.

  XAML

  ```
  <AppBarButton Icon="Copy" ToolTipService.ToolTip="Copy"/>
  ```

- App bar buttons used as secondary commands are shown in the menu, with both the label and icon visible.

Icons

Consider providing menu item icons for:

- The most commonly used items.
- Menu items whose icon is standard or well known.
- Menu items whose icon well illustrates what the command does.

Don't feel obligated to provide icons for commands that don't have a standard visualization. Cryptic icons aren't helpful, create visual clutter, and prevent users from focusing on the important menu items.

Other content

You can add other controls to a command bar flyout by wrapping them in an AppBarElementContainer. This lets you add controls like DropDownButton or SplitButton, or add containers like StackPanel to create more complex UI.

In order to be added to the primary or secondary command collections of a command bar flyout, an element must implement the ICommandBarElement interface. AppBarElementContainer is a wrapper that implements this interface so you can add an element to a command bar even if it doesn't implement the interface itself.

Here, an AppBarElementContainer is used to add extra elements to a command bar flyout. A SplitButton is added to the primary commands to enable text alignment. A StackPanel is added to the secondary commands to allow a more complex layout for zoom controls.

> **Tip**
>
> By default, elements designed for the app canvas might not look right in a command bar. When you add an element using AppBarElementContainer, there are some steps you should take to make the element match other command bar elements:
>
> - Override the default brushes with **lightweight styling** to make the element's background and border match the app bar buttons.
> - Adjust the size and position of the element.
> - Wrap icons in a Viewbox with a Width and Height of 16px.

> **Note**
>
> This example shows only the command bar flyout UI, it does not implement any of the commands that are shown. For more info about implementing the commands, see Buttons and Command design basics.

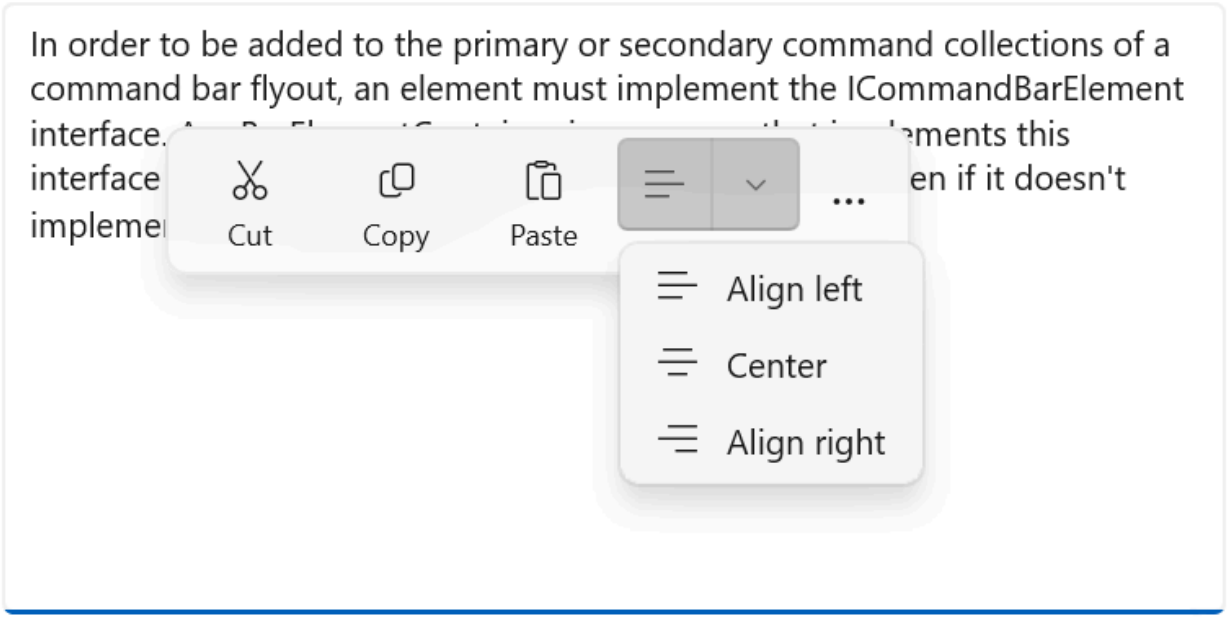
XAML

```
<CommandBarFlyout>
    <AppBarButton Icon="Cut" Label="Cut" ToolTipService.ToolTip="Cut"/>
    <AppBarButton Icon="Copy" Label="Copy" ToolTipService.ToolTip="Copy"/>
    <AppBarButton Icon="Paste" Label="Paste"
ToolTipService.ToolTip="Paste"/>
    <!-- Alignment controls -->
    <AppBarElementContainer>
         <SplitButton ToolTipService.ToolTip="Alignment">
            <SplitButton.Resources>
                <!-- Override default brushes to make the SplitButton
                     match other command bar elements. -->
                <Style TargetType="SplitButton">
                    <Setter Property="Height" Value="38"/>
                </Style>
                <SolidColorBrush x:Key="SplitButtonBackground"
                                 Color="Transparent"/>
                <SolidColorBrush x:Key="SplitButtonBackgroundPressed"
                                 Color="{ThemeResource
SystemListMediumColor}"/>
                <SolidColorBrush x:Key="SplitButtonBackgroundPointerOver"
```

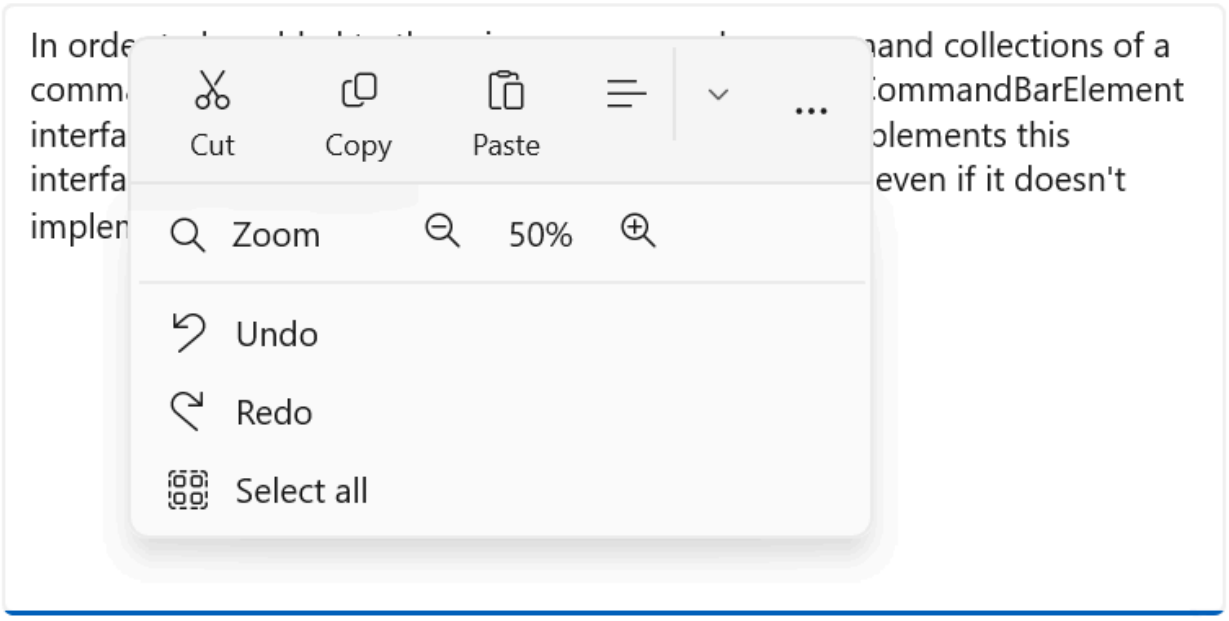
```
                                Color="{ThemeResource
SystemListLowColor}"/>
                <SolidColorBrush x:Key="SplitButtonBorderBrush"
Color="Transparent"/>
                <SolidColorBrush x:Key="SplitButtonBorderBrushPointerOver"
                                 Color="Transparent"/>
                <SolidColorBrush x:Key="SplitButtonBorderBrushChecked"
                                 Color="Transparent"/>
            </SplitButton.Resources>
            <SplitButton.Content>
                <Viewbox Width="16" Height="16" Margin="0,2,0,0">
                    <SymbolIcon Symbol="AlignLeft"/>
                </Viewbox>
            </SplitButton.Content>
            <SplitButton.Flyout>
                <MenuFlyout>
                    <MenuFlyoutItem Icon="AlignLeft" Text="Align left"/>
                    <MenuFlyoutItem Icon="AlignCenter" Text="Center"/>
                    <MenuFlyoutItem Icon="AlignRight" Text="Align right"/>
                </MenuFlyout>
            </SplitButton.Flyout>
        </SplitButton>
    </AppBarElementContainer>
    <!-- end Alignment controls -->
    <CommandBarFlyout.SecondaryCommands>
        <!-- Zoom controls -->
        <AppBarElementContainer>
            <AppBarElementContainer.Resources>
                <!-- Override default brushes to make the Buttons
                     match other command bar elements. -->
                <SolidColorBrush x:Key="ButtonBackground"
                                 Color="Transparent"/>
                <SolidColorBrush x:Key="ButtonBackgroundPressed"
                                 Color="{ThemeResource
SystemListMediumColor}"/>
                <SolidColorBrush x:Key="ButtonBackgroundPointerOver"
                                 Color="{ThemeResource
SystemListLowColor}"/>
                <SolidColorBrush x:Key="ButtonBorderBrush"
                                 Color="Transparent"/>
                <SolidColorBrush x:Key="ButtonBorderBrushPointerOver"
                                 Color="Transparent"/>
                <SolidColorBrush x:Key="ButtonBorderBrushChecked"
                                 Color="Transparent"/>
                <Style TargetType="TextBlock">
                    <Setter Property="VerticalAlignment" Value="Center"/>
                </Style>
                <Style TargetType="Button">
                    <Setter Property="Height" Value="40"/>
                    <Setter Property="Width" Value="40"/>
                </Style>
            </AppBarElementContainer.Resources>
            <Grid Margin="12,-4">
                <Grid.ColumnDefinitions>
                    <ColumnDefinition Width="Auto"/>
```

```
                    <ColumnDefinition Width="76"/>
                    <ColumnDefinition Width="Auto"/>
                </Grid.ColumnDefinitions>
                <Viewbox Width="16" Height="16" Margin="0,2,0,0">
                    <SymbolIcon Symbol="Zoom"/>
                </Viewbox>
                <TextBlock Text="Zoom" Margin="10,0,0,0" Grid.Column="1"/>
                <StackPanel Orientation="Horizontal" Grid.Column="2">
                    <Button ToolTipService.ToolTip="Zoom out">
                        <Viewbox Width="16" Height="16">
                            <SymbolIcon Symbol="ZoomOut"/>
                        </Viewbox>
                    </Button>
                    <TextBlock Text="50%" Width="40"
                               HorizontalTextAlignment="Center"/>
                    <Button ToolTipService.ToolTip="Zoom in">
                        <Viewbox Width="16" Height="16">
                            <SymbolIcon Symbol="ZoomIn"/>
                        </Viewbox>
                    </Button>
                </StackPanel>
            </Grid>
        </AppBarElementContainer>
        <!-- end Zoom controls -->
        <AppBarSeparator/>
        <AppBarButton Label="Undo" Icon="Undo"/>
        <AppBarButton Label="Redo" Icon="Redo"/>
        <AppBarButton Label="Select all" Icon="SelectAll"/>
    </CommandBarFlyout.SecondaryCommands>
</CommandBarFlyout>
```

Here's the collapsed command bar flyout with an open SplitButton.



Here's the expanded command bar flyout with custom zoom UI in the menu.



Create a context menu with secondary commands only

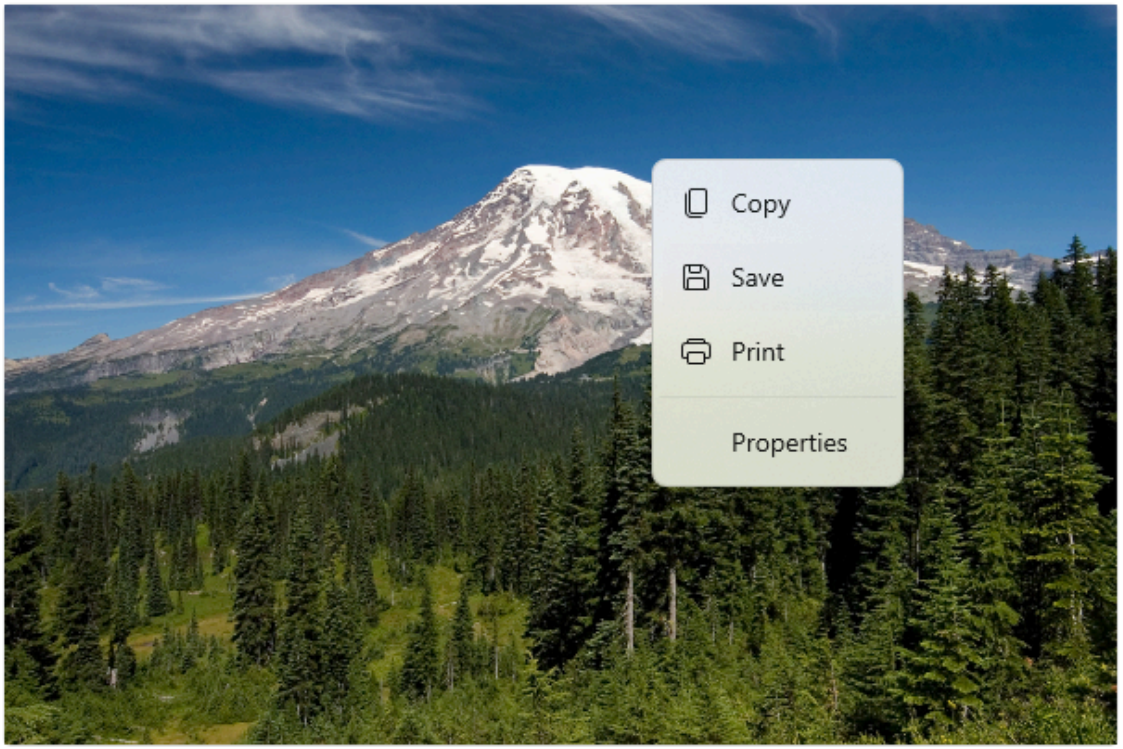
You can use a command bar flyout with only secondary commands to create a context menu that achieves the same look and behavior of menu flyout.

XAML

```
<Grid>
    <Grid.Resources>
        <!-- A command bar flyout with only secondary commands. -->
        <CommandBarFlyout x:Name="ContextMenu">
            <CommandBarFlyout.SecondaryCommands>
                <AppBarButton Label="Copy" Icon="Copy"/>
                <AppBarButton Label="Save" Icon="Save"/>
                <AppBarButton Label="Print" Icon="Print"/>
                <AppBarSeparator />
                <AppBarButton Label="Properties"/>
            </CommandBarFlyout.SecondaryCommands>
        </CommandBarFlyout>
    </Grid.Resources>

    <Image Source="Assets/image1.png" Width="300"
           ContextFlyout="{x:Bind ContextMenu}"/>
</Grid>
```

Here's the command bar flyout as a context menu.



You can also use a CommandBarFlyout with a DropDownButton to create a standard menu.

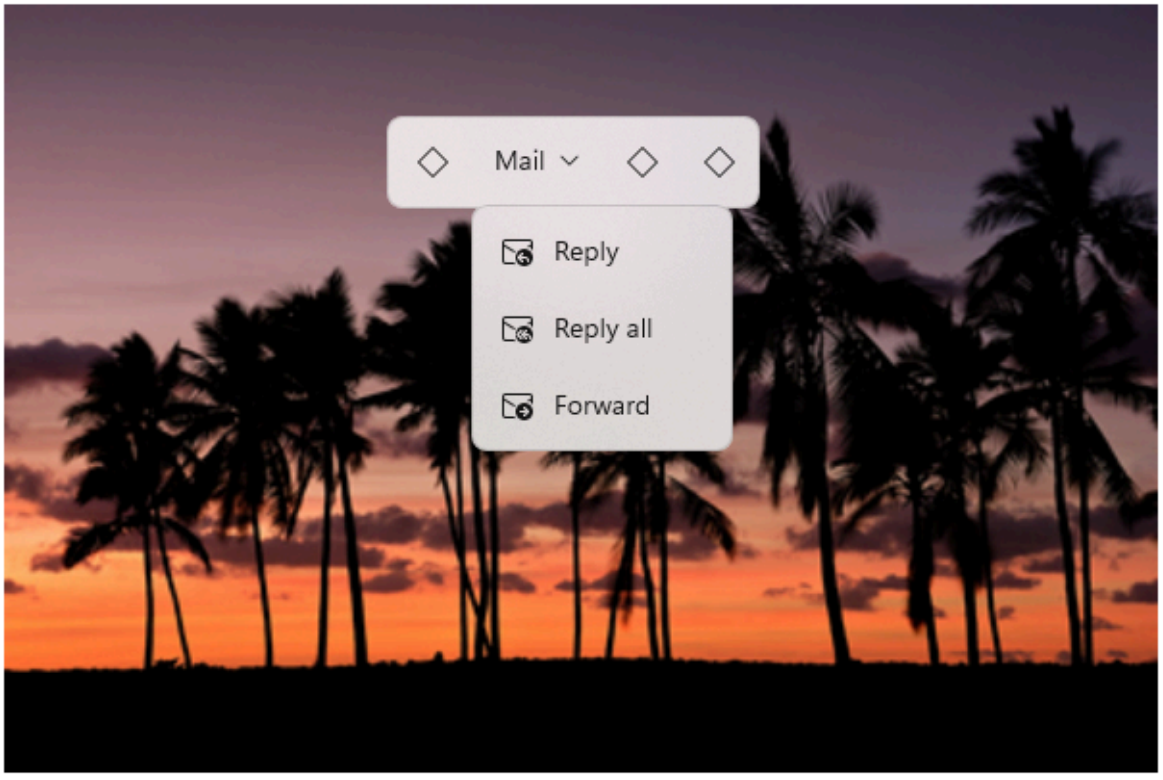
XAML

```
<CommandBarFlyout>
    <AppBarButton Icon="Placeholder"/>
    <AppBarElementContainer>
        <DropDownButton Content="Mail">
            <DropDownButton.Resources>
                <!-- Override default brushes to make the DropDownButton
                     match other command bar elements. -->
                <Style TargetType="DropDownButton">
                    <Setter Property="Height" Value="38"/>
                </Style>
                <SolidColorBrush x:Key="ButtonBackground"
                                 Color="Transparent"/>
                <SolidColorBrush x:Key="ButtonBackgroundPressed"
                                 Color="{ThemeResource
SystemListMediumColor}"/>
                <SolidColorBrush x:Key="ButtonBackgroundPointerOver"
                                 Color="{ThemeResource
SystemListLowColor}"/>

                <SolidColorBrush x:Key="ButtonBorderBrush"
                                 Color="Transparent"/>
                <SolidColorBrush x:Key="ButtonBorderBrushPointerOver"
                                 Color="Transparent"/>
                <SolidColorBrush x:Key="ButtonBorderBrushChecked"
                                 Color="Transparent"/>
```

```
            </DropDownButton.Resources>
            <DropDownButton.Flyout>
                <CommandBarFlyout Placement="BottomEdgeAlignedLeft">
                    <CommandBarFlyout.SecondaryCommands>
                        <AppBarButton Icon="MailReply" Label="Reply"/>
                        <AppBarButton Icon="MailReplyAll" Label="Reply
all"/>
                        <AppBarButton Icon="MailForward" Label="Forward"/>
                    </CommandBarFlyout.SecondaryCommands>
                </CommandBarFlyout>
            </DropDownButton.Flyout>
        </DropDownButton>
    </AppBarElementContainer>
    <AppBarButton Icon="Placeholder"/>
    <AppBarButton Icon="Placeholder"/>
</CommandBarFlyout>
```

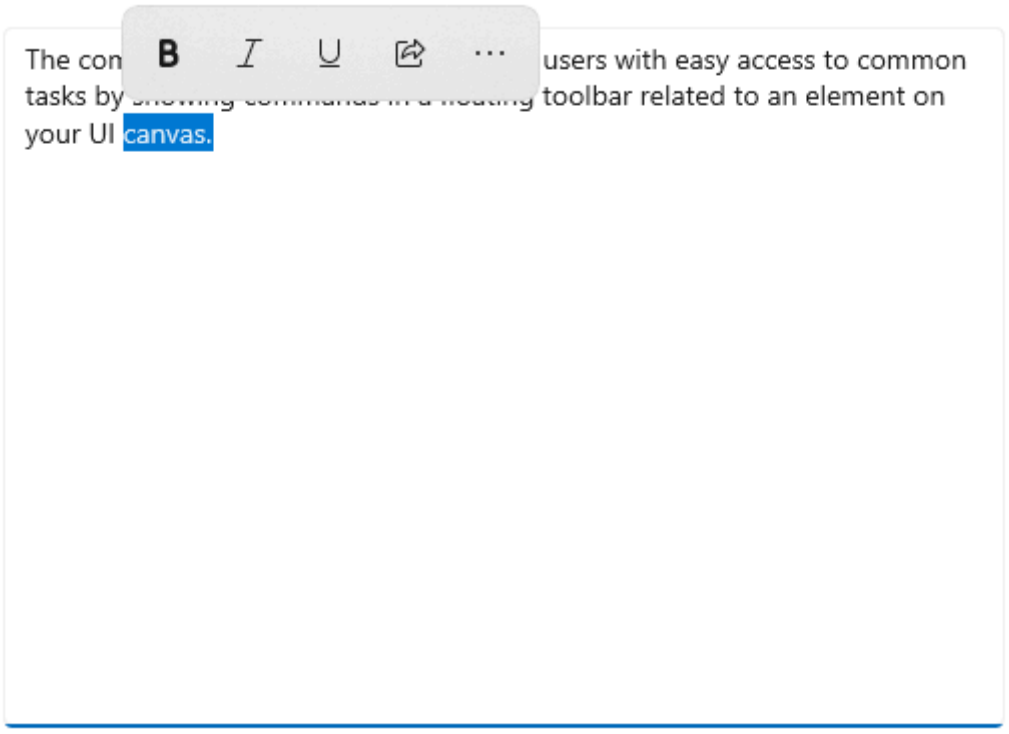
Here's a drop down button menu in a command bar flyout.



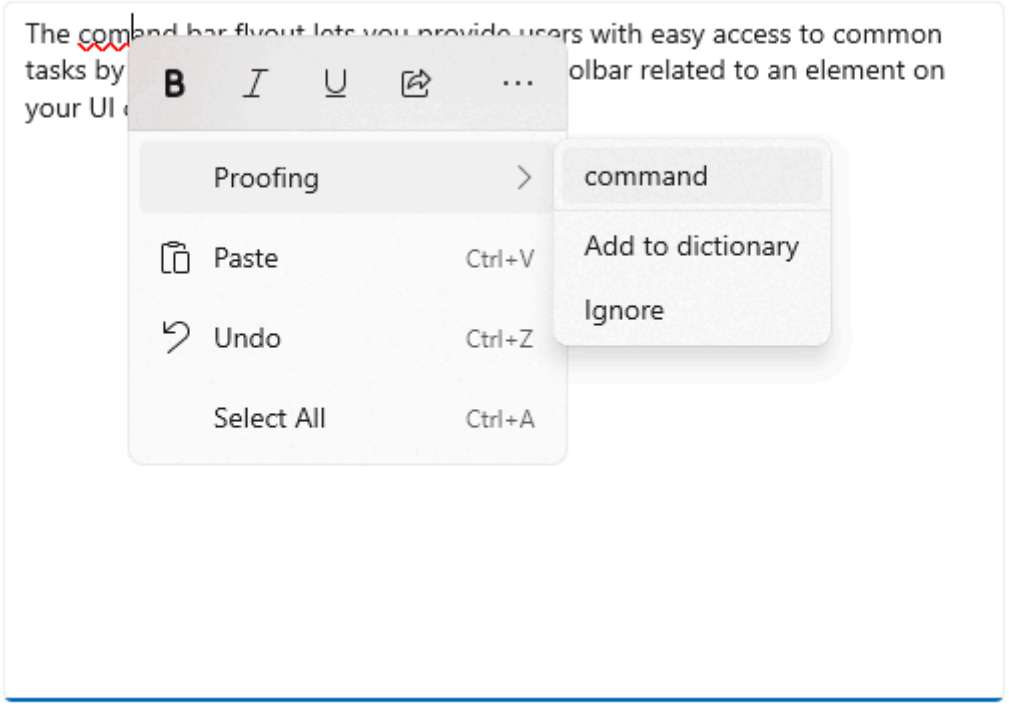
Command bar flyouts for text controls

The TextCommandBarFlyout is a specialized command bar flyout that contains commands for editing text. Each text control shows the TextCommandBarFlyout automatically as a context menu (right-click), or when text is selected. The text command bar flyout adapts to the text selection to only show relevant commands.

Here's a text command bar flyout on text selection.



Here's an expanded text command bar flyout that shows the secondary commands.



Available commands

This table shows the commands that are included in a TextCommandBarFlyout, and when they are shown.

Expand table

Command	Shown...
Bold	when the text control is not read-only (RichEditBox only).
Italic	when the text control is not read-only (RichEditBox only).
Underline	when the text control is not read-only (RichEditBox only).
Proofing	when IsSpellCheckEnabled is **true** and misspelled text is selected.
Cut	when the text control is not read-only and text is selected.
Copy	when text is selected.
Paste	when the text control is not read-only and the clipboard has content.
Undo	when there is an action that can be undone.
Select all	when text can be selected.

Custom text command bar flyouts

TextCommandBarFlyout can't be customized, and is managed automatically by each text control. However, you can replace the default TextCommandBarFlyout with custom commands.

- To replace the default TextCommandBarFlyout that's shown on text selection, you can create a custom CommandBarFlyout (or other flyout type) and assign it to the **SelectionFlyout** property. If you set SelectionFlyout to **null**, no commands are shown on selection.
- To replace the default TextCommandBarFlyout that's shown as the context menu, assign a custom CommandBarFlyout (or other flyout type) to the **ContextFlyout** property on a text control. If you set ContextFlyout to **null**, the menu flyout shown in previous versions of the text control is shown instead of the TextCommandBarFlyout.

Light dismiss

Light dismiss controls–such as menus, context menus, and other flyouts–trap keyboard and gamepad focus inside the transient UI until dismissed. To provide a visual cue for

this behavior, light dismiss controls on Xbox will draw an overlay that dims the visibility of out of scope UI. This behavior can be modified with the LightDismissOverlayMode property. By default, transient UIs will draw the light dismiss overlay on Xbox (**Auto**) but not other device families. You can choose to force the overlay to be always **On** or always **Off**.

XAML

```
<CommandBarFlyout LightDismissOverlayMode="Off" /> >
```

UWP and WinUI 2

> **ⓘ Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

The CommandBarFlyout control for UWP apps is included as part of WinUI 2. For more info, including installation instructions, see WinUI 2. APIs for this control exist in both the Windows.UI.Xaml.Controls (UWP) and Microsoft.UI.Xaml.Controls (WinUI) namespaces.

- ✓ **UWP APIs:** CommandBarFlyout class, TextCommandBarFlyout class, AppBarButton class, AppBarToggleButton class, AppBarSeparator class
- ✓ **WinUI 2 Apis:** CommandBarFlyout class, TextCommandBarFlyout class
- ✓ Open the WinUI 2 Gallery app and see the CommandBarFlyout in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles and templates for all controls. WinUI 2.2 or later includes a new template for this control that uses rounded corners. For more info, see Corner radius.

To use the code in this article with WinUI 2, use an alias in XAML (we use `muxc`) to represent the Windows UI Library APIs that are included in your project. See Get Started

with WinUI 2 for more info.

XAML

```
xmlns:muxc="using:Microsoft.UI.Xaml.Controls"

<muxc:CommandBarFlyout />
```

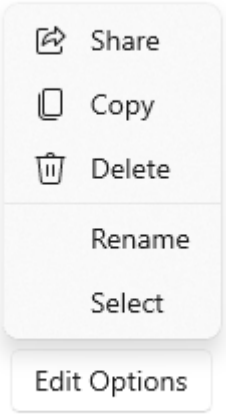
Menu flyout and menu bar

Article • 02/26/2025

Menu flyouts are used in menu and context menu scenarios to display a list of commands or options when requested by the user. A menu flyout shows a single, inline, top-level menu that can have menu items and sub-menus. To show a set of multiple top-level menus in a horizontal row, use menu bar (which you typically position at the top of the app window).



Is this the right control?

See menus and context menus for help identifying menu vs. context menu scenarios and guidance on when to use menu flyout vs. command bar flyout.

Menu flyouts can be used as menus and context menus to organize commands. To display arbitrary content, such as a notification or confirmation request, use a dialog or a flyout.

If a particular command will be used frequently and you have the space available, see collection commanding for examples on placing a command directly in its own element so that users don't have to go through a menu to get to it.

Create a menu flyout

- ✓ **Important APIs:** MenuFlyout class, ContextFlyout property, FlyoutBase.AttachedFlyout property

Open the WinUI 3 Gallery app and see MenuFlyout in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

To create a menu flyout, you use the MenuFlyout class. You define the contents of the menu by adding MenuFlyoutItem, MenuFlyoutSubItem, ToggleMenuFlyoutItem, RadioMenuFlyoutItem and MenuFlyoutSeparator objects to the MenuFlyout.

These objects are for:

- MenuFlyoutItem—Performing an immediate action.
- MenuFlyoutSubItem—Containing a cascading list of menu items.
- ToggleMenuFlyoutItem—Switching an option on or off.
- RadioMenuFlyoutItem—Switching between mutually-exclusive menu items.
- MenuFlyoutSeparator—Visually separating menu items.

This example creates a MenuFlyout and uses the ContextFlyout property, a property available to most controls, to show the MenuFlyout as a context menu.

XAML

```
<Rectangle
  Height="100" Width="100">
  <Rectangle.ContextFlyout>
    <MenuFlyout>
      <MenuFlyoutItem Text="Change color" Click="ChangeColorItem_Click" />
    </MenuFlyout>
  </Rectangle.ContextFlyout>
  <Rectangle.Fill>
    <SolidColorBrush x:Name="rectangleFill" Color="Red" />
  </Rectangle.Fill>
</Rectangle>
```

C#

```
private void ChangeColorItem_Click(object sender, RoutedEventArgs e)
{
    // Change the color from red to blue or blue to red.
    if (rectangleFill.Color == Windows.UI.Colors.Red)
    {
        rectangleFill.Color = Windows.UI.Colors.Blue;
    }
    else
    {
        rectangleFill.Color = Windows.UI.Colors.Red;
```

```
    }
}
```

The next example is nearly identical, but instead of using the ContextFlyout property to show the MenuFlyout class as a context menu, the example uses the FlyoutBase.ShowAttachedFlyout property to show it as a menu.

XAML

```
<Rectangle
  Height="100" Width="100"
  Tapped="Rectangle_Tapped">
  <FlyoutBase.AttachedFlyout>
    <MenuFlyout>
      <MenuFlyoutItem Text="Change color" Click="ChangeColorItem_Click" />
    </MenuFlyout>
  </FlyoutBase.AttachedFlyout>
  <Rectangle.Fill>
    <SolidColorBrush x:Name="rectangleFill" Color="Red" />
  </Rectangle.Fill>
</Rectangle>
```

C#

```
private void Rectangle_Tapped(object sender, TappedRoutedEventArgs e)
{
    FlyoutBase.ShowAttachedFlyout((FrameworkElement)sender);
}

private void ChangeColorItem_Click(object sender, RoutedEventArgs e)
{
    // Change the color from red to blue or blue to red.
    if (rectangleFill.Color == Windows.UI.Colors.Red)
    {
        rectangleFill.Color = Windows.UI.Colors.Blue;
    }
    else
    {
        rectangleFill.Color = Windows.UI.Colors.Red;
    }
}
```

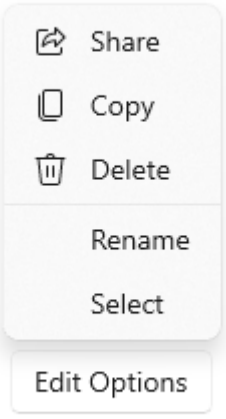
Icons

Consider providing menu item icons for:

- The most commonly used items.
- Menu items whose icon is standard or well known.

- Menu items whose icon well illustrates what the command does.

Don't feel obligated to provide icons for commands that don't have a standard visualization. Cryptic icons aren't helpful, create visual clutter, and prevent users from focusing on the important menu items.



XAML

```
<MenuFlyout>
  <MenuFlyoutItem Text="Share" >
    <MenuFlyoutItem.Icon>
      <FontIcon Glyph="&#xE72D;" />
    </MenuFlyoutItem.Icon>
  </MenuFlyoutItem>
  <MenuFlyoutItem Text="Copy" Icon="Copy" />
  <MenuFlyoutItem Text="Delete" Icon="Delete" />
  <MenuFlyoutSeparator />
  <MenuFlyoutItem Text="Rename" />
  <MenuFlyoutItem Text="Select" />
</MenuFlyout>
```

Tip

The size of the icon in a MenuFlyoutItem is 16x16px. If you use SymbolIcon, FontIcon, or PathIcon, the icon automatically scales to the correct size with no loss of fidelity. If you use BitmapIcon, ensure that your asset is 16x16px.

Light dismiss

Light dismiss controls such as menus, context menus, and other flyouts, trap keyboard and gamepad focus inside the transient UI until dismissed. To provide a visual cue for

this behavior, light dismiss controls on Xbox will draw an overlay that dims the visibility of out of scope UI. This behavior can be modified with the LightDismissOverlayMode property. By default, transient UIs will draw the light dismiss overlay on Xbox (**Auto**) but not other device families. You can choose to force the overlay to be always **On** or always **Off**.

XAML

```
<MenuFlyout LightDismissOverlayMode="Off" />
```

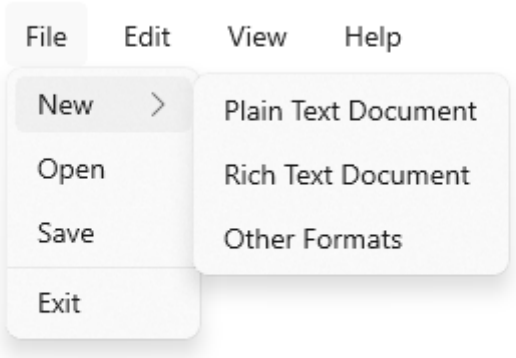
Create a menu bar

✔ **Important APIs:** MenuBar class. MenuBarItem class

Open the WinUI 3 Gallery app and see MenuBar in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

You use the same elements to create menus in a menu bar as in a menu flyout. However, instead of grouping MenuFlyoutItem objects in a MenuFlyout, you group them in a MenuBarItem element. Each MenuBarItem is added to the MenuBar as a top level menu.



> ⓘ **Note**
>
> This example shows only how to create the UI structure, but does not show implementation of any of the commands.

XAML

```
<muxc:MenuBar>
    <muxc:MenuBarItem Title="File">
        <MenuFlyoutSubItem Text="New">
            <MenuFlyoutItem Text="Plain Text Document"/>
            <MenuFlyoutItem Text="Rich Text Document"/>
            <MenuFlyoutItem Text="Other Formats..."/>
        </MenuFlyoutSubItem>
        <MenuFlyoutItem Text="Open..."/>
        <MenuFlyoutItem Text="Save"/>
        <MenuFlyoutSeparator />
        <MenuFlyoutItem Text="Exit"/>
    </muxc:MenuBarItem>

    <muxc:MenuBarItem Title="Edit">
        <MenuFlyoutItem Text="Undo"/>
        <MenuFlyoutItem Text="Cut"/>
        <MenuFlyoutItem Text="Copy"/>
        <MenuFlyoutItem Text="Paste"/>
    </muxc:MenuBarItem>

    <muxc:MenuBarItem Title="View">
        <MenuFlyoutItem Text="Output"/>
        <MenuFlyoutSeparator/>
        <muxc:RadioMenuFlyoutItem Text="Landscape"
GroupName="OrientationGroup"/>
        <muxc:RadioMenuFlyoutItem Text="Portrait"
GroupName="OrientationGroup" IsChecked="True"/>
        <MenuFlyoutSeparator/>
        <muxc:RadioMenuFlyoutItem Text="Small icons" GroupName="SizeGroup"/>
        <muxc:RadioMenuFlyoutItem Text="Medium icons" IsChecked="True"
GroupName="SizeGroup"/>
        <muxc:RadioMenuFlyoutItem Text="Large icons" GroupName="SizeGroup"/>
    </muxc:MenuBarItem>

    <muxc:MenuBarItem Title="Help">
        <MenuFlyoutItem Text="About"/>
    </muxc:MenuBarItem>
</muxc:MenuBar>
```

UWP and WinUI 2

> **ⓘ Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.

This section contains information you need to use the control in a UWP or WinUI 2 app.

MenuBar requires Windows 10, version 1809 (SDK 17763) or later, or WinUI 2.

The MenuFlyout and MenuBar controls for UWP apps are included as part of WinUI 2. For more info, including installation instructions, see WinUI 2. APIs for these controls exist in both the Windows.UI.Xaml.Controls and Microsoft.UI.Xaml.Controls namespaces.

- ✓ **UWP APIs:** MenuFlyout class, MenuBar class, ContextFlyout property, FlyoutBase.AttachedFlyout property
- ✓ **WinUI 2 Apis:** MenuBar class, ContextFlyout property, FlyoutBase.AttachedFlyout property
- ✓ Open the WinUI 2 Gallery app and see MenuBar in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles and templates for all controls. WinUI 2.2 or later includes a new template for these controls that uses rounded corners. For more info, see Corner radius.

To use the code in this article with WinUI 2, use an alias in XAML (we use `muxc`) to represent the Windows UI Library APIs that are included in your project. See Get Started with WinUI 2 for more info.

XAML

```
xmlns:muxc="using:Microsoft.UI.Xaml.Controls"

<muxc:MenuFlyout />
<muxc:MenuBar />
```

Breadcrumb Bar

Article • 02/26/2025

A BreadcrumbBar provides the direct path of pages or folders to the current location. It is often used for situations where the user's navigation trail (in a file system or menu system) needs to be persistently visible and the user may need to go back to a previous location.

Is this the right control?

A breadcrumb bar lets a user keep track of their location when navigating through an app or folders, and lets them quickly jump back to a previous location in the path.

Use a BreadcrumbBar when the path taken to the current position is relevant. This UI is commonly used in folder managers and when a user may navigate many levels deep into an app.

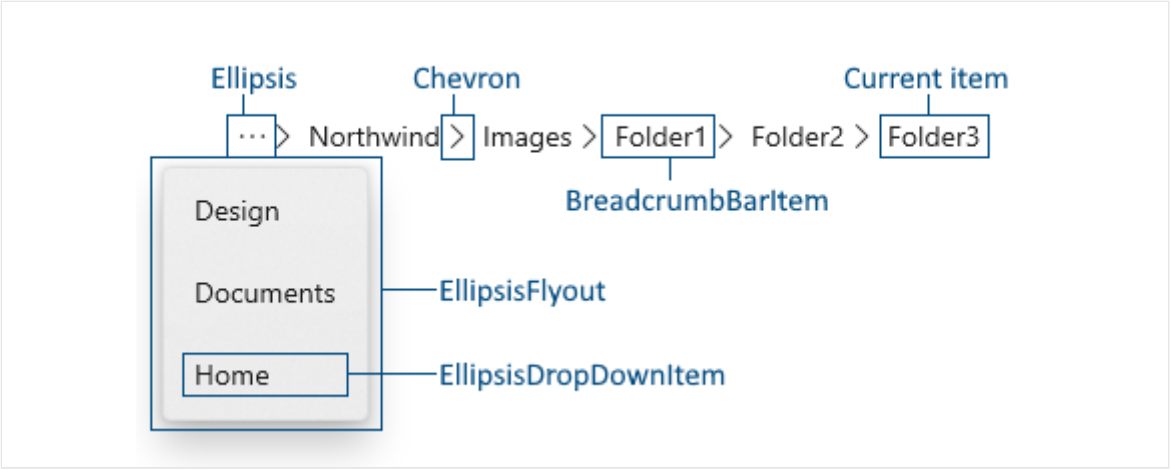
Breadcrumb bar UI

The breadcrumb bar displays each node in a horizontal line, separated by chevrons.

If the app is resized so that there is not enough space to show all the nodes, the breadcrumbs collapse and an ellipsis replaces the leftmost nodes. Clicking the ellipsis opens a flyout to show the collapsed nodes.

Anatomy

The image below shows the parts of the `BreadcrumbBar` control. You can modify the appearance of some parts by using lightweight styling.



Recommendations

- Use a breadcrumb bar when you have many levels of navigation and expect users to be able to return to any previous level.
- Don't use a breadcrumb bar if you only have 2 possible levels of navigation. Simple back navigation is sufficient.
- Show the current location as the last item in the breadcrumb bar. However, you typically don't want to perform any navigation if the user clicks the current item. (If you want to let the user reload the current page or data, consider providing a dedicated 'reload' option.)

Create a breadcrumb bar

✓ **Important APIs:** BreadcrumbBar class

Open the WinUI 3 Gallery app and see the BreadcrumbBar in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

This example shows how to create a breadcrumb bar with the default styling. You can place the breadcrumb bar anywhere in your app UI. You populate the breadcrumbs by setting the ItemsSource property. Here, it's set to an array of strings that are shown in the breadcrumb bar.

XAML

```
<BreadcrumbBar x:Name="BreadcrumbBar1"/>
```

C#

```
BreadcrumbBar1.ItemsSource =
   new string[] { "Home", "Documents", "Design", "Northwind", "Images",
"Folder1", "Folder2", "Folder3" };
```

ItemsSource

The breadcrumb bar does not have an `Items` property, it only has an ItemsSource property. This means you can't populate the breadcrumbs in XAML or by adding them directly to an `Items` collection in code. Instead, you create a collection and connect the `ItemsSource` property to it in code or using data binding.

You can set the ItemsSource to a collection of any type of data to suit the needs of your app. The data items in the collection are used both to display the breadcrumb in the bar, and to navigate when an item in the breadcrumb bar is clicked. In the examples on this page, we create a simple `struct` (named `Crumb`) that contains a label to display in the breadcrumb bar and a data object that holds information used for navigation.

C#

```
public readonly struct Crumb
{
    public Crumb(String label, object data)
    {
        Label = label;
        Data = data;
    }
    public string Label { get; }
    public object Data { get; }
    public override string ToString() => Label;
}
```

ItemTemplate

By default, the breadcrumb bar displays the string representation of each item in the collection. If the data items in your collection don't have an appropriate `ToString` override, you can use the ItemTemplate property to specify a data template that defines how the items are shown in the breadcrumb bar.

For example, if your breadcrumb collection was a list of StorageFolder objects, you could provide a data template and bind to the DisplayName property like this.

C#

```
ObservableCollection<StorageFolder> Breadcrumbs =
    new ObservableCollection<StorageFolder>();
```

XAML

```
<BreadcrumbBar x:Name="FolderBreadcrumbBar"
               ItemsSource="{x:Bind Breadcrumbs}">
    <BreadcrumbBar.ItemTemplate>
        <DataTemplate x:DataType="StorageFolder">
            <TextBlock Text="{x:Bind DisplayName}"/>
        </DataTemplate>
    </BreadcrumbBar.ItemTemplate>
</BreadcrumbBar>
```

ItemClicked

Handle the ItemClicked event to navigate to the item the user has clicked in the breadcrumb bar. The current location is typically shown as the last item in the breadcrumb bar, so you should include a check in your event handler if you don't want to reload the current location.

This example checks the Index to see whether the clicked Item is the last item in the collection, which is the current location. If it is, no navigation occurs.

C#

```
// Breadcrumbs is set as BreadcrumbBar1.ItemsSource.
List<Crumb> Breadcrumbs = new List<Crumb>();

...

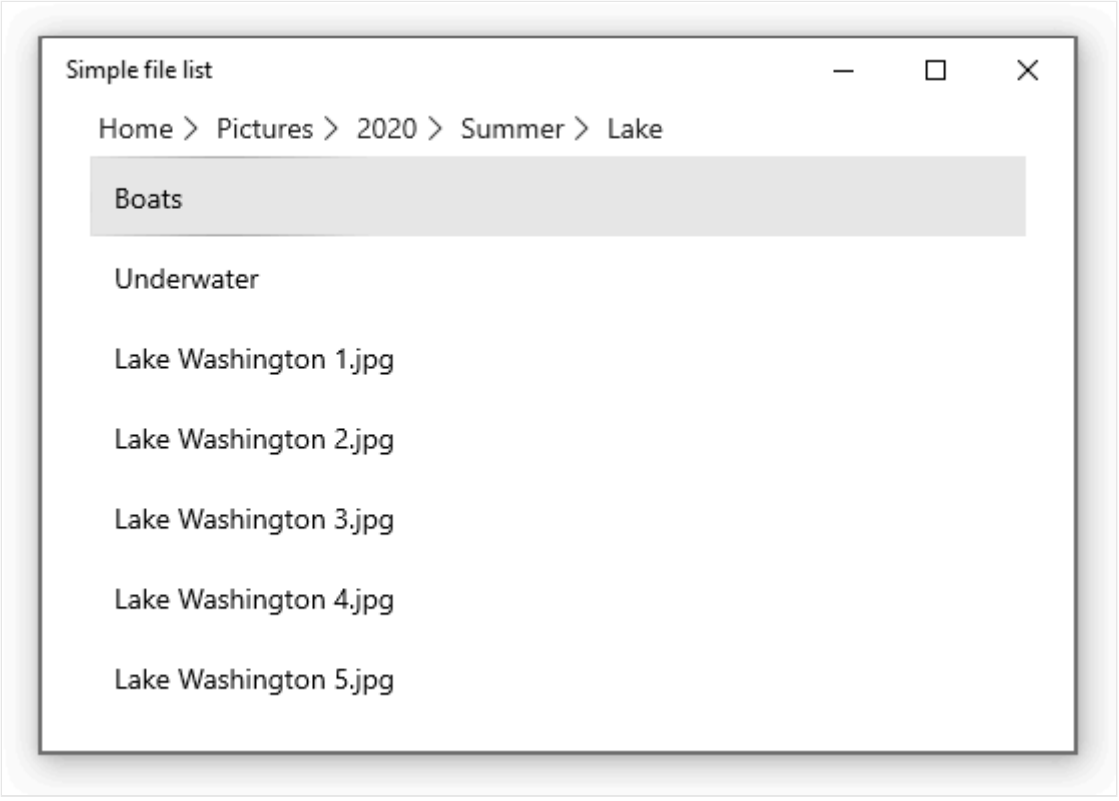
private void BreadcrumbBar1_ItemClicked(muxc.BreadcrumbBar sender,
muxc.BreadcrumbBarItemClickedEventArgs args)
{
    if (args.Index < Breadcrumbs.Count - 1)
    {
        var crumb = (Crumb)args.Item;
        Frame.Navigate((Type)crumb.Data);
    }
}
```

Lightweight styling

You can modify the default Style and ControlTemplate to give the control a unique appearance. See the Control Style and Template section of the BreadcrumbBar API docs for a list of the available theme resources. For more info, see the Light-weight styling section of the Styling controls article.

Code examples

This example shows how you could use a breadcrumb bar in a simple file explorer scenario. The list view shows the contents of the selected Pictures or Music library, and lets the user drill down into sub-folders. The breadcrumb bar is placed in the header of the list view, and shows the path to the current folder.



XAML

```
<Grid>
   <ListView x:Name="FolderListView" Margin="24,0"
             IsItemClickEnabled="True"
             ItemClick="FolderListView_ItemClick">
      <ListView.Header>
         <BreadcrumbBar x:Name="FolderBreadcrumbBar"
                        ItemsSource="{x:Bind Breadcrumbs}"
                        ItemClicked="FolderBreadcrumbBar_ItemClicked">
         </BreadcrumbBar>
      </ListView.Header>
      <ListView.ItemTemplate>
```

```
          <DataTemplate>
             <TextBlock Text="{Binding Name}"/>
             </DataTemplate>
       </ListView.ItemTemplate>
    </ListView>
</Grid>
```

C#

```
public sealed partial class MainPage : Page
{
    List<IStorageItem> Items;
    ObservableCollection<object> Breadcrumbs =
        new ObservableCollection<object>();

    public MainPage()
    {
        this.InitializeComponent();
        InitializeView();
    }

    private void InitializeView()
    {
        // Start with Pictures and Music libraries.
        Items = new List<IStorageItem>();
        Items.Add(KnownFolders.PicturesLibrary);
        Items.Add(KnownFolders.MusicLibrary);
        FolderListView.ItemsSource = Items;

        Breadcrumbs.Clear();
        Breadcrumbs.Add(new Crumb("Home", null));
    }

    private async void FolderBreadcrumbBar_ItemClicked(muxc.BreadcrumbBar
sender, muxc.BreadcrumbBarItemClickedEventArgs args)
    {
        // Don't process last index (current location)
        if (args.Index < Breadcrumbs.Count - 1)
        {
            // Home is special case.
            if (args.Index == 0)
            {
                InitializeView();
            }
            // Go back to the clicked item.
            else
            {
                var crumb = (Crumb)args.Item;
                await GetFolderItems((StorageFolder)crumb.Data);

                // Remove breadcrumbs at the end until
                // you get to the one that was clicked.
                while (Breadcrumbs.Count > args.Index + 1)
```

```
                {
                    Breadcrumbs.RemoveAt(Breadcrumbs.Count - 1);
                }
            }
        }
    }

    private async void FolderListView_ItemClick(object sender,
ItemClickEventArgs e)
    {
        // Ignore if a file is clicked.
        // If a folder is clicked, drill down into it.
        if (e.ClickedItem is StorageFolder)
        {
            StorageFolder folder = e.ClickedItem as StorageFolder;
            await GetFolderItems(folder);
            Breadcrumbs.Add(new Crumb(folder.DisplayName, folder));
        }
    }

    private async Task GetFolderItems(StorageFolder folder)
    {
        IReadOnlyList<IStorageItem> itemsList = await
folder.GetItemsAsync();
        FolderListView.ItemsSource = itemsList;
    }
}

public readonly struct Crumb
{
    public Crumb(String label, object data)
    {
        Label = label;
        Data = data;
    }
    public string Label { get; }
    public object Data { get; }
    public override string ToString() => Label;
}
```

UWP and WinUI 2

> **ⓘ Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.

This section contains information you need to use the control in a UWP or WinUI 2 app.

The BreadcrumbBar for UWP apps requires WinUI 2. For more info, including installation instructions, see WinUI 2. APIs for this control exist in the Microsoft.UI.Xaml.Controls namespace.

- ✓ **WinUI 2 Apis:** BreadcrumbBar class
- ✓ Open the WinUI 2 Gallery app and see the BreadcrumbBar in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

To use the code in this article with WinUI 2, use an alias in XAML (we use `muxc`) to represent the Windows UI Library APIs that are included in your project. See Get Started with WinUI 2 for more info.

XAML

```
xmlns:muxc="using:Microsoft.UI.Xaml.Controls"

<muxc:BreadcrumbBar />
```

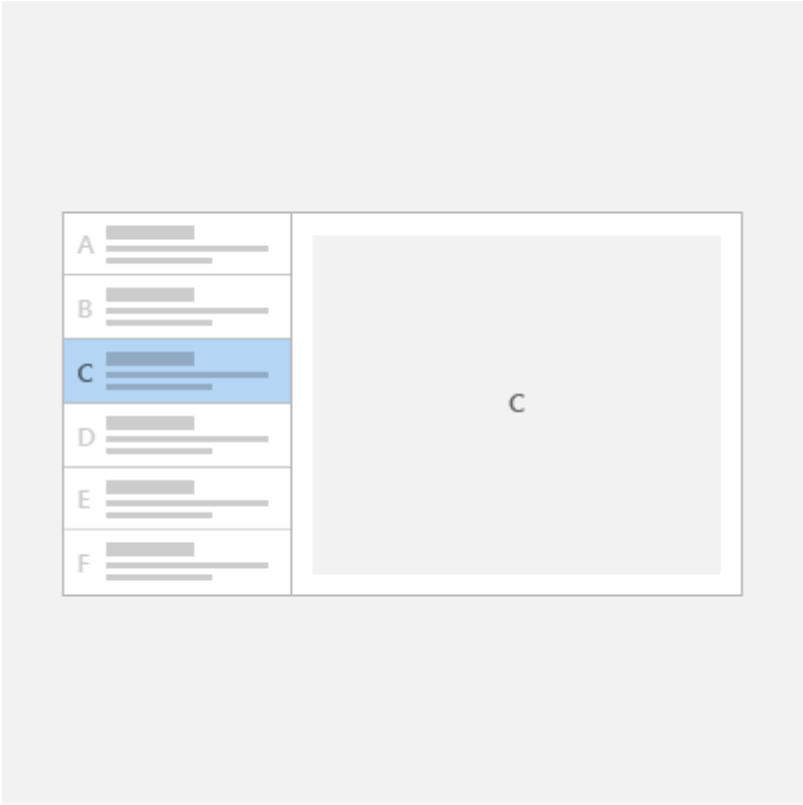
List/details pattern

Article • 06/09/2022

The list/details pattern has a list pane (usually with a list view) and a details pane for content. When an item in the list is selected, the details pane is updated. This pattern is frequently used for email and address books.

> **Important APIs**: ListView class, SplitView class



Tip

If you'd like to use a XAML control that implements this pattern for you, we recommend the **ListDetailsView XAML Control** from the Windows Community Toolkit.

Is this the right pattern?

The list/details pattern works well if you want to:

- Build an email app, address book, or any app that is based on a list-details layout.
- Locate and prioritize a large collection of content.

- Allow the quick addition and removal of items from a list while working back-and-forth between contexts.

Choose the right style

When implementing the list/details pattern, we recommend that you use either the stacked style or the side-by-side style, based on the amount of available screen space.

Available window width	Recommended style
320 epx-640 epx	Stacked
641 epx or wider	Side-by-side

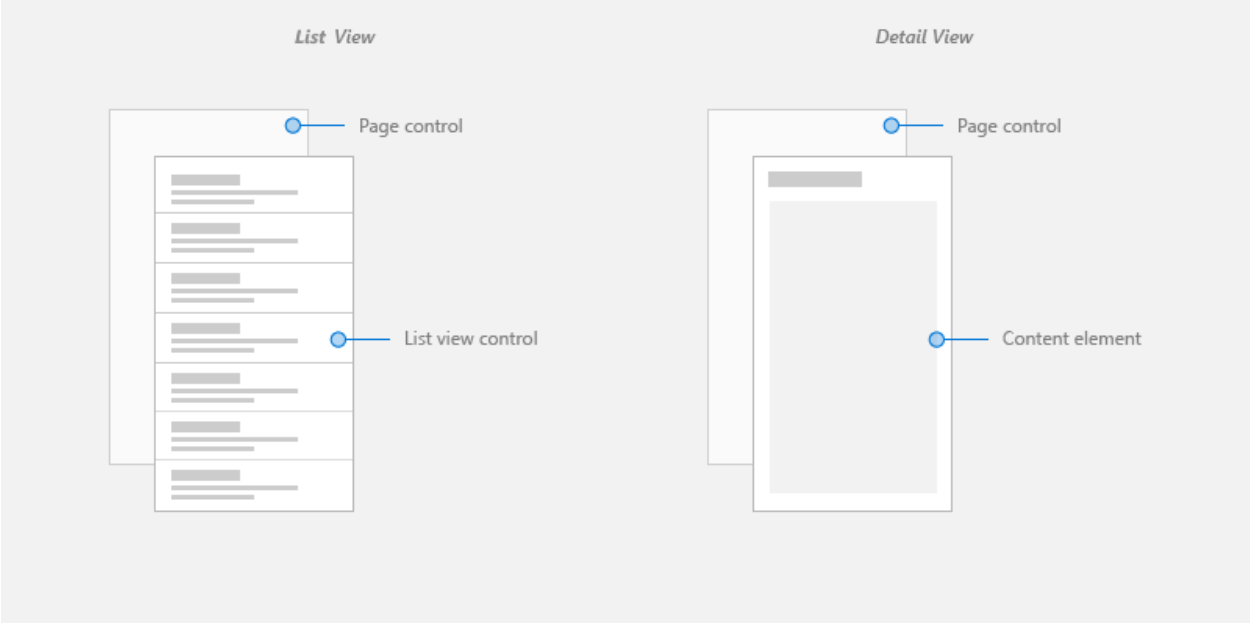
Stacked style

In the stacked style, only one pane is visible at a time: the list or the details.

The user starts at the list pane and "drills down" to the details pane by selecting an item in the list. To the user, it appears as though the list and details views exist on two separate pages.

Create a stacked list/details pattern

One way to create the stacked list/details pattern is to use separate pages for the list pane and the details pane. Place the list view on one page, and the details pane on a separate page.



For the list view page, a list view control works well for presenting lists that can contain images and text.

For the details view page, use the content element that makes the most sense. If you have a lot of separate fields, consider using a **Grid** layout to arrange elements into a form.

For navigation between pages, see navigation history and backwards navigation for Windows apps.

Side-by-side style

In the side-by-side style, the list pane and details pane are visible at the same time.

The list in the list pane has a selection visual to indicate the currently selected item. Selecting a new item in the list updates the details pane.

Create a side-by-side list/details pattern

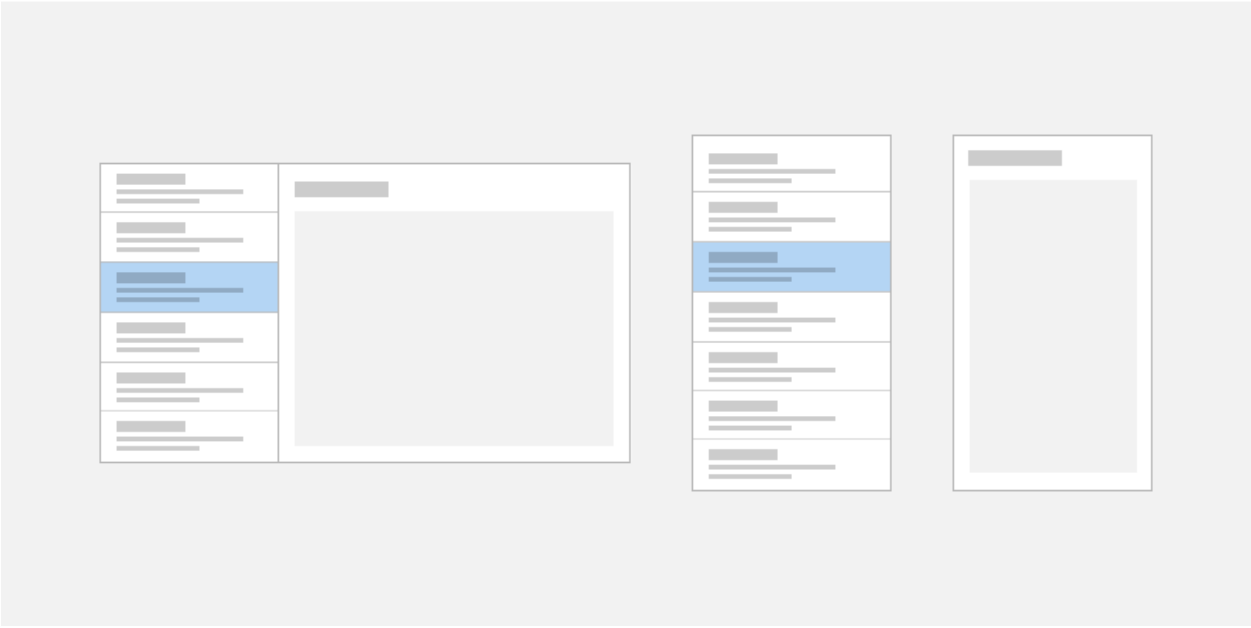
One way to create a side-by-side list/details pattern is to use the split view control. Place the list view in the split view pane, and the details view in the split view content.

For the list pane, a list view control works well for presenting lists that can contain images and text.

For the details content, use the content element that makes the most sense. If you have a lot of separate fields, consider using a **Grid** layout to arrange elements into a form.

Adaptive layout

To implement a list/details pattern for any screen size, create a responsive UI with an adaptive layout.



Create an adaptive list/details pattern

To create an adaptive layout, define different **VisualStates** for your UI, and declare breakpoints for the different states with **AdaptiveTriggers**.

Get the sample code

The following samples implement the list/details pattern with adaptive layouts and demonstrate data binding to static, database, and online resources:

- Master/detail sample
- ListView and GridView sample
- Customer orders database sample
- RSS Reader sample

> **Tip**
>
> If you'd like to use a XAML control that implements this pattern for you, we recommend the **ListDetailsView XAML Control** from the Windows Community

Toolkit.

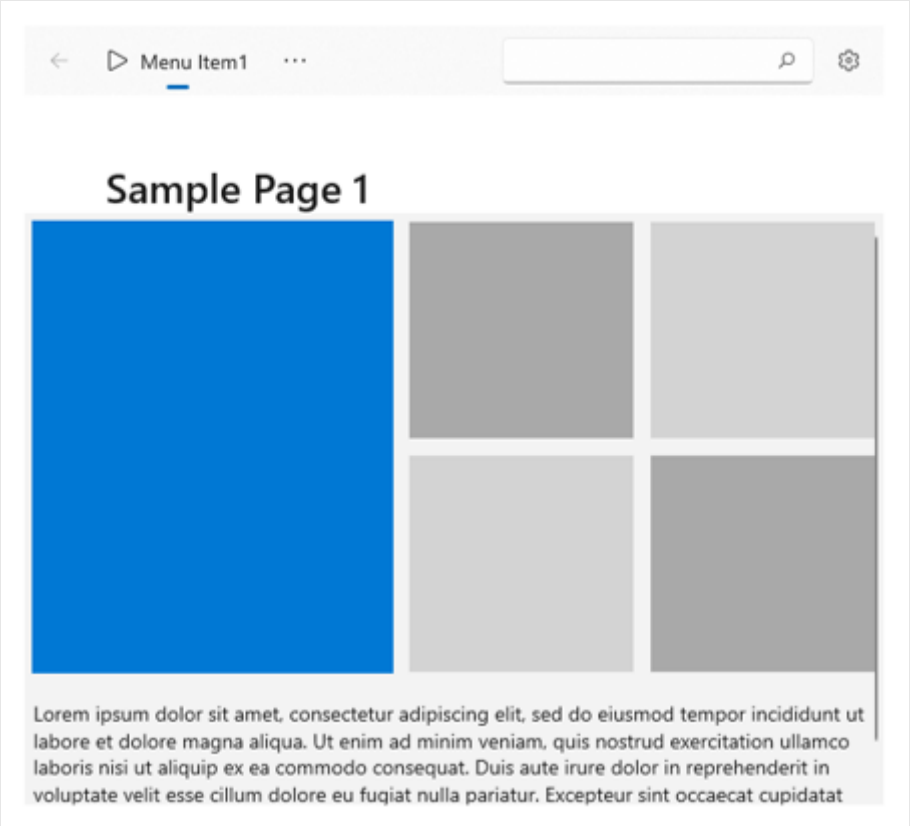
NavigationView

Article • 02/26/2025

The NavigationView control provides top-level navigation for your app. It adapts to a variety of screen sizes and supports both *top* and *left* navigation styles.



NavigationView supports both top and left navigation pane or menu

Is this the right control?

NavigationView is an adaptive navigation control that works well for:

- Providing a consistent navigational experience throughout your app.
- Preserving screen real estate on smaller windows.
- Organizing access to many navigation categories.

For other navigation patterns, see Navigation design basics.

Create a navigation view

✔ **Important APIs:** NavigationView class

Open the WinUI 3 Gallery app and see the NavigationView in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

This example shows how to create a simple navigation view in XAML.

XAML

```
<NavigationView>
    <NavigationView.MenuItems>
        <NavigationViewItem Content="Nav Item A"/>
        <NavigationViewItem Content="Nav Item B"/>
        <NavigationViewItem Content="Nav Item C"/>
    </NavigationView.MenuItems>

    <Frame x:Name="ContentFrame"/>
</NavigationView>
```

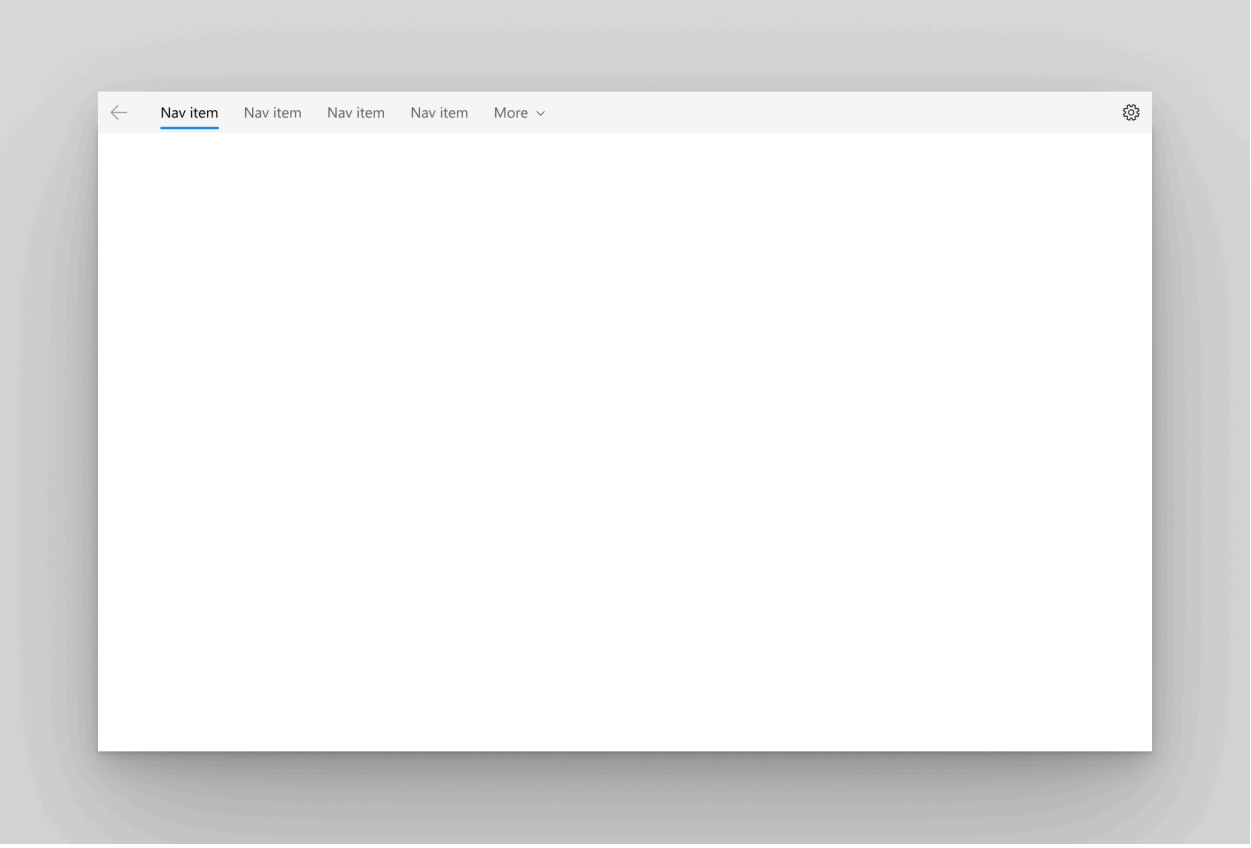
Display modes

You can use the PaneDisplayMode property to configure different navigation styles, or display modes, for the NavigationView.

Top

The pane is positioned above the content.

`PaneDisplayMode="Top"`



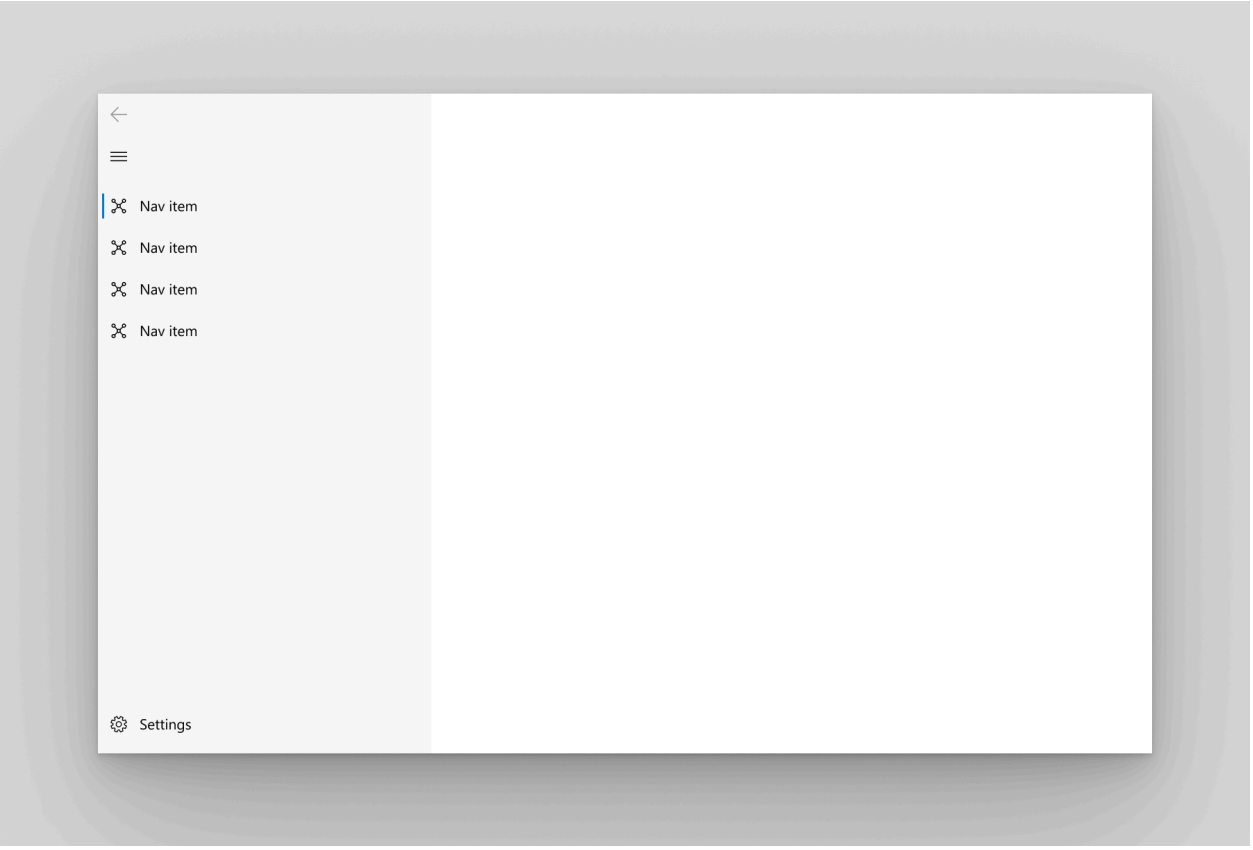
We recommend *top* navigation when:

- You have 5 or fewer top-level navigation categories that are equally important, and any additional top-level navigation categories that end up in the dropdown overflow menu are considered less important.
- You need to show all navigation options on screen.
- You want more space for your app content.
- Icons cannot clearly describe your app's navigation categories.

Left

The pane is expanded and positioned to the left of the content.

`PaneDisplayMode="Left"`



We recommend *left* navigation when:

- You have 5-10 equally important top-level navigation categories.
- You want navigation categories to be very prominent, with less space for other app content.

LeftCompact

The pane shows only icons until opened and is positioned to the left of the content. When opened, the pane overlays the content.
`PaneDisplayMode="LeftCompact"`

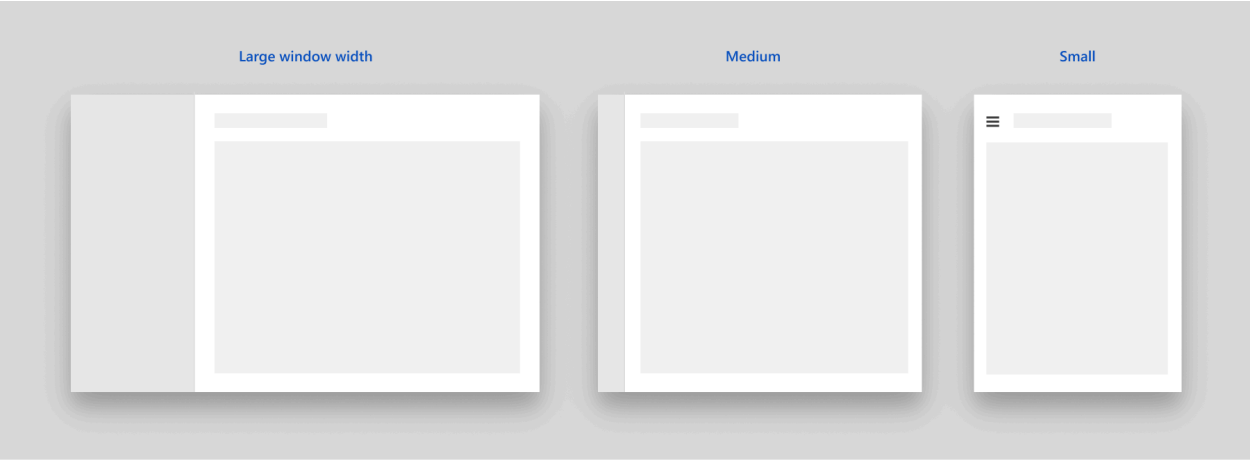
LeftMinimal

Only the menu button is shown until the pane is opened. When opened, the pane overlays the left side of the content.

`PaneDisplayMode="LeftMinimal"`

Auto

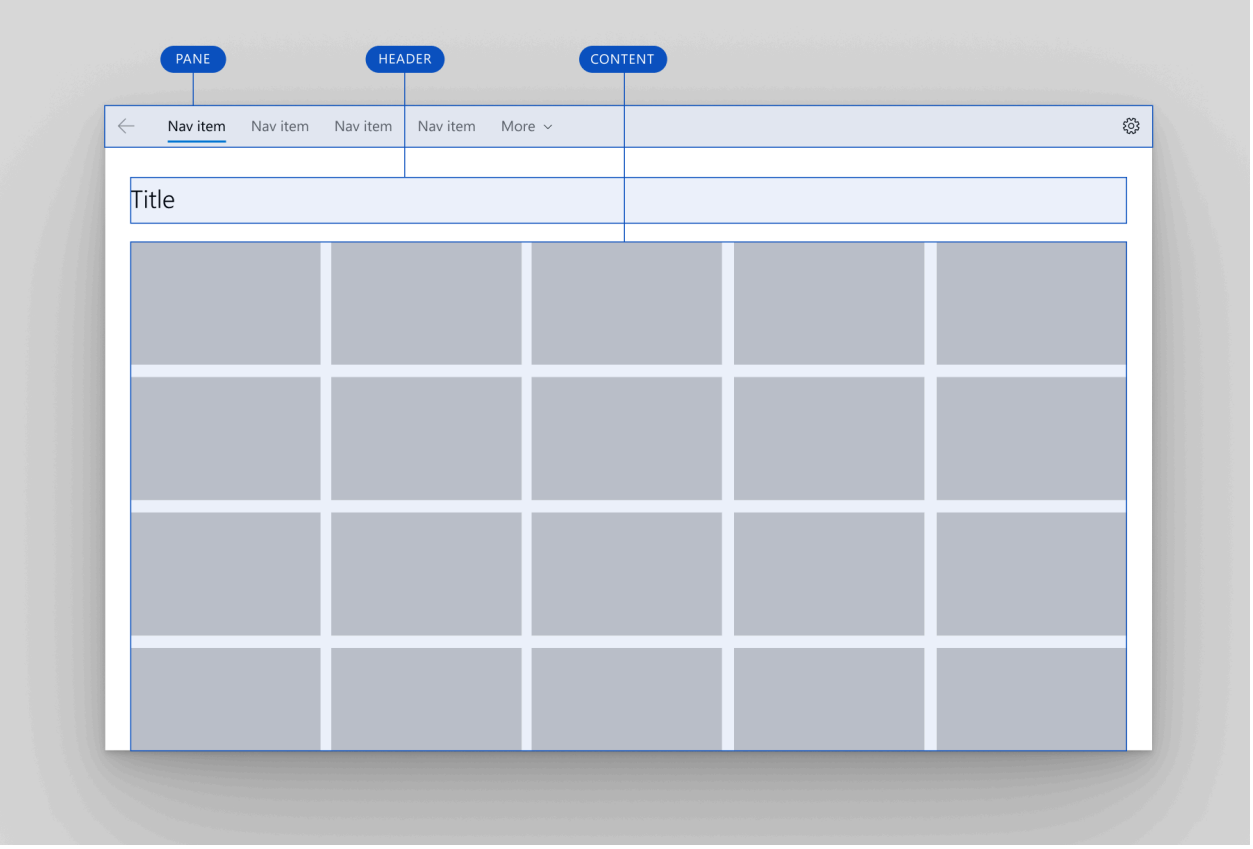
By default, PaneDisplayMode is set to `Auto`. In `Auto` mode, the NavigationView adapts between `LeftMinimal` when the window is narrow, to `LeftCompact`, and then `Left` as the window gets wider. For more info, see the adaptive behavior section.



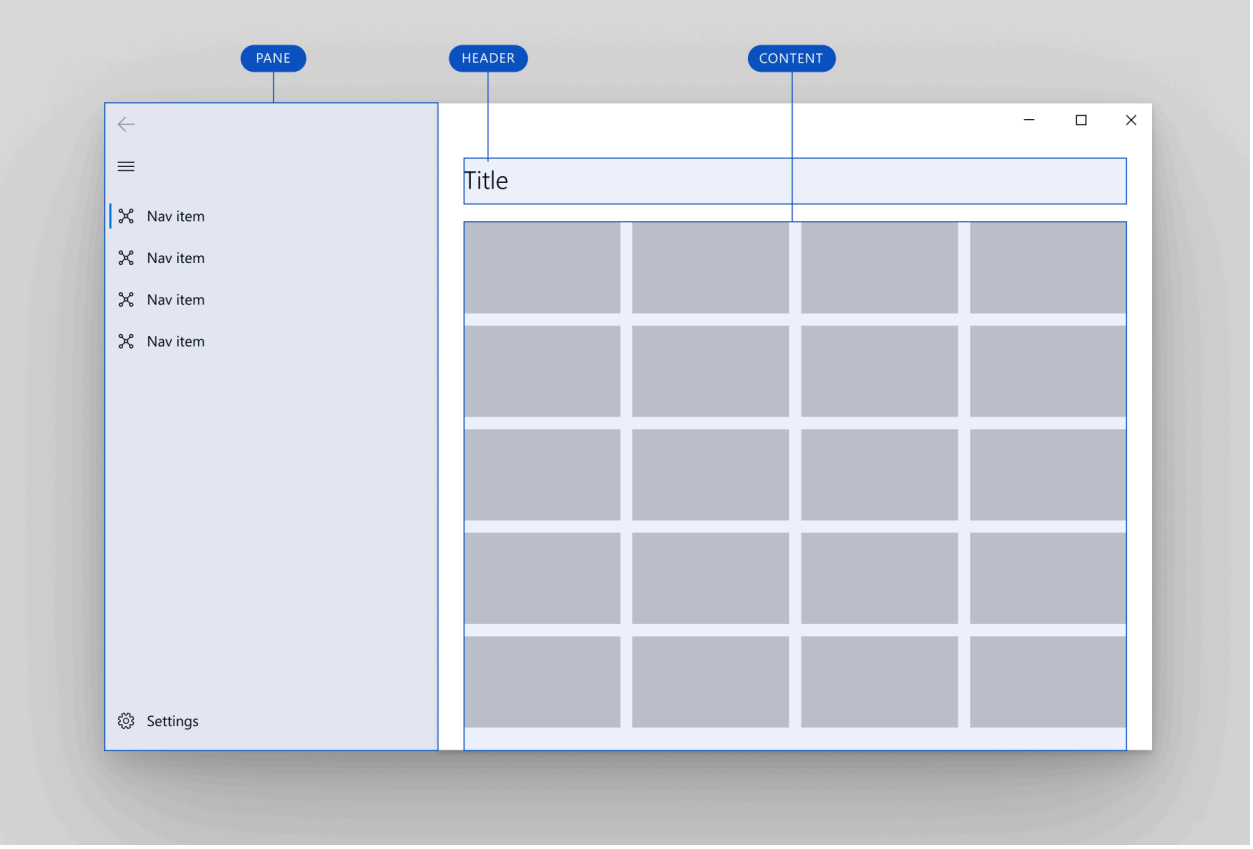
NavigationView default adaptive behavior

Anatomy

These images show the layout of the pane, header, and content areas of the control when configured for *top* or *left* navigation.



Top navigation layout



Left navigation layout

Pane

You can use the PaneDisplayMode property to position the pane above the content or to the left of the content.

The NavigationView pane can contain:

- NavigationViewItem objects. Navigation items for navigating to specific pages.
- NavigationViewItemSeparator objects. Separators for grouping navigation items. Set the Opacity property to 0 to render the separator as space.
- NavigationViewItemHeader objects. Headers for labeling groups of items.
- An optional AutoSuggestBox control to allow for app-level search. Assign the control to the NavigationView.AutoSuggestBox property.
- An optional entry point for app settings. To hide the settings item, set the IsSettingsVisible property to `false`.

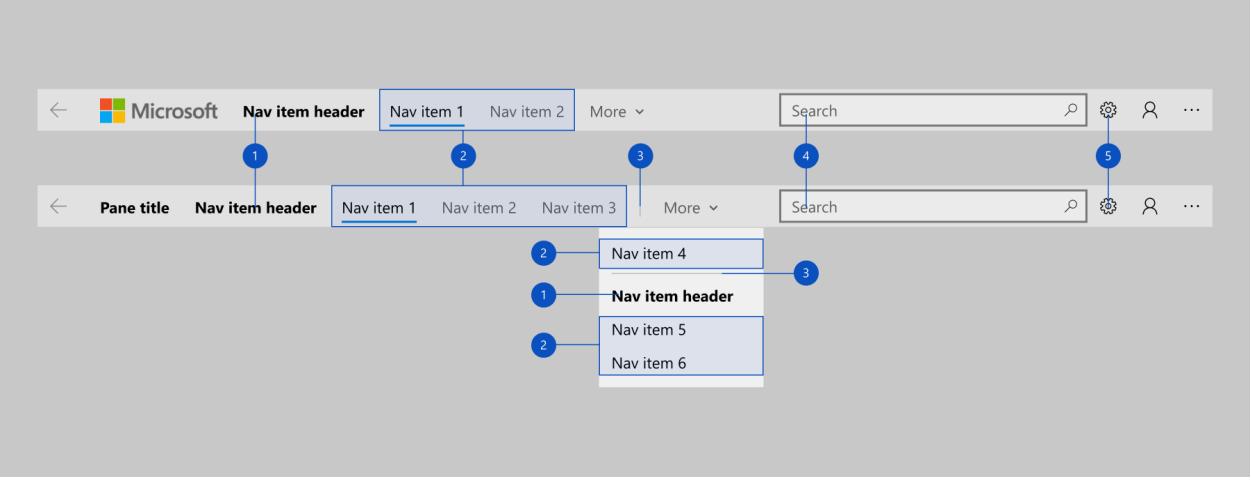
The left pane also contains:

- A menu button to toggle the pane opened and closed. On larger app windows when the pane is open, you may choose to hide this button using the IsPaneToggleButtonVisible property.

The NavigationView has a back button that is placed in the top left-hand corner of the pane. However, it does not automatically handle backwards navigation and add content to the back stack. To enable backwards navigation, see the backwards navigation section.

Here is the detailed pane anatomy for the top and left pane positions.

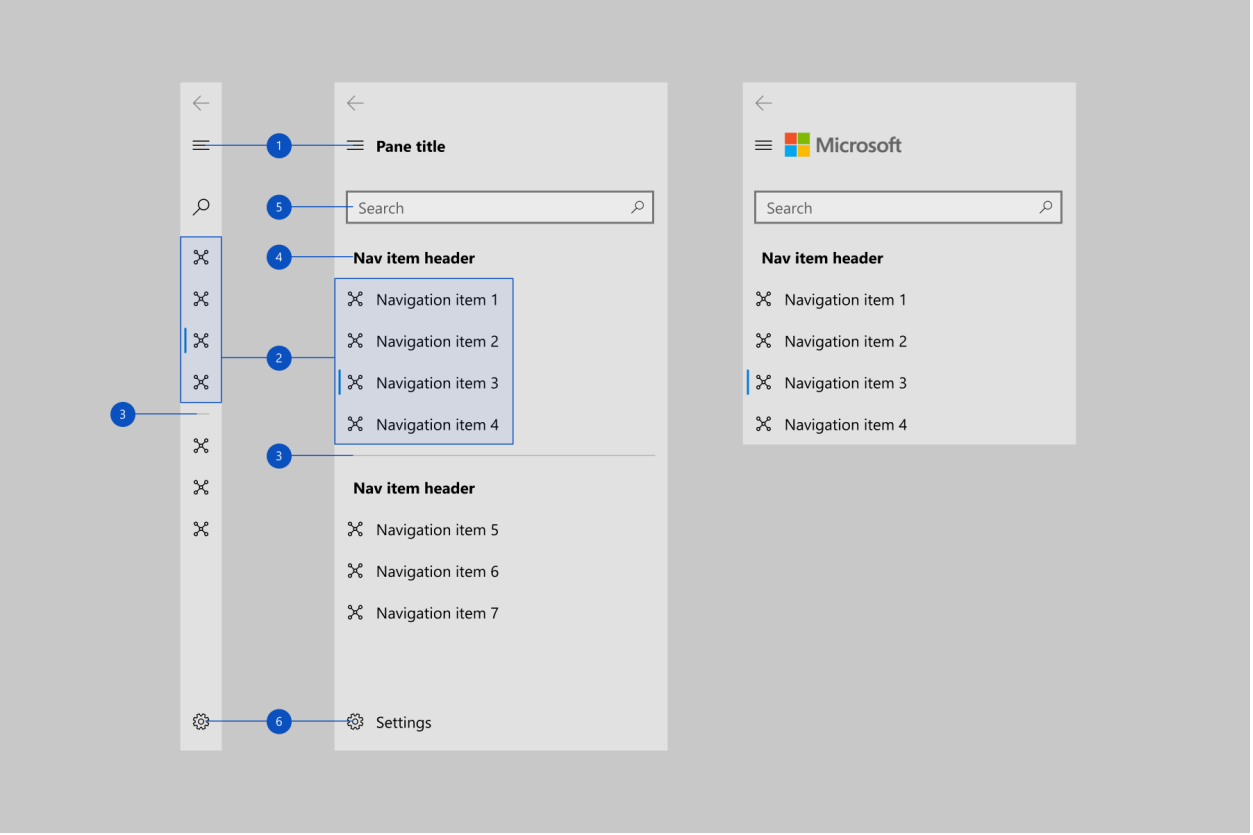
Top navigation pane



1. Headers
2. Navigation items
3. Separators

4. AutoSuggestBox (optional)
5. Settings button (optional)

Left navigation pane



1. Menu button
2. Navigation items
3. Separators
4. Headers
5. AutoSuggestBox (optional)
6. Settings button (optional)

Footer menu items

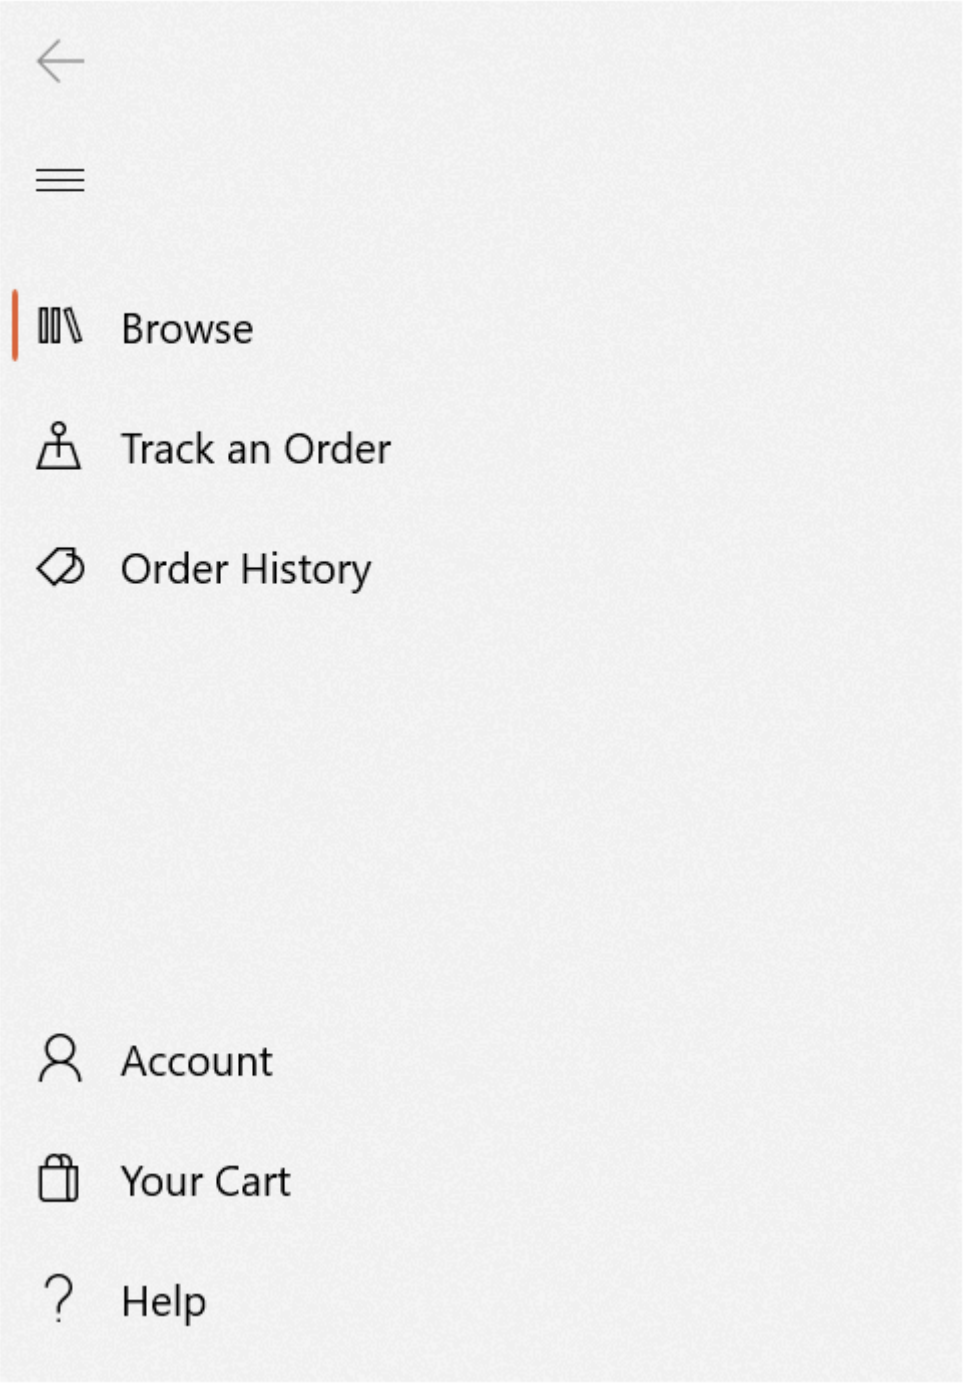
You can use FooterMenuItems to place navigation items at the end of the navigation pane, contrasted with the MenuItems property which places items at the start of the pane.

FooterMenuItems will be displayed before the `Settings` item by default. The `Settings` item can still be toggled using the IsSettingsVisible property.

Only Navigation items should be placed in FooterMenuItems - any other content that needs to align to the footer of the pane should be placed in PaneFooter.

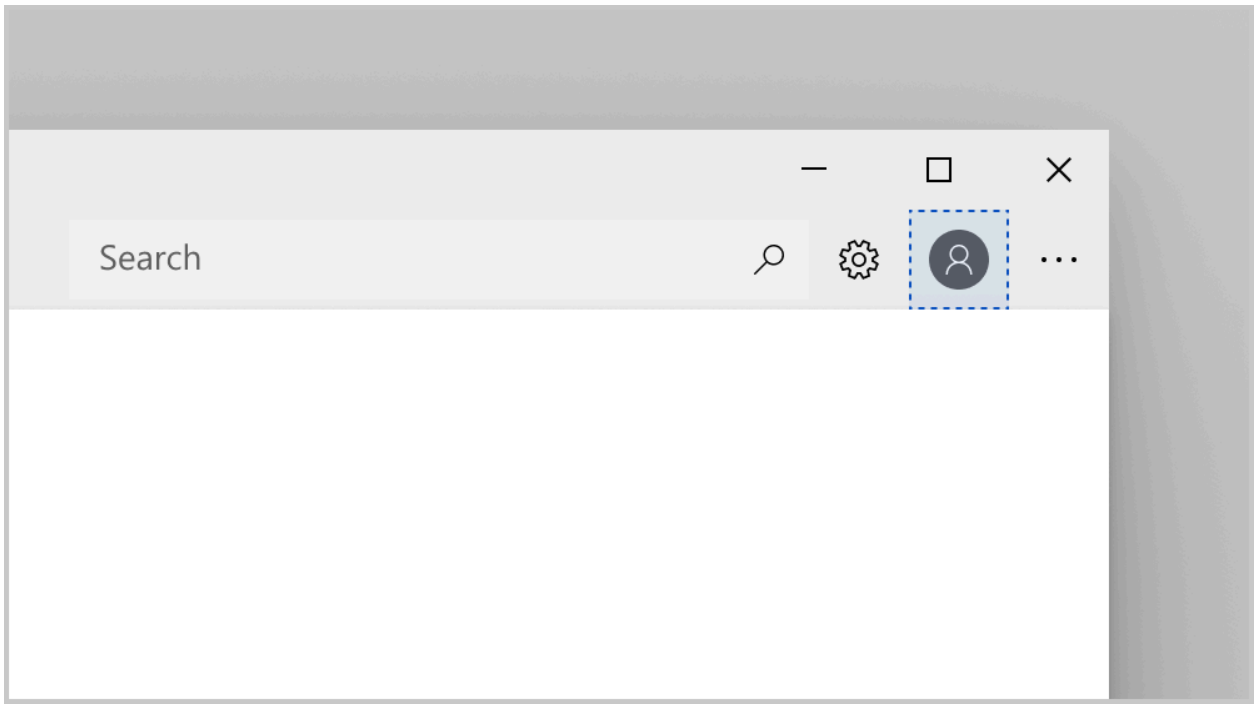
For an example of how to add FooterMenuItems to your NavigationView, see the FooterMenuItems class.

The image below shows a NavigationView with **Account**, **Your Cart**, and **Help** navigation items in the footer menu.

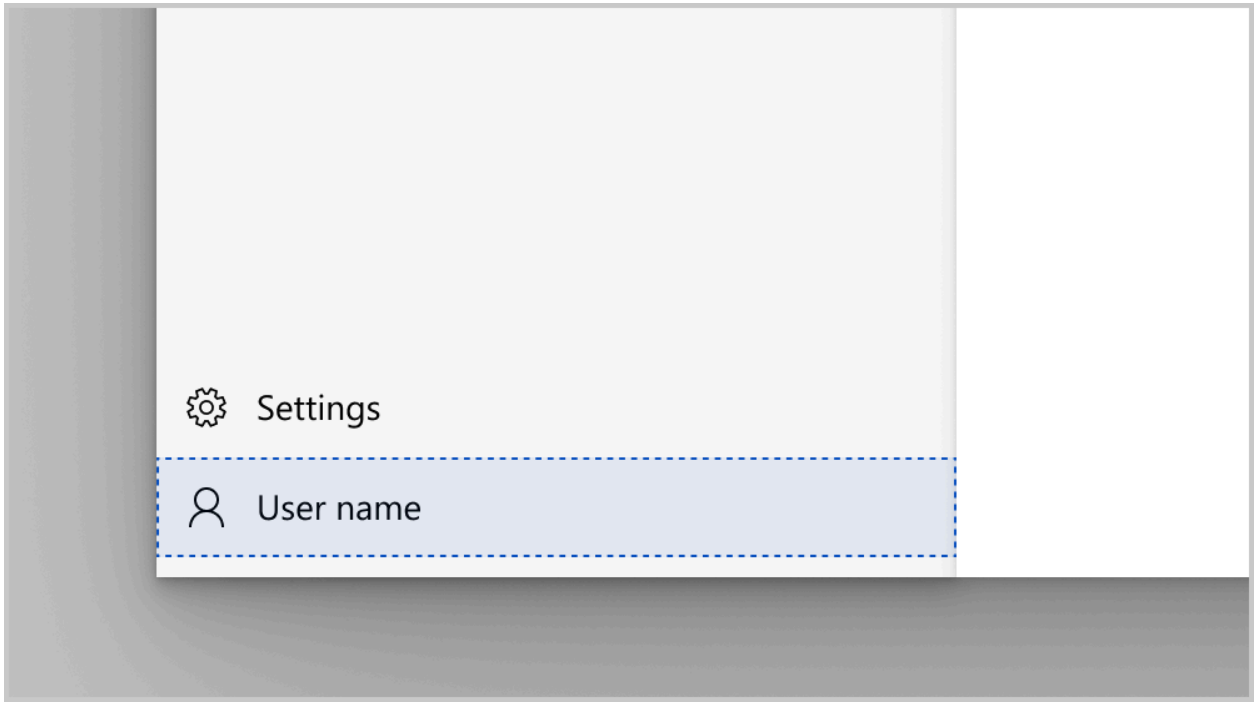


Pane footer

You can place free-form content in the pane's footer by adding it to the PaneFooter property.



Top pane footer



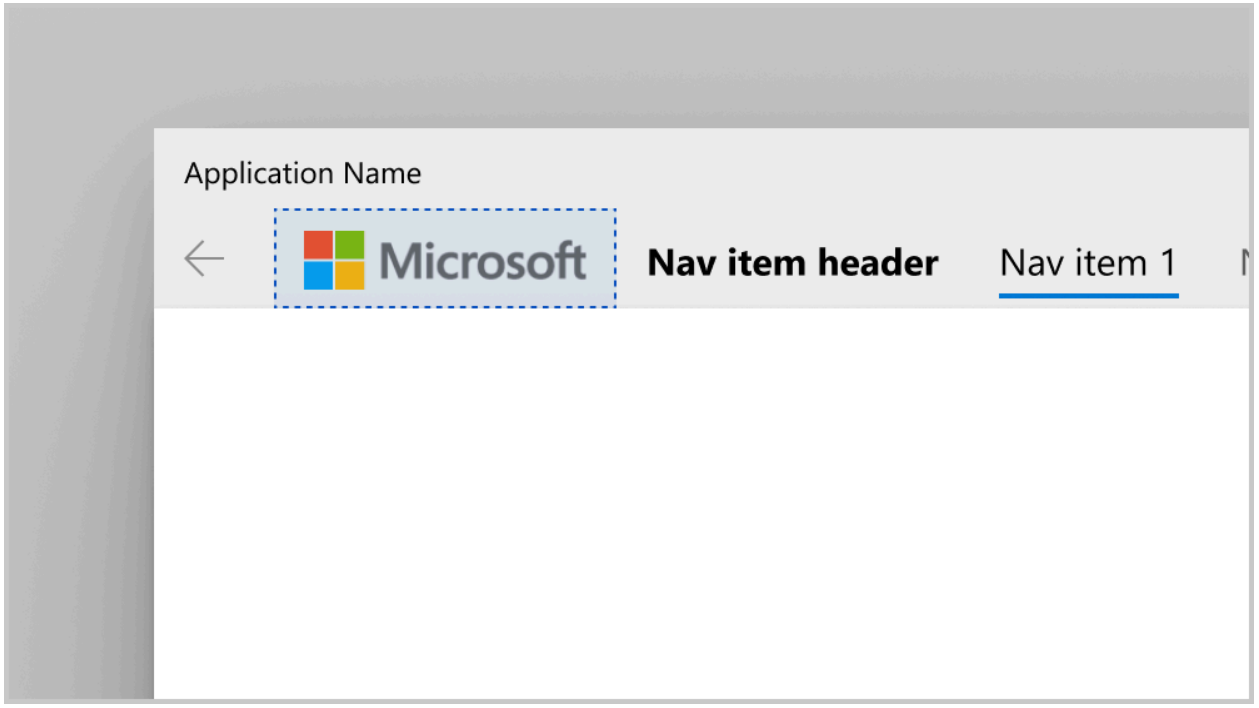
Left pane footer

Pane title and header

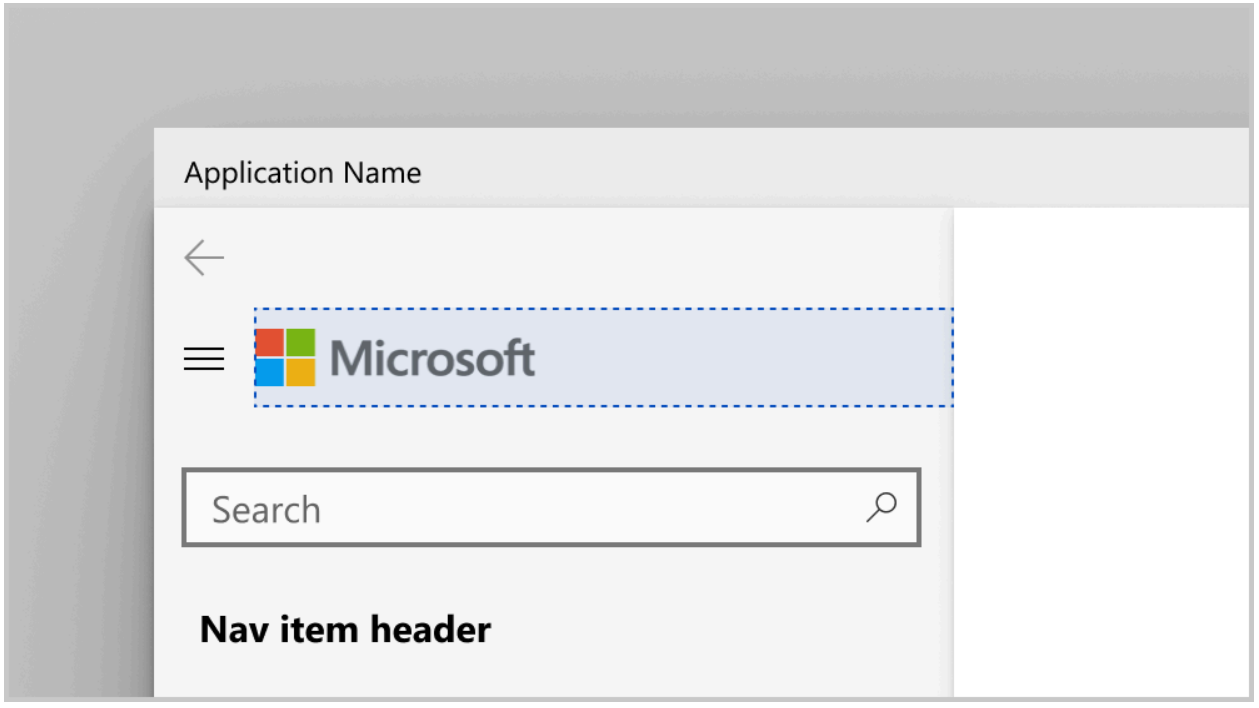
You can place text content in the pane header area by setting the PaneTitle property. It takes a string and shows the text next to the menu button.

To add non-text content, such as an image or logo, you can place any element in the pane's header by adding it to the PaneHeader property.

If both PaneTitle and PaneHeader are set, the content is stacked horizontally next to the menu button, with the PaneTitle closest to the menu button.



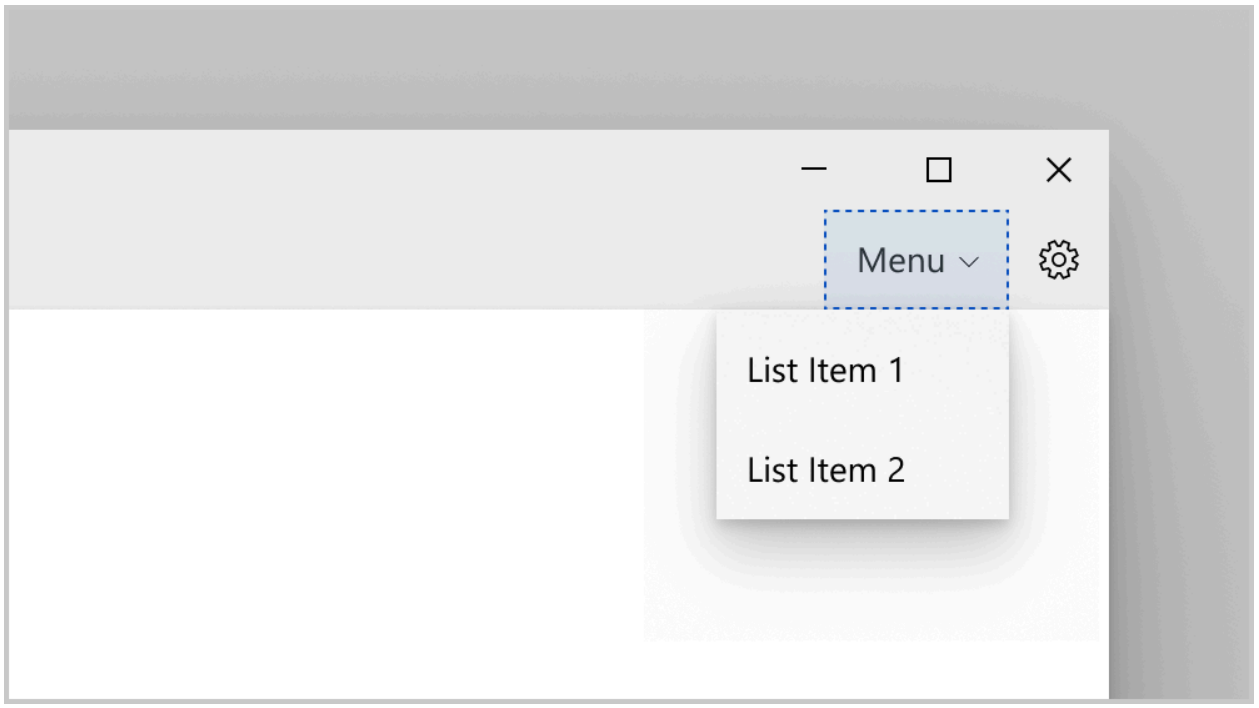
Top pane header



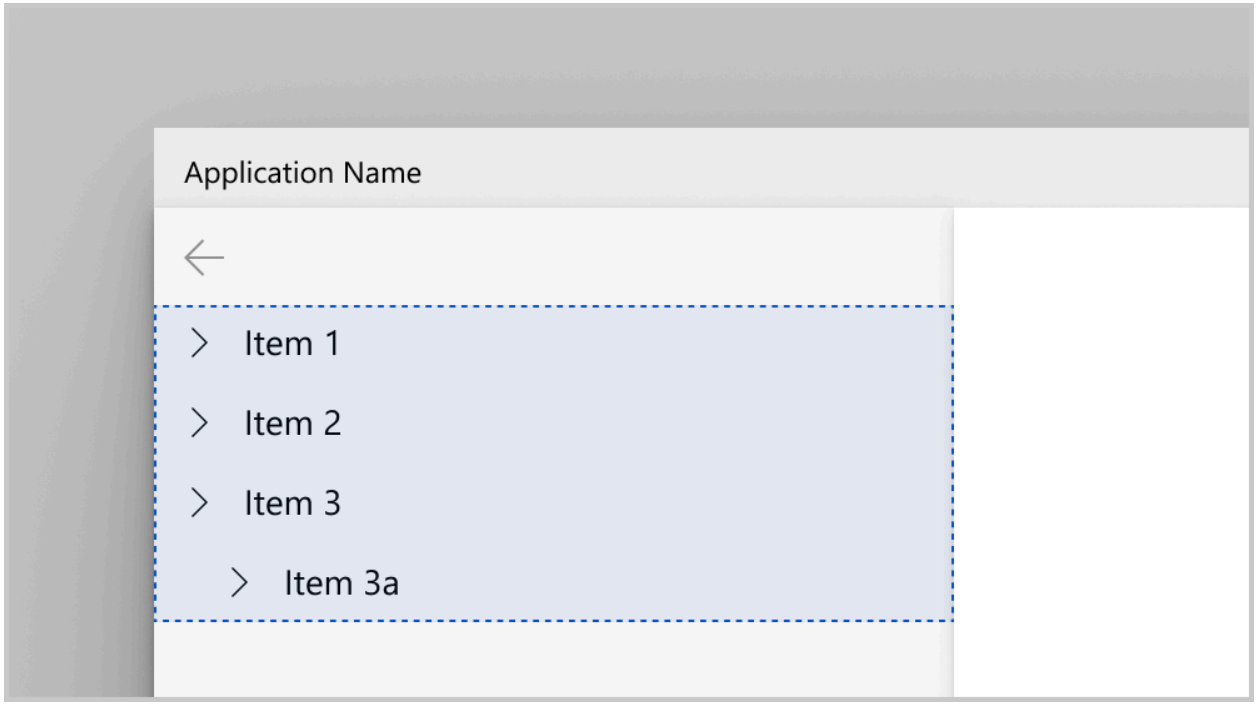
Left pane header

Pane content

You can place free-form content in the pane by adding it to the PaneCustomContent property.



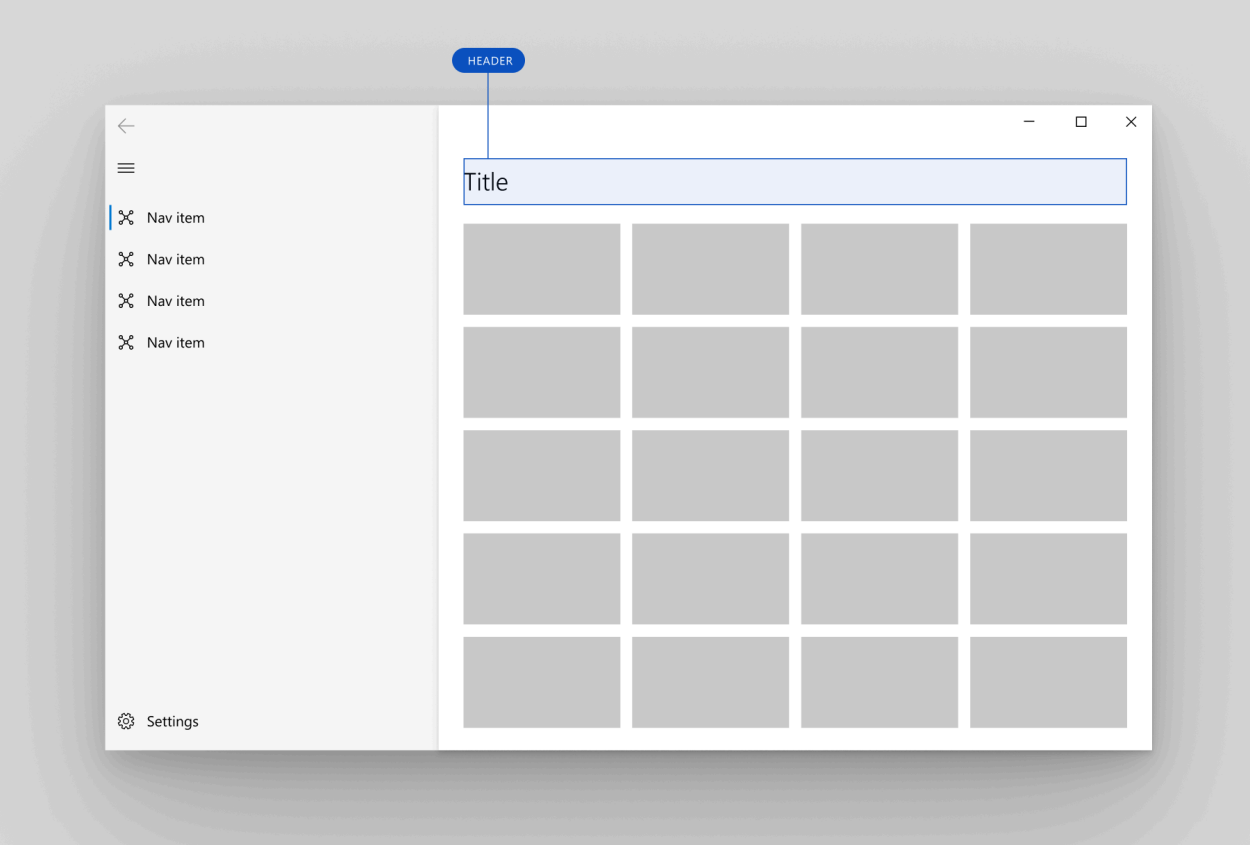
Top pane custom content



Left pane custom content

Header

You can add a page title by setting the Header property.

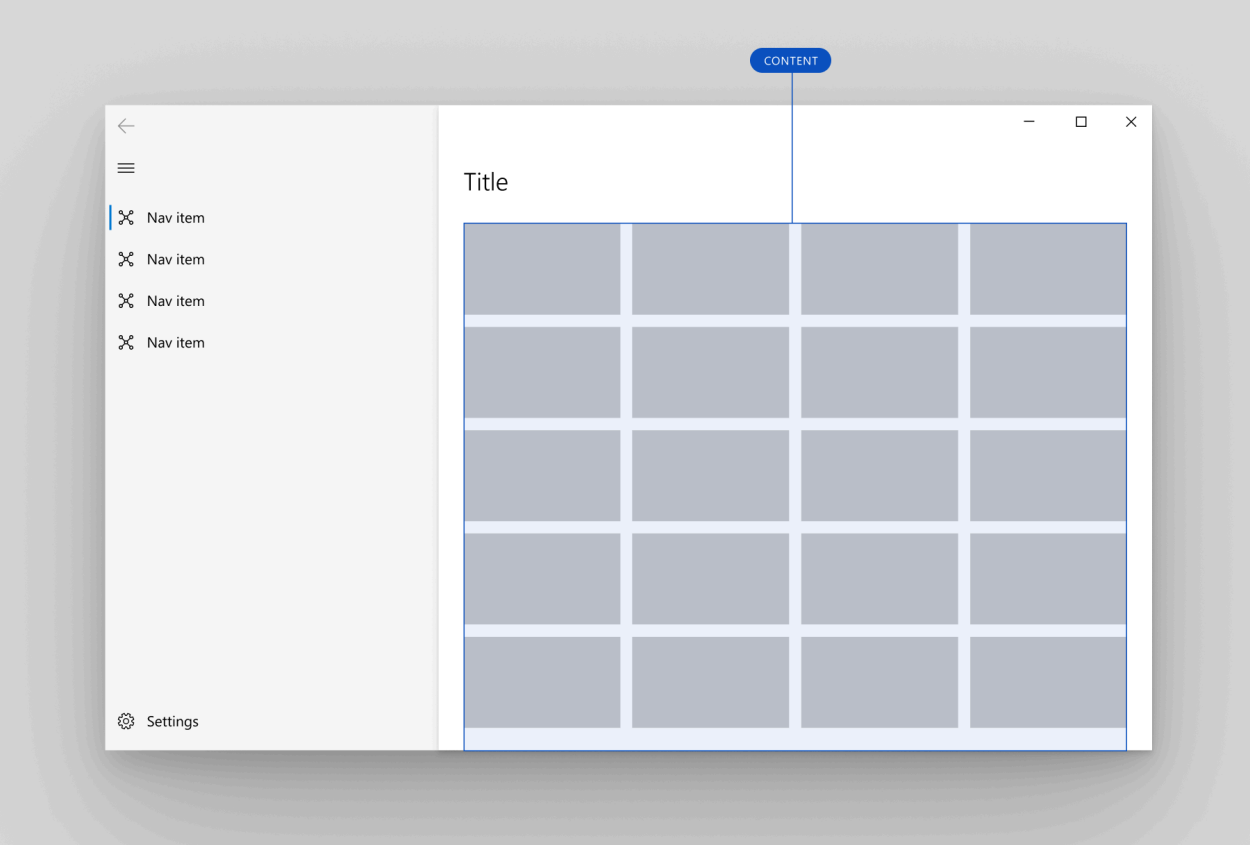


NavigationView header

The header area is vertically aligned with the navigation button in the left pane position, and lies below the pane in the top pane position. It has a fixed height of 52 px. Its purpose is to hold the page title of the selected navigation category. The header is docked to the top of the page and acts as a scroll clipping point for the content area.

The header is visible any time the NavigationView is in `Minimal` display mode. You may choose to hide the header in other modes, which are used on larger window widths. To hide the header, set the AlwaysShowHeader property to `false`.

Content



NavigationView content

The content area is where most of the information for the selected navigation category is displayed.

We recommend 12px margins for your content area when NavigationView is in `Minimal` mode and 24px margins otherwise.

Adaptive behavior

By default, the NavigationView automatically changes its display mode based on the amount of screen space available to it. The CompactModeThresholdWidth and ExpandedModeThresholdWidth properties specify the breakpoints at which the display mode changes. You can modify these values to customize the adaptive display mode behavior.

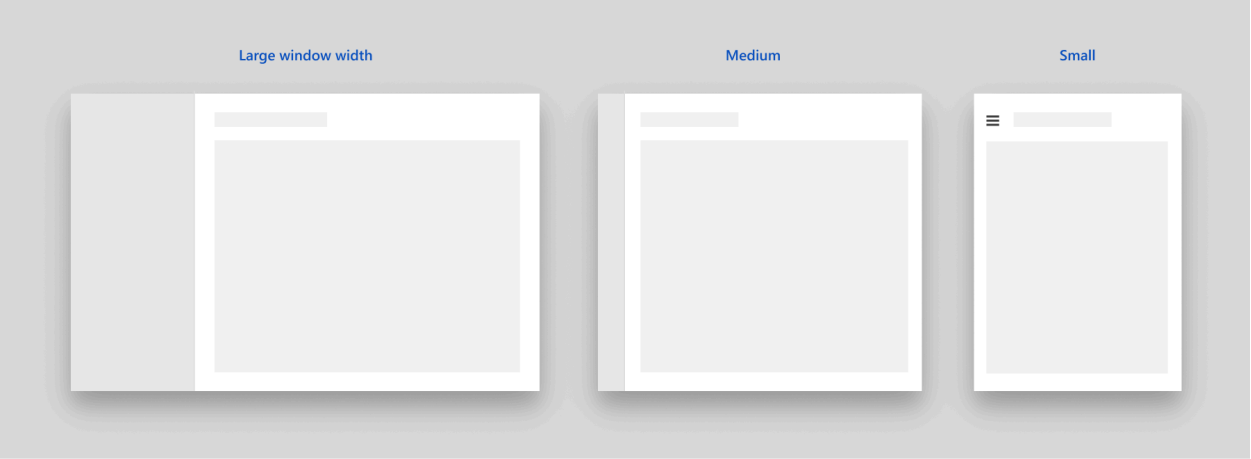
Default

When PaneDisplayMode is set to its default value of `Auto`, the adaptive behavior is to show:

- An expanded left pane on large window widths (1008px or greater).
- A left, icon-only, nav pane (`LeftCompact`) on medium window widths (641px to 1007px).

- Only a menu button (`LeftMinimal`) on small window widths (640px or less).

For more information about window sizes for adaptive behavior, see Screen sizes and breakpoints.



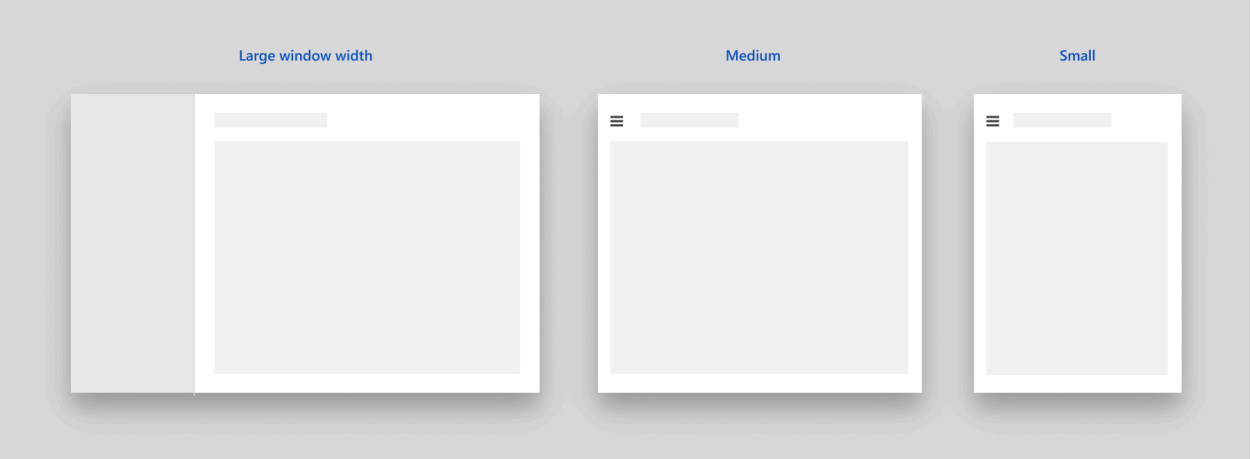
NavigationView default adaptive behavior

Minimal

A second common adaptive pattern is to use an expanded left pane on large window widths, and only a menu button on both medium and small window widths.

We recommend this when:

- You want more space for app content on smaller window widths.
- Your navigation categories cannot be clearly represented with icons.



NavigationView "minimal" adaptive behavior

To configure this behavior, set CompactModeThresholdWidth to the width at which you want the pane to collapse. Here, it's changed from the default of 640 to 1007. You should also set ExpandedModeThresholdWidth to ensure the values don't conflict.

XAML

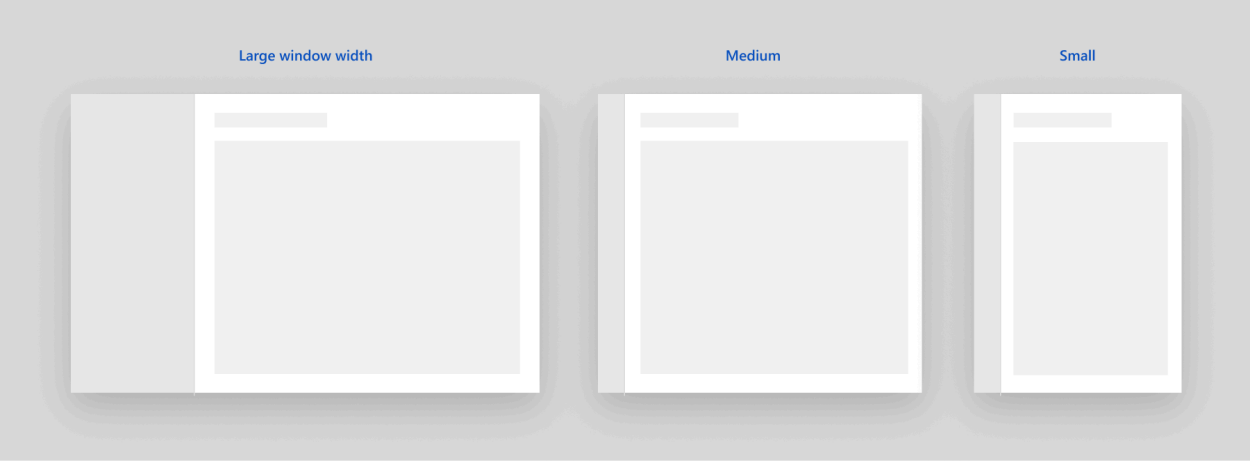
```
<NavigationView CompactModeThresholdWidth="1007"
ExpandedModeThresholdWidth="1007"/>
```

Compact

A third common adaptive pattern is to use an expanded left pane on large window widths, and a LeftCompact, icon-only, nav pane on both medium and small window widths.

We recommend this when:

- It is important to always show all navigation options on screen.
- Your navigation categories can be clearly represented with icons.



NavigationView "compact" adaptive behavior

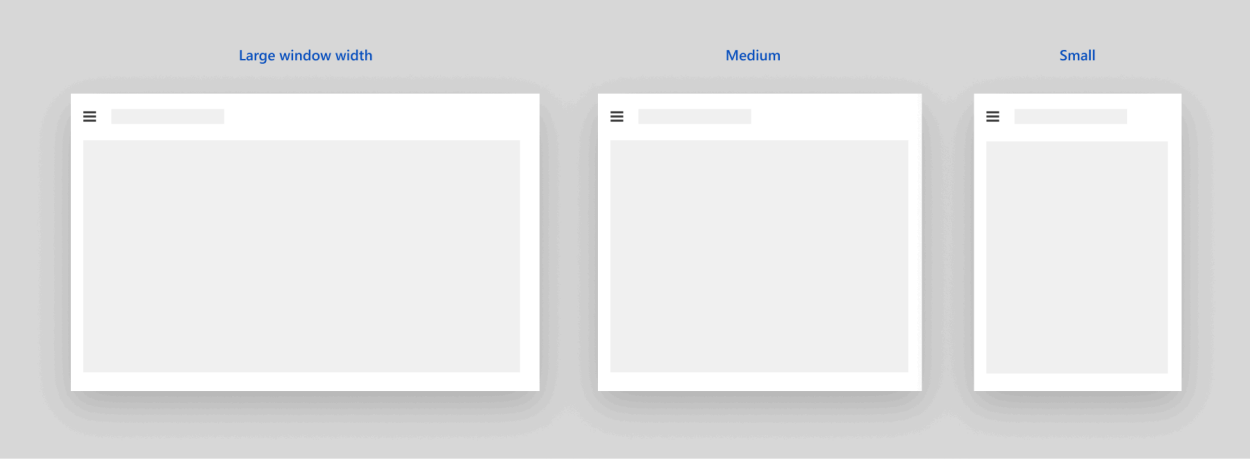
To configure this behavior, set CompactModeThresholdWidth to 0.

XAML

```
<NavigationView CompactModeThresholdWidth="0"/>
```

No adaptive behavior

To disable the automatic adaptive behavior, set PaneDisplayMode to a value other than `Auto`. Here, it's set to LeftMinimal, so only the menu button is shown regardless of the window width.



NavigationView with PaneDisplayMode set to LeftMinimal

XAML

```
<NavigationView PaneDisplayMode="LeftMinimal" />
```

As described previously in the *Display modes* section, you can set the pane to be always on top, always expanded, always compact, or always minimal. You can also manage the display modes yourself in your app code. An example of this is shown in the next section.

Top to left navigation

When you use top navigation in your app, navigation items collapse into an overflow menu as the window width decreases. When your app window is narrow, it can provide a better user experience to switch the PaneDisplayMode from `Top` to `LeftMinimal` navigation, rather than letting all the items collapse into the overflow menu.

We recommend using top navigation on large window sizes and left navigation on small window sizes when:

- You have a set of equally important top-level navigation categories to be displayed together, such that if one category in this set doesn't fit on screen, you collapse to left navigation to give them equal importance.
- You wish to preserve as much content space as possible in small window sizes.

This example shows how to use a VisualStateManager and AdaptiveTrigger.MinWindowWidth property to switch between `Top` and `LeftMinimal` navigation.

XAML

```
<Grid>
    <NavigationView x:Name="NavigationViewControl" >
        <NavigationView.MenuItems>
            <NavigationViewItem Content="A" x:Name="A" />
            <NavigationViewItem Content="B" x:Name="B" />
            <NavigationViewItem Content="C" x:Name="C" />
        </NavigationView.MenuItems>
    </NavigationView>

    <VisualStateManager.VisualStateGroups>
        <VisualStateGroup>
            <VisualState>
                <VisualState.StateTriggers>
                    <AdaptiveTrigger
                        MinWindowWidth="{x:Bind
NavigationViewControl.CompactModeThresholdWidth}" />
                </VisualState.StateTriggers>

                <VisualState.Setters>
                    <Setter Target="NavigationViewControl.PaneDisplayMode"
Value="Top"/>
                </VisualState.Setters>
            </VisualState>
        </VisualStateGroup>
    </VisualStateManager.VisualStateGroups>
</Grid>
```

Tip

When you use AdaptiveTrigger.MinWindowWidth, the visual state is triggered when the window is wider than the specified minimum width. This means the default XAML defines the narrow window, and the VisualState defines the modifications that are applied when the window gets wider. The default PaneDisplayMode for the NavigationView is Auto, so when the window width is less than or equal to

`CompactModeThresholdWidth`, `LeftMinimal` navigation is used. When the window gets wider, the VisualState overrides the default, and `Top` navigation is used.

Navigation

The NavigationView doesn't perform any navigation tasks automatically. When the user taps on a navigation item, the NavigationView shows that item as selected and raises an ItemInvoked event. If the tap results in a new item being selected, a SelectionChanged event is also raised.

You can handle either event to perform tasks related to the requested navigation. Which one you should handle depends on the behavior you want for your app. Typically, you navigate to the requested page and update the NavigationView header in response to these events.

- ItemInvoked is raised any time the user taps a navigation item, even if it's already selected. (The item can also be invoked with an equivalent action using mouse, keyboard, or other input. For more info, see Input and interactions.) If you navigate in the ItemInvoked handler, by default, the page will be reloaded, and a duplicate entry is added to the navigation stack. If you navigate when an item is invoked, you should disallow reloading the page, or ensure that a duplicate entry is not created in the navigation backstack when the page is reloaded. (See code examples.)
- SelectionChanged can be raised by a user invoking an item that isn't currently selected, or by programmatically changing the selected item. If the selection change occurs because a user invoked an item, the ItemInvoked event occurs first. If the selection change is programmatic, ItemInvoked is not raised.

All navigation items are part of the same selection model, whether they are a part of MenuItems or FooterMenuItems. Only one navigation item can be selected at a time.

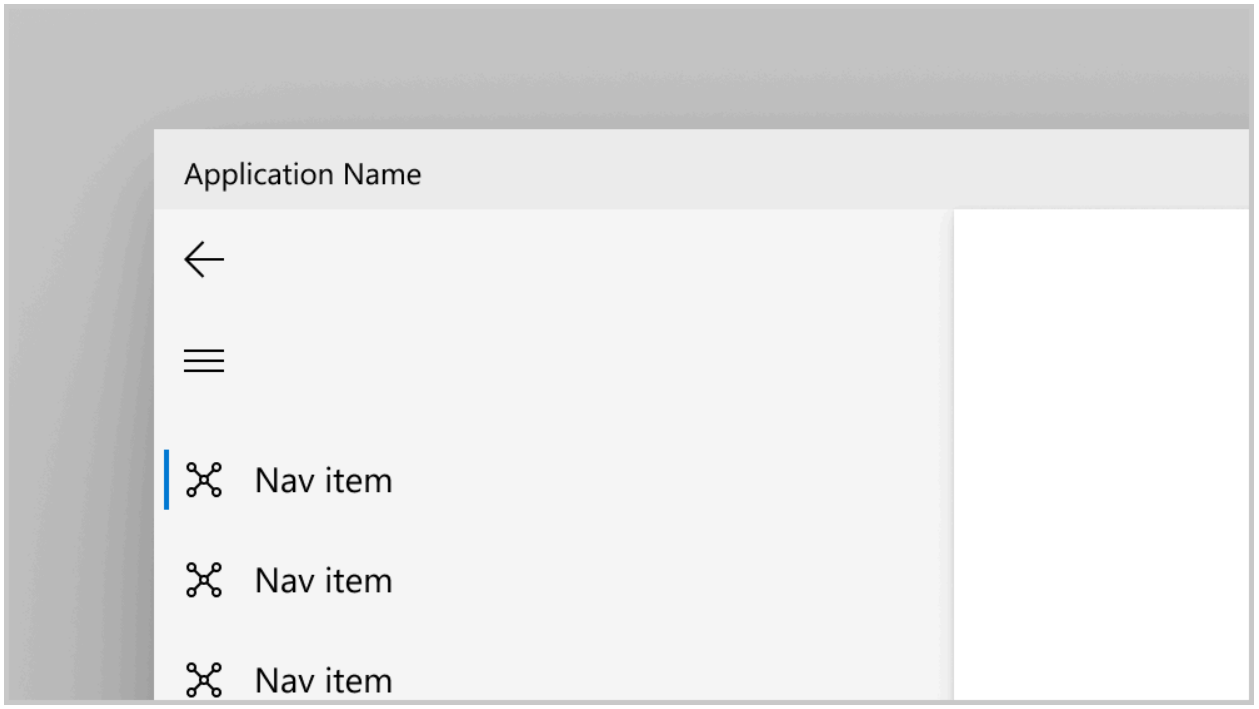
Backwards navigation

NavigationView has a built-in back button; but, as with forward navigation, it doesn't perform backwards navigation automatically. When the user taps the back button, the BackRequested event is raised. You handle this event to perform backwards navigation. For more info and code examples, see Navigation history and backwards navigation.

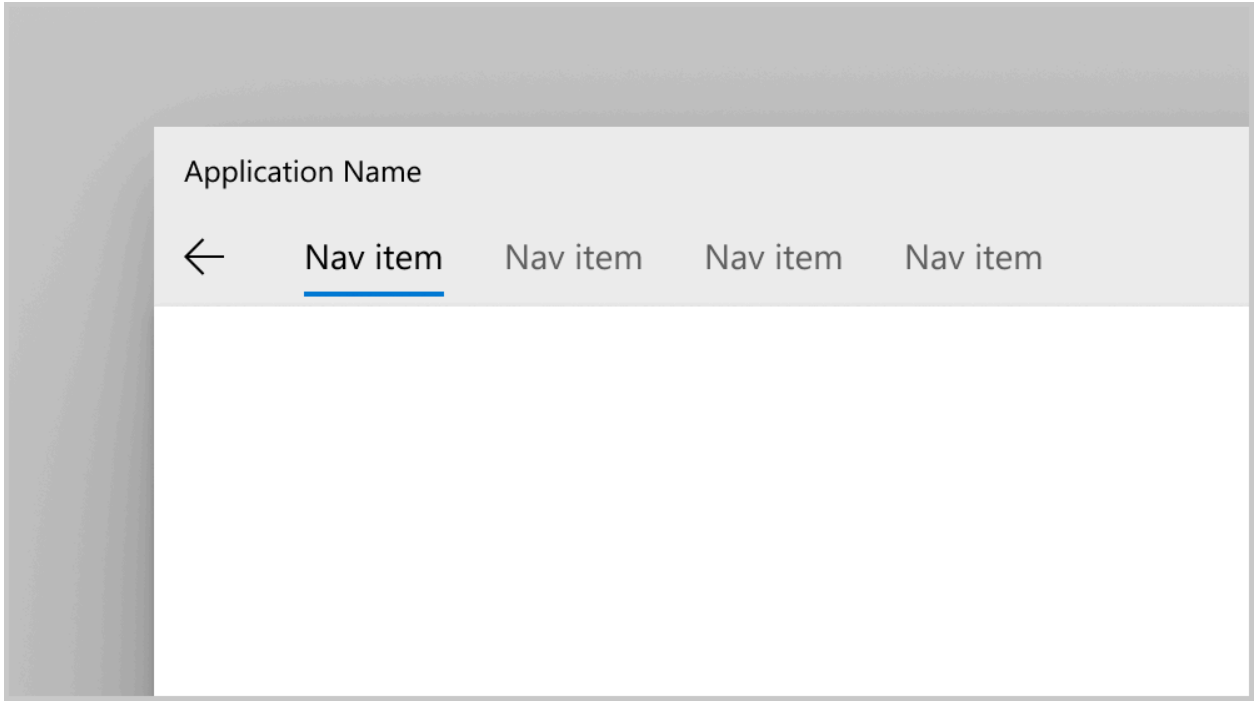
In `Minimal` or `Compact` mode, the NavigationView `Pane` is open as a flyout. In this case, clicking the back button will close the `Pane` and raise the PaneClosing event instead.

You can hide or disable the back button by setting these properties:

- IsBackButtonVisible: use to show and hide the back button. This property takes a value of the NavigationViewBackButtonVisible enumeration, and is set to `Auto` by default. When the button is collapsed, no space is reserved for it in the layout.
- IsBackEnabled: use to enable or disable the back button. You can data bind this property to the CanGoBack property of your navigation frame. BackRequested is not raised if `IsBackEnabled` is `false`.



The back button in the left navigation pane



The back button in the top navigation pane

Code example

This example shows how you can use NavigationView with both a top navigation pane on large window sizes and a left navigation pane on small window sizes. It can be adapted to left-only navigation by removing the *top* navigation settings in the VisualStateManager.

The example demonstrates a common way to set up navigation data that will work for many scenarios. In this example, you first store (in the tag of the NavigationViewItem) the full type name of the page to which you want to navigate. In the event handler, you unbox that value, turn it into a Type(C#) or **Windows::UI::Xaml::Interop::TypeName**(C++/WinRT) object, and use that to navigate to the destination page. This lets you create unit tests to confirm that the values inside your tags are of a valid type. (Also see Boxing and unboxing values to IInspectable with C++/WinRT). It also demonstrates how to implement backwards navigation with NavigationView's back button.

This code assumes that your app contains pages with the following names to navigate to: *HomePage*, *AppsPage*, *GamesPage*, *MusicPage*, *MyContentPage*, and *SettingsPage*. Code for these pages is not shown.

XAML

```
<Page ... >
 <Grid>
     <NavigationView x:Name="NavView"
                     Loaded="NavView_Loaded"
                     ItemInvoked="NavView_ItemInvoked"
                     BackRequested="NavView_BackRequested">
         <NavigationView.MenuItems>
             <NavigationViewItem Tag="NavigationViewDemo.HomePage"
Icon="Home" Content="Home"/>
             <NavigationViewItemSeparator/>
             <NavigationViewItemHeader x:Name="MainPagesHeader"
                                       Content="Main pages"/>
             <NavigationViewItem Tag="NavigationViewDemo.AppsPage"
Content="Apps">
                 <NavigationViewItem.Icon>
                     <FontIcon Glyph="&#xEB3C;"/>
                 </NavigationViewItem.Icon>
             </NavigationViewItem>
             <NavigationViewItem Tag="NavigationViewDemo.GamesPage"
Content="Games">
                 <NavigationViewItem.Icon>
                     <FontIcon Glyph="&#xE7FC;"/>
                 </NavigationViewItem.Icon>
             </NavigationViewItem>
             <NavigationViewItem Tag="NavigationViewDemo.MusicPage"
```

```
Icon="Audio" Content="Music"/>
        </NavigationView.MenuItems>

        <NavigationView.AutoSuggestBox>
            <!-- See AutoSuggestBox documentation for
             more info about how to implement search. -->
            <AutoSuggestBox x:Name="NavViewSearchBox" QueryIcon="Find"/>
        </NavigationView.AutoSuggestBox>

        <ScrollViewer>
            <Frame x:Name="ContentFrame" IsTabStop="True"
               NavigationFailed="ContentFrame_NavigationFailed"/>
        </ScrollViewer>
    </NavigationView>

                    .OfType<NavigationViewItem>()
                    .First(i =>
i.Tag.Equals(ContentFrame.SourcePageType.FullName.ToString()));

        NavView.Header =
            ((NavigationViewItem)NavView.SelectedItem)?.Content?.ToString();

    }
}
```

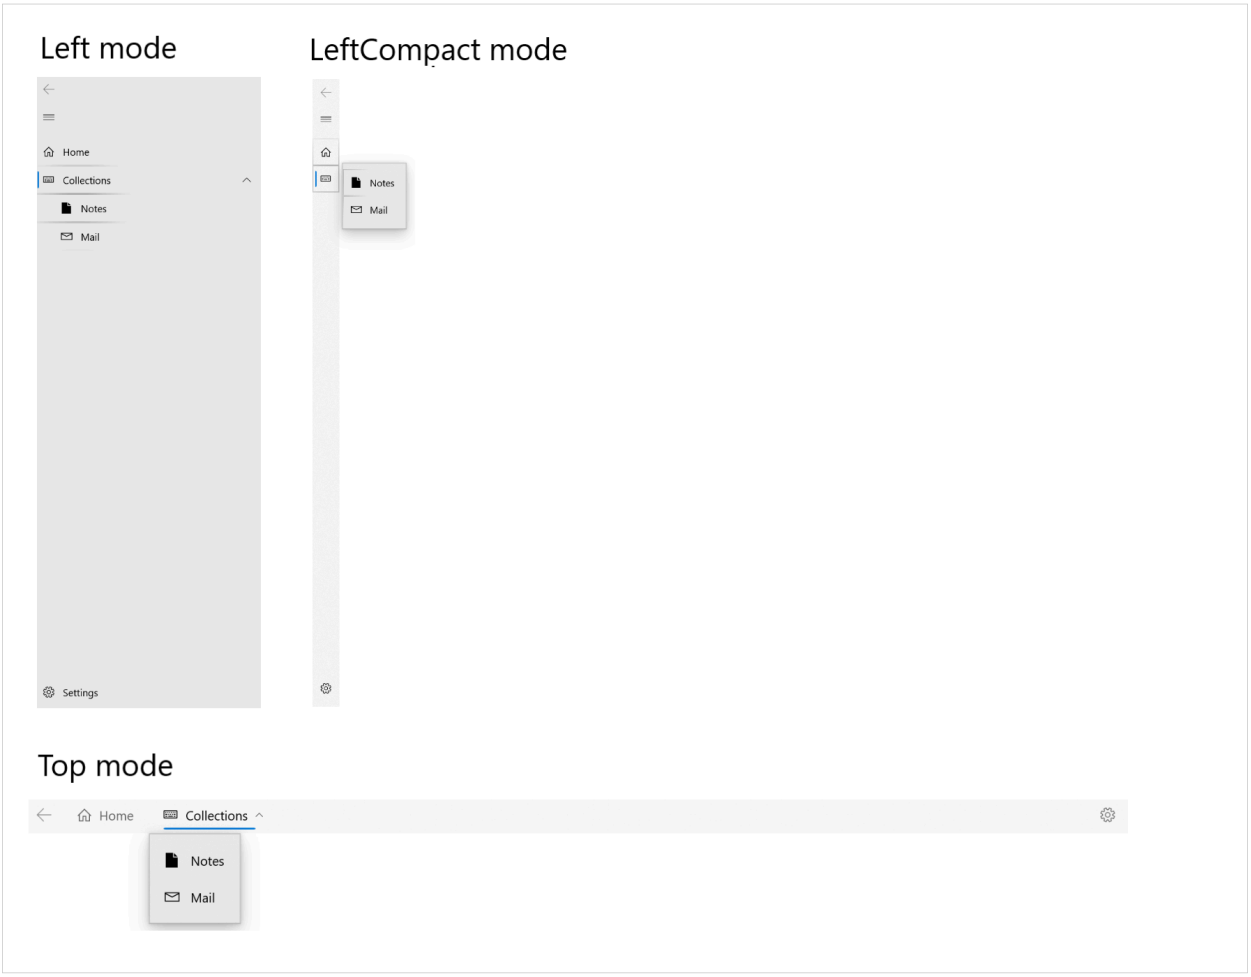
Hierarchical navigation

Some apps may have a more complex hierarchical structure that requires more than just a flat list of navigation items. You may want to use top-level navigation items to display categories of pages, with children items displaying specific pages. It is also useful if you have hub-style pages that only link to other pages. For these kinds of cases, you should create a hierarchical NavigationView.

To show a hierarchical list of nested navigation items in the pane, use either the MenuItems property or the MenuItemsSource property of **NavigationViewItem**. Each NavigationViewItem can contain other NavigationViewItems and organizing elements like item headers and separators. To show a hierarchical list when using `MenuItemsSource`, set the `ItemTemplate` to be a NavigationViewItem, and bind its `MenuItemsSource` property to the next level of the hierarchy.

Although NavigationViewItem can contain any number of nested levels, we recommend keeping your app's navigation hierarchy shallow. We believe two levels is ideal for usability and comprehension.

NavigationView shows hierarchy in `Top`, `Left`, and `LeftCompact` pane display modes. Here is what an expanded subtree looks like in each of the pane display modes:



Adding a hierarchy of items in markup

This example shows how to declare hierarchical app navigation in XAML markup.

XAML

```
<NavigationView>
    <NavigationView.MenuItems>
        <NavigationViewItem Content="Home" Icon="Home"
ToolTipService.ToolTip="Home"/>
        <NavigationViewItem Content="Collections" Icon="Keyboard"
ToolTipService.ToolTip="Collections">
            <NavigationViewItem.MenuItems>
                <NavigationViewItem Content="Notes" Icon="Page"
ToolTipService.ToolTip="Notes"/>
                <NavigationViewItem Content="Mail" Icon="Mail"
ToolTipService.ToolTip="Mail"/>
            </NavigationViewItem.MenuItems>
        </NavigationViewItem>
    </NavigationView.MenuItems>
</NavigationView>
```

Adding a hierarchy of items using data binding

Add a hierarchy of menu items to the NavigationView by

- binding the MenuItemsSource property to the hierarchical data
- defining the item template to be a NavigationViewMenuItem, with its Content set to be the label of the menu item, and its MenuItemsSource property bound to the next level of the hierarchy

This example also demonstrates the Expanding and Collapsed events. These events are raised for a menu item with children.

XAML

```
<Page ... >
    <Page.Resources>
        <DataTemplate x:Key="NavigationViewMenuItem"
x:DataType="local:Category">
            <NavigationViewItem Content="{x:Bind Name}" MenuItemsSource="
{x:Bind Children}"/>
        </DataTemplate>
    </Page.Resources>

    <Grid>
        <NavigationView x:Name="navview"
    MenuItemsSource="{x:Bind Categories, Mode=OneWay}"
    MenuItemTemplate="{StaticResource NavigationViewMenuItem}"
    ItemInvoked="{x:Bind OnItemInvoked}"
    Expanding="OnItemExpanding"
    Collapsed="OnItemCollapsed"
    PaneDisplayMode="Left">
            <StackPanel Margin="10,10,0,0">
                <TextBlock Margin="0,10,0,0" x:Name="ExpandingItemLabel"
Text="Last Expanding: N/A"/>
                <TextBlock x:Name="CollapsedItemLabel" Text="Last Collapsed:
N/A"/>
            </StackPanel>
        </NavigationView>
    </Grid>
</Page>
```

C#

```
public class Category
{
    public String Name { get; set; }
    public String CategoryIcon { get; set; }
    public ObservableCollection<Category> Children { get; set; }
}

public sealed partial class HierarchicalNavigationViewDataBinding : Page
{
    public HierarchicalNavigationViewDataBinding()
```

```
    {
        this.InitializeComponent();
    }

    public ObservableCollection<Category> Categories = new
ObservableCollection<Category>()
    {
        new Category(){
            Name = "Menu item 1",
            CategoryIcon = "Icon",
            Children = new ObservableCollection<Category>() {
                new Category(){
                    Name = "Menu item 2",
                    CategoryIcon = "Icon",
                    Children = new ObservableCollection<Category>() {
                        new Category() {
                            Name  = "Menu item 3",
                            CategoryIcon = "Icon",
                            Children = new ObservableCollection<Category>()
{
                                new Category() { Name  = "Menu item 4",
CategoryIcon = "Icon" },
                                new Category() { Name  = "Menu item 5",
CategoryIcon = "Icon" }
                            }
                        }
                    }
                }
            }
        },
        new Category(){
            Name = "Menu item 6",
            CategoryIcon = "Icon",
            Children = new ObservableCollection<Category>() {
                new Category(){
                    Name = "Menu item 7",
                    CategoryIcon = "Icon",
                    Children = new ObservableCollection<Category>() {
                        new Category() { Name  = "Menu item 8", CategoryIcon
= "Icon" },
                        new Category() { Name  = "Menu item 9", CategoryIcon
= "Icon" }
                    }
                }
            }
        },
        new Category(){ Name = "Menu item 10", CategoryIcon = "Icon" }
    };

    private void OnItemInvoked(object sender,
NavigationViewItemInvokedEventArgs e)
    {
        var clickedItem = e.InvokedItem;
        var clickedItemContainer = e.InvokedItemContainer;
    }
```

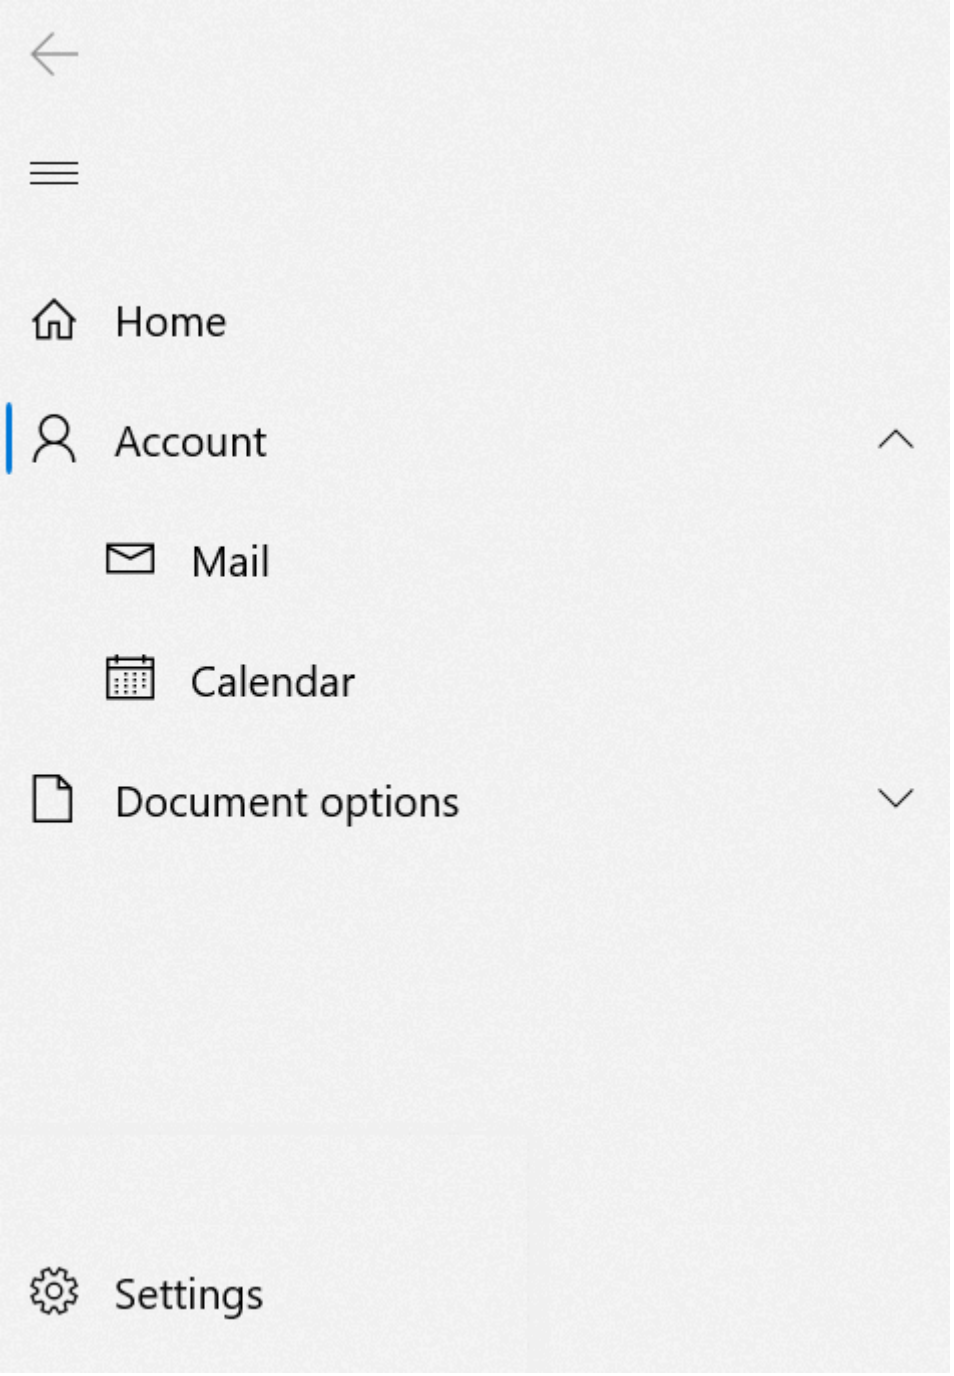
```
    private void OnItemExpanding(object sender,
NavigationViewItemExpandingEventArgs e)
    {
        var nvib = e.ExpandingItemContainer;
        var name = "Last expanding: " + nvib.Content.ToString();
        ExpandingItemLabel.Text = name;
    }
    private void OnItemCollapsed(object sender,
NavigationViewItemCollapsedEventArgs e)
    {
        var nvib = e.CollapsedItemContainer;
        var name = "Last collapsed: " + nvib.Content;
        CollapsedItemLabel.Text = name;
    }
}
```

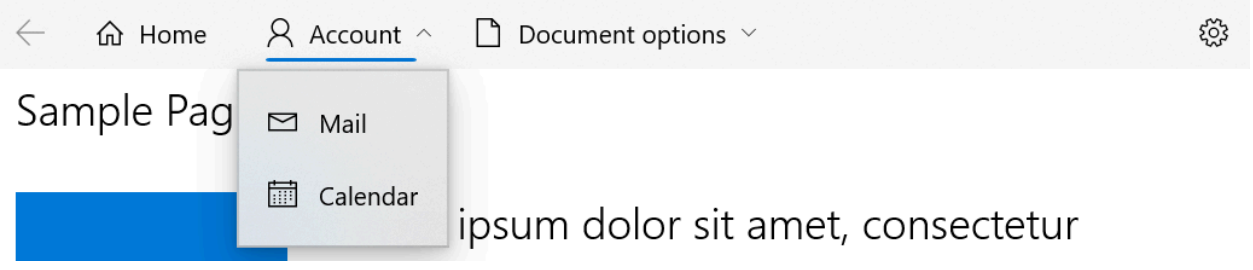
Selection

By default, any item can contain children, be invoked, or be selected.

When providing users with a hierarchical tree of navigation options, you may choose to make parent items non-selectable, for example when your app doesn't have a destination page associated with that parent item. If your parent items *are* selectable, it's recommend you use the Left-Expanded or Top pane display modes. LeftCompact mode will cause the user to navigate to the parent item in order to open the child subtree every time it's invoked.

Selected items will draw their selection indicators along their left edge when in left mode or their bottom edge when in top mode. Shown below are NavigationViews in left and top mode where a parent item is selected.





The selected item may not always remain visible. If a child in a collapsed/non-expanded subtree is selected, their first visible ancestor will show as selected. The selection indicator will move back to the selected item if/when the sub-tree is expanded.

For example - in the above image, the Calendar item may be selected by the user, and then the user may collapse its subtree. In this case, the selection indicator would show up underneath the Account item as Account is Calendar's first visible ancestor. The

selection indicator will move back to the Calendar item as the user expands the subtree again.

The entire NavigationView will show no more than one selection indicator.

In both Top and Left modes, clicking the arrows on NavigationViewItems will expand or collapse the subtree. Clicking or tapping *elsewhere* on the NavigationViewItem will trigger the `ItemInvoked` event, and it will also collapse or expand the subtree.

To prevent an item from showing the selection indicator when invoked, set its SelectsOnInvoked property to False, as shown below:

XAML

```
<Page ...>
    <Page.Resources>
        <DataTemplate x:Key="NavigationViewMenuItem"
x:DataType="local:Category">
            <NavigationViewItem Content="{x:Bind Name}"
            MenuItemsSource="{x:Bind Children}"
            SelectsOnInvoked="{x:Bind IsLeaf}"/>
        </DataTemplate>
    </Page.Resources>

    <Grid>
        <NavigationView x:Name="navview"
    MenuItemsSource="{x:Bind Categories, Mode=OneWay}"
    MenuItemTemplate="{StaticResource NavigationViewMenuItem}">
        </NavigationView>
    </Grid>
</Page>
```

C#

```
public class Category
{
    public String Name { get; set; }
    public String CategoryIcon { get; set; }
    public ObservableCollection<Category> Children { get; set; }
    public bool IsLeaf { get; set; }
}

public sealed partial class HierarchicalNavigationViewDataBinding : Page
{
    public HierarchicalNavigationViewDataBinding()
    {
        this.InitializeComponent();
    }

    public ObservableCollection<Category> Categories = new
ObservableCollection<Category>()
```

```
    {
        new Category(){
            Name = "Menu item 1",
            CategoryIcon = "Icon",
            Children = new ObservableCollection<Category>() {
                new Category(){
                    Name = "Menu item 2",
                    CategoryIcon = "Icon",
                    Children = new ObservableCollection<Category>() {
                        new Category() {
                            Name  = "Menu item 3",
                            CategoryIcon = "Icon",
                            Children = new ObservableCollection<Category>()
{
                                new Category() { Name  = "Menu item 4",
CategoryIcon = "Icon", IsLeaf = true },
                                new Category() { Name  = "Menu item 5",
CategoryIcon = "Icon", IsLeaf = true }
                            }
                        }
                    }
                }
            }
        },
        new Category(){
            Name = "Menu item 6",
            CategoryIcon = "Icon",
            Children = new ObservableCollection<Category>() {
                new Category(){
                    Name = "Menu item 7",
                    CategoryIcon = "Icon",
                    Children = new ObservableCollection<Category>() {
                        new Category() { Name  = "Menu item 8", CategoryIcon
= "Icon", IsLeaf = true },
                        new Category() { Name  = "Menu item 9", CategoryIcon
= "Icon", IsLeaf = true }
                    }
                }
            }
        },
        new Category(){ Name = "Menu item 10", CategoryIcon = "Icon", IsLeaf
= true }
    };
}
```

Keyboarding within hierarchical NavigationView

Users can move focus around the NavigationView using their keyboard. The arrow keys expose "inner navigation" within the pane and follow the interactions provided in tree view. The key actions change when navigating through the NavigationView or its flyout

menu, which is displayed in Top and Left-compact modes of HierarchicalNavigationView. Below are the specific actions that each key can take in a hierarchical NavigationView:

Expand table

Key	In Left Mode	In Top Mode	In Flyout
Up	Moves focus to the item directly above the item currently in focus.	Does nothing.	Moves focus to the item directly above the item currently in focus.
Down	Moves focus directly below the item currently in focus.*	Does nothing.	Moves focus directly below the item currently in focus.*
Right	Does nothing.	Moves focus to the item directly to the right of the item currently in focus.	Does nothing.
Left	Does nothing.	Moves focus to the item directly to the left the item currently in focus.	Does nothing.
Space/Enter	If item has children, expands/collapses item and does not change focus.	If item has children, expands children into a flyout and places focus on first item in flyout.	Invokes/selects item and closes flyout.
Esc	Does nothing.	Does nothing.	Closes flyout.

The space or enter key always invokes/selects an item.

*Note that the items do not need to be visually adjacent, focus will move from the last item in the pane's list to the settings item.

NavigationView customization

Pane Backgrounds

By default, the NavigationView pane uses a different background depending on the display mode:

- the pane is a solid grey color when expanded on the left, side-by-side with the content (in Left mode).

- the pane uses in-app acrylic when open as an overlay on top of content (in Top, Minimal, or Compact mode).

To modify the pane background, you can override the XAML theme resources used to render the background in each mode. (This technique is used rather than a single PaneBackground property in order to support different backgrounds for different display modes.)

This table shows which theme resource is used in each display mode.

Expand table

Display mode	Theme resource
Left	NavigationViewExpandedPaneBackground
LeftCompact LeftMinimal	NavigationViewDefaultPaneBackground
Top	NavigationViewTopPaneBackground

This example shows how to override the theme resources in App.xaml. When you override theme resources, you should always provide "Default" and "HighContrast" resource dictionaries at a minimum, and dictionaries for "Light" or "Dark" resources as needed. For more info, see ResourceDictionary.ThemeDictionaries.

> **Important**
>
> This code shows how to use the WinUI 2 version of AcrylicBrush. If you use the platform version of AcrylicBrush instead, the minimum version for your app project must be SDK 16299 or greater. To use the platform version, remove all references to `muxm:`.

XAML

```
<Application ... xmlns:muxm="using:Microsoft.UI.Xaml.Media" ...>
    <Application.Resources>
        <ResourceDictionary>
            <ResourceDictionary.MergedDictionaries>
                <XamlControlsResources
xmlns="using:Microsoft.UI.Xaml.Controls"/>
                <ResourceDictionary>
                    <ResourceDictionary.ThemeDictionaries>
                        <ResourceDictionary x:Key="Default">
                            <!-- The "Default" theme dictionary is used
unless a specific
```

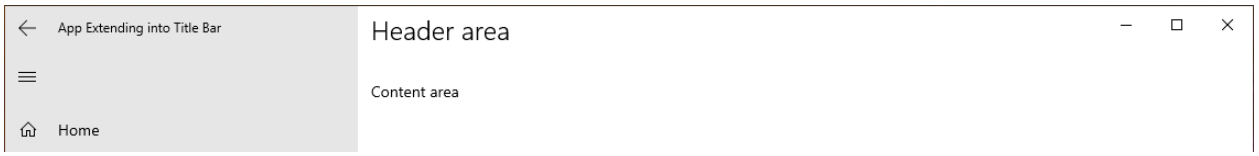
```
                                light, dark, or high contrast dictionary is
provided. These
                                resources should be tested with both the
light and dark themes,
                                and specific light or dark resources
provided as needed. -->
                            <muxm:AcrylicBrush
x:Key="NavigationViewDefaultPaneBackground"
                                BackgroundSource="Backdrop"
                                TintColor="LightSlateGray"
                                TintOpacity=".6"/>
                            <muxm:AcrylicBrush
x:Key="NavigationViewTopPaneBackground"
                                BackgroundSource="Backdrop"
                                TintColor="{ThemeResource
SystemAccentColor}"
                                TintOpacity=".6"/>
                            <LinearGradientBrush
x:Key="NavigationViewExpandedPaneBackground"
                                  StartPoint="0.5,0" EndPoint="0.5,1">
                                <GradientStop Color="LightSlateGray"
Offset="0.0" />
                                <GradientStop Color="White" Offset="1.0" />
                            </LinearGradientBrush>
                        </ResourceDictionary>
                        <ResourceDictionary x:Key="HighContrast">
                            <!-- Always include a "HighContrast" dictionary
when you override
                                theme resources. This empty dictionary
ensures that the
                                default high contrast resources are used
when the user
                                turns on high contrast mode. -->
                        </ResourceDictionary>
                    </ResourceDictionary.ThemeDictionaries>
                </ResourceDictionary>
            </ResourceDictionary.MergedDictionaries>
        </ResourceDictionary>
    </Application.Resources>
</Application>
```

Top whitespace

> The `IsTitleBarAutoPaddingEnabled` property requires WinUI 2.2 or later.

Some apps choose to customize their window's title bar, potentially extending their app content into the title bar area. When NavigationView is the root element in apps that extend into the title bar **using the ExtendViewIntoTitleBar API**, the control automatically adjusts the position of its interactive elements to prevent overlap with the draggable region.

If your app specifies the draggable region by calling the Window.SetTitleBar method and you would prefer to have the back and menu buttons draw closer to the top of your app window, set IsTitleBarAutoPaddingEnabled to `false`.



XAML

```
<muxc:NavigationView x:Name="NavView" IsTitleBarAutoPaddingEnabled="False">
```

Remarks

To further adjust the position of NavigationView's header area, override the *NavigationViewHeaderMargin* XAML theme resource, for example in your Page resources.

XAML

```
<Page.Resources>
    <Thickness x:Key="NavigationViewHeaderMargin">12,0</Thickness>
</Page.Resources>
```

This theme resource modifies the margin around NavigationView.Header.

UWP and WinUI 2

> **Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.

This section contains information you need to use the control in a UWP or WinUI 2 app.

The NavigationView control for UWP apps is included as part of WinUI 2. For more info, including installation instructions, see WinUI 2. APIs for this control exist in both the Windows.UI.Xaml.Controls and Microsoft.UI.Xaml.Controls namespaces.

- ✓ **UWP APIs:** Windows.UI.Xaml.Controls.NavigationView class
- ✓ **WinUI 2 Apis:** Microsoft.UI.Xaml.Controls.NavigationView class
- ✓ Open the WinUI 2 Gallery app and see the NavigationView in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles, templates, and features for all controls. Some features of NavigationView, such as *top* and *hierarchical* navigation, require Windows 10, version 1809 (SDK 17763) or later, or WinUI 2.

To use the code in this article with WinUI 2, use an alias in XAML (we use `muxc`) to represent the Windows UI Library APIs that are included in your project. See Get Started with WinUI 2 for more info.

XAML

```
xmlns:muxc="using:Microsoft.UI.Xaml.Controls"

<muxc:NavigationView />
```

Pivot

Article • 02/26/2025

The Pivot control enables touch-swiping between a small set of content sections.

Is this the right control?

> ⚠ **Warning**
>
> The Pivot control is not recommended for **Windows 11 design patterns**. We strongly recommend using one of these alternatives instead:
>
> - **WinUI 3** - Use the **SelectorBar** control.
> - **WinUI 2/UWP** - Use a **NavigationView** or **TabView** control instead of a Pivot control. See the **Use NavigationView instead of Pivot** section for an example.

To create a Pivot-like UI when using WinUI 3 and the Windows App SDK, use the SelectorBar control.

To create a tabbed UI, use a TabView control.

To achieve common top navigation patterns, we recommend using NavigationView, which automatically adapts to different screen sizes and allows for greater customization.

Some key differences between the NavigationView and Pivot are listed here:

- Pivot supports touch-swiping to switch between items.

- Overflow items in a Pivot carousel, while NavigationView uses a menu dropdown overflow so that users can see all items.
- Pivot handles navigation between content sections, while NavigationView allows for more control over navigation behavior.

Use NavigationView instead of Pivot

If your app's UI uses the Pivot control, you can convert Pivot to NavigationView following this example.

This XAML creates a NavigationView with 3 sections of content, like the example Pivot in Create a pivot control.

XAML

```
<NavigationView x:Name="rootNavigationView" Header="Category Title"
 ItemInvoked="NavView_ItemInvoked">
    <NavigationView.MenuItems>
        <NavigationViewItem Content="Section 1" x:Name="Section1Content" />
        <NavigationViewItem Content="Section 2" x:Name="Section2Content" />
        <NavigationViewItem Content="Section 3" x:Name="Section3Content" />
    </NavigationView.MenuItems>

    <Frame x:Name="ContentFrame" />
</NavigationView>

<Page x:Class="AppName.Section1Page">
    <TextBlock Text="Content of section 1."/>
</Page>

<Page x:Class="AppName.Section2Page">
    <TextBlock Text="Content of section 2."/>
</Page>

<Page x:Class="AppName.Section3Page">
    <TextBlock Text="Content of section 3."/>
</Page>
```

NavigationView provides more control over navigation customization and requires corresponding code-behind. To accompany the above XAML, use the following code-behind:

C#

```
private void NavView_ItemInvoked(NavigationView sender,
NavigationViewItemInvokedEventArgs args)
{
   var navOptions = new FrameNavigationOptions
```

```
    {
        TransitionInfoOverride = args.RecommendedNavigationTransitionInfo,
        IsNavigationStackEnabled = false,
    };

    switch (args.InvokedItemContainer.Name)
    {
        case nameof(Section1Content):
            ContentFrame.NavigateToType(typeof(Section1Page), null,
navOptions);
            break;

        case nameof(Section2Content):
            ContentFrame.NavigateToType(typeof(Section2Page), null,
navOptions);
            break;

        case nameof(Section3Content):
            ContentFrame.NavigateToType(typeof(Section3Page), null,
navOptions);
            break;
    }
}
```

This code mimics the Pivot control's built-in navigation experience, minus the touch-swiping experience between content sections. However, as you can see, you could also customize several points, including the animated transition, navigation parameters, and stack capabilities.

Create a pivot control

> ⚠ **Warning**
>
> The Pivot control is not recommended for Windows 11 design patterns. We strongly recommend using one of these alternatives instead:
>
> - **WinUI 3** - Use the SelectorBar control.
> - **WinUI 2/UWP** - Use a NavigationView or TabView control instead of a Pivot control. See the Use NavigationView instead of Pivot section for an example.

This XAML creates a basic Pivot control with 3 sections of content.

XAML

```
<Pivot x:Name="rootPivot" Title="Category Title">
    <PivotItem Header="Section 1">
```

```
        <!--Pivot content goes here-->
        <TextBlock Text="Content of section 1."/>
    </PivotItem>
    <PivotItem Header="Section 2">
        <!--Pivot content goes here-->
        <TextBlock Text="Content of section 2."/>
    </PivotItem>
    <PivotItem Header="Section 3">
        <!--Pivot content goes here-->
        <TextBlock Text="Content of section 3."/>
    </PivotItem>
</Pivot>
```

Pivot items

Pivot is an ItemsControl, so it can contain a collection of items of any type. Any item you add to the Pivot that is not explicitly a PivotItem is implicitly wrapped in a PivotItem. Because a Pivot is often used to navigate between pages of content, it's common to populate the Items collection directly with XAML UI elements. Or, you can set the ItemsSource property to a data source. Items bound in the ItemsSource can be of any type, but if they aren't explicitly PivotItems, you must define an ItemTemplate and HeaderTemplate to specify how the items are displayed.

You can use the SelectedItem property to get or set the Pivot's active item. Use the SelectedIndex property to get or set the index of the active item.

Pivot headers

You can use the LeftHeader and RightHeader properties to add other controls to the Pivot header.

For example, you can add a CommandBar in the Pivot's RightHeader.

XAML

```
<Pivot>
    <Pivot.RightHeader>
        <CommandBar>
                <AppBarButton Icon="Add"/>
                <AppBarSeparator/>
                <AppBarButton Icon="Edit"/>
                <AppBarButton Icon="Delete"/>
                <AppBarSeparator/>
                <AppBarButton Icon="Save"/>
        </CommandBar>
```

```
    </Pivot.RightHeader>
</Pivot>
```

Pivot interaction

The control features these touch gesture interactions:

- Tapping on a pivot item header navigates to that header's section content.
- Swiping left or right on a pivot item header navigates to the adjacent section.
- Swiping left or right on section content navigates to the adjacent section.

The control comes in two modes:

Stationary

- Pivots are stationary when all pivot headers fit within the allowed space.
- Tapping on a pivot label navigates to the corresponding page, though the pivot itself will not move. The active pivot is highlighted.

Carousel

- Pivots carousel when all pivot headers don't fit within the allowed space.
- Tapping a pivot label navigates to the corresponding page, and the active pivot label will carousel into the first position.
- Pivot items in a carousel loop from last to first pivot section.

> **Tip**
>
> - Avoid using more than 5 headers when using carousel mode, as looping more than 5 can become confusing.
> - Pivot headers should not carousel in a 10ft environment. Set the IsHeaderItemsCarouselEnabled property to `false` if your app will run on Xbox.

UWP and WinUI 2

> **Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that

use **WinUI 2**. See the UWP API reference for platform specific information and examples.

This section contains information you need to use the control in a UWP or WinUI 2 app.

APIs for this control exist in the Windows.UI.Xaml.Controls namespace.

- ✓ **UWP APIs:** Pivot class
- ✓ Open the WinUI 2 Gallery app and see the Pivot in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles and templates for all controls.

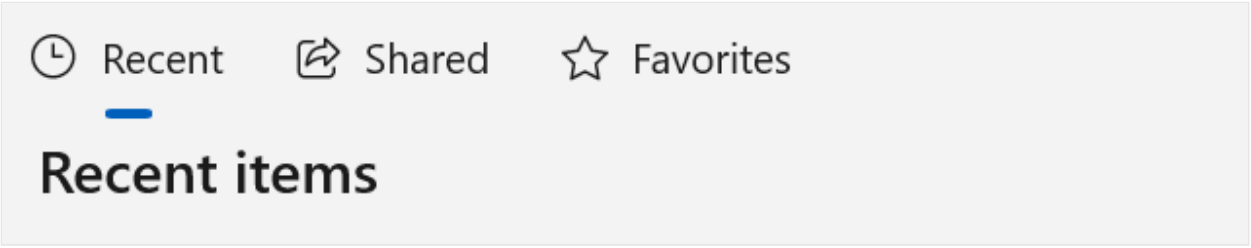
Selector bar

Article • 02/26/2025

A selector bar lets a user switch between a small number of different sets or views of data. One item at a time can be selected.



When a user selects an item in the selector bar, you typically change the view by either:

- navigating between different pages in your app.
- changing the data shown in a collection control.

The selector bar is a light-weight control that supports an icon and text. It's intended to present a limited number of options so it does not rearrange items to adapt to different window sizes.

Is this the right control?

Use a SelectorBar when you want to let a user navigate between a limited number of views or pages and only one option can be selected at once.

Some examples include:

- Switching between "Recent," "Shared," and "Favorites" pages, where each page displays a unique list of content.
- Switching between "All," "Unread," "Flagged," and "Urgent" views, where each view displays a uniquely filtered list of email items.

When should a different control be used?

There are some scenarios where another control may be more appropriate to use.

- Use NavigationView when you require consistent, top-level app navigation that adapts to different window sizes.
- Use TabView when the user should be able to open, close, rearrange, or tear off new views of the content.
- Use PipsPager when you need regular pagination of a single data view.

- Use RadioButtons when an option is not selected by default, and context is unrelated to page navigation.

Create a SelectorBar control

✔ **Important APIs**: SelectorBar class, Items property, SelectionChanged event, SelectorBarItem class

Open the WinUI 3 Gallery app and see the SelectorBar in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

This XAML creates a basic SelectorBar control with 3 sections of content.

XAML

```
<SelectorBar x:Name="SelectorBar">
    <SelectorBarItem x:Name="SelectorBarItemRecent"
                     Text="Recent" Icon="Clock"/>
    <SelectorBarItem x:Name="SelectorBarItemShared"
                     Text="Shared" Icon="Share"/>
    <SelectorBarItem x:Name="SelectorBarItemFavorites"
                     Text="Favorites" Icon="Favorite"/>
</SelectorBar>
```

This shows how to add a SelectorBarItem in code.

C#

```
SelectorBarItem newItem = new SelectorBarItem()
{
    Text = "New Item",
    Icon = new SymbolIcon(Symbol.Add)
};
selectorBar.Items.Add(newItem);
```

SelectorBar items

You populate the SelectorBar Items collection with SelectorBarItem objects. You can do this directly in XAML or in code. Because it's intended to display a limited number of

options, SelectorBar does not have an `ItemsSource` property for binding to an external collection of items.

Item content

The SelectorBarItem class provides Text and Icon properties that you use to set the content of your selector bar. You can set one or both properties; however, we recommend that you set the `Text` property to make the item more meaningful.

The `Icon` property takes an IconElement, so you can use any of these derived icon types:

- AnimatedIcon
- BitmapIcon
- FontIcon
- IconSourceElement
- ImageIcon
- PathIcon
- SymbolIcon

> **Note**
>
> SelectorBarItem inherits the **Child** property from ItemContainer. You can use this property to set the content, but we don't recommend this. Content set this way will not get the styling and visual states provided by the SelectorBarItem control template.

Item selection

You can use the SelectedItem property to get or set the SelectorBar's active item. This is synchronized with the SelectorBarItem's IsSelected property. If you set either property, the other is updated automatically.

Whenever the SelectorBar gets focus and `SelectedItem` is `null`, `SelectedItem` is automatically set to the first focusable instance in the Items collection, if any exists.

Whenever the selected item is removed from the `Items` collection, the `SelectedItem` property is set to `null`. If `SelectedItem` is set to `null` while the SelectorBar has focus, SelectorBar will have no item selected but keeps focus.

Setting `SelectedItem` to an element that is not currently in the `Items` collection throws an exception.

There is no `SelectedIndex` property, but you can get the index of the `SelectedItem` like this:

C#

```
int currentSelectedIndex =
    selectorBar.Items.IndexOf(selectorBar.SelectedItem);
```

Selection changed

Handle the SelectionChanged event to respond to the users selection and change what is shown to the user. The `SelectionChanged` event is raised when an item is selected in any of these ways:

- UI Automation
- Tab focus (and a new item is selected)
- Left and right navigation within the SelectorBar
- Tapped event through mouse or touch
- Programmatic selection (through either the SelectorBar.SelectedItem property or SelectorBarItem's IsSelected property).

When a user selects an item, you typically change the view by either navigating between different pages in your app or changing the data shown in a collection control. Examples of both are shown here.

Navigate with transition animations

> **Tip**
>
> You can find these examples in the **SelectorBar page of the WinUI Gallery app**. Use the WinUI Gallery app to run and view the full code.

This example demonstrates handling the SelectionChanged event to navigate between different pages. The navigation uses the SlideNavigationTransitionEffect to slide the pages in from the left or right, as appropriate.

XAML

```
<SelectorBar x:Name="SelectorBar2"
             SelectionChanged="SelectorBar2_SelectionChanged">
    <SelectorBarItem x:Name="SelectorBarItemPage1" Text="Page1"
                     IsSelected="True" />
    <SelectorBarItem x:Name="SelectorBarItemPage2" Text="Page2" />
    <SelectorBarItem x:Name="SelectorBarItemPage3" Text="Page3" />
    <SelectorBarItem x:Name="SelectorBarItemPage4" Text="Page4" />
    <SelectorBarItem x:Name="SelectorBarItemPage5" Text="Page5" />
</SelectorBar>

<Frame x:Name="ContentFrame" IsNavigationStackEnabled="False" />
```

C#

```
int previousSelectedIndex = 0;

private void SelectorBar2_SelectionChanged
             (SelectorBar sender, SelectorBarSelectionChangedEventArgs args)
{
    SelectorBarItem selectedItem = sender.SelectedItem;
    int currentSelectedIndex = sender.Items.IndexOf(selectedItem);
    System.Type pageType;

    switch (currentSelectedIndex)
    {
        case 0:
            pageType = typeof(SamplePage1);
            break;
        case 1:
            pageType = typeof(SamplePage2);
            break;
        case 2:
            pageType = typeof(SamplePage3);
            break;
        case 3:
            pageType = typeof(SamplePage4);
            break;
        default:
            pageType = typeof(SamplePage5);
            break;
    }

    var slideNavigationTransitionEffect =
            currentSelectedIndex - previousSelectedIndex > 0 ?
                SlideNavigationTransitionEffect.FromRight :
                SlideNavigationTransitionEffect.FromLeft;

    ContentFrame.Navigate(pageType, null, new
SlideNavigationTransitionInfo()
                            { Effect = slideNavigationTransitionEffect });
```

```
    previousSelectedIndex = currentSelectedIndex;
}
```

Display different collections in an ItemsView

This example shows how to change the data source of an ItemsView when the user selects an option in the SelectorBar.

XAML

```
<SelectorBar x:Name="SelectorBar3"
             SelectionChanged="SelectorBar3_SelectionChanged">
    <SelectorBarItem x:Name="SelectorBarItemPink" Text="Pink"
                     IsSelected="True"/>
    <SelectorBarItem x:Name="SelectorBarItemPlum" Text="Plum"/>
    <SelectorBarItem x:Name="SelectorBarItemPowderBlue" Text="PowderBlue"/>
</SelectorBar>

<ItemsView x:Name="ItemsView3"
           ItemTemplate="{StaticResource ColorsTemplate}"/>
    <ItemsView.Layout>
        <UniformGridLayout/>
    </ItemsView.Layout>
</ItemsView/>
```

C#

```
private void SelectorBar3_SelectionChanged
             (SelectorBar sender, SelectorBarSelectionChangedEventArgs args)
{
    if (sender.SelectedItem == SelectorBarItemPink)
    {
        ItemsView3.ItemsSource = PinkColorCollection;
    }
    else if (sender.SelectedItem == SelectorBarItemPlum)
    {
        ItemsView3.ItemsSource = PlumColorCollection;
    }
    else
    {
        ItemsView3.ItemsSource = PowderBlueColorCollection;
    }
}
```

UWP and WinUI 2

ⓘ Important

The SelectorBar control is not available for UWP and WinUI 2. For alternatives, see NavigationView or TabView.

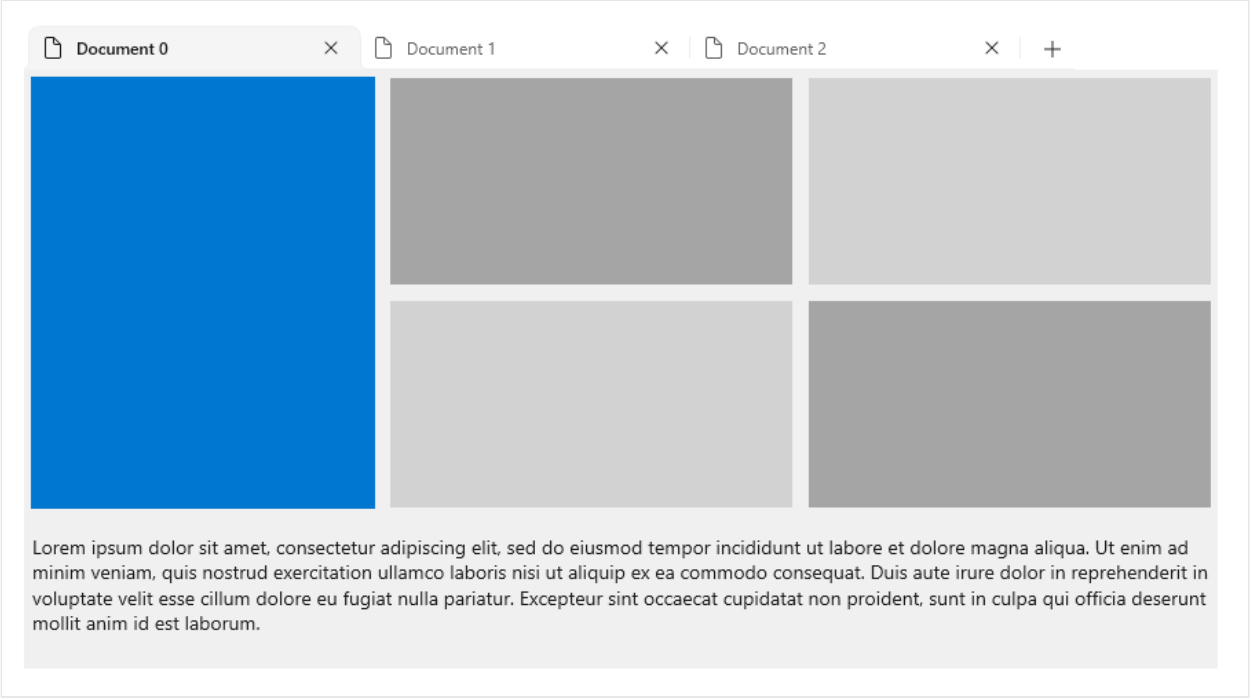
Tab view

Article • 01/16/2025

The TabView control is a way to display a set of tabs and their respective content. TabView controls are useful for displaying several pages (or documents) of content while letting a user rearrange, close, or open new tabs.



Is this the right control?

In general, tabbed UIs come in one of two distinct styles that differ in function and appearance:

- **Static tabs** are the sort of tabs often found in settings windows. They contain a set number of pages in a fixed order that usually contain predefined content.
- **Document tabs** are the sort of tabs found in a browser, such as Microsoft Edge. Users can create, remove, and rearrange tabs; move tabs between windows; and change the content of tabs.

By default, TabView is configured to provide document tabs. We recommend TabView when users will be able to:

- Dynamically open, close, or rearrange tabs.
- Open documents or web pages directly into tabs.
- Drag and drop tabs between windows.

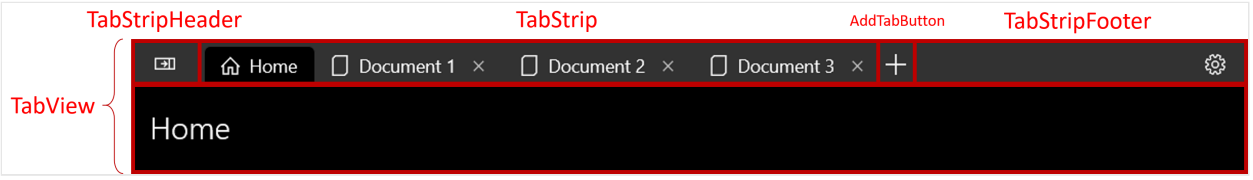
The TabView API does allow configuring the control for static tabs. However, to follow Windows design guidance, and if there are more than a few static navigation items, consider using a NavigationView control.

Anatomy

Tabbed UI is created with a TabView control and one or more TabViewItem controls. The TabView hosts instances of TabViewItem, which represents a single tab and it's content.

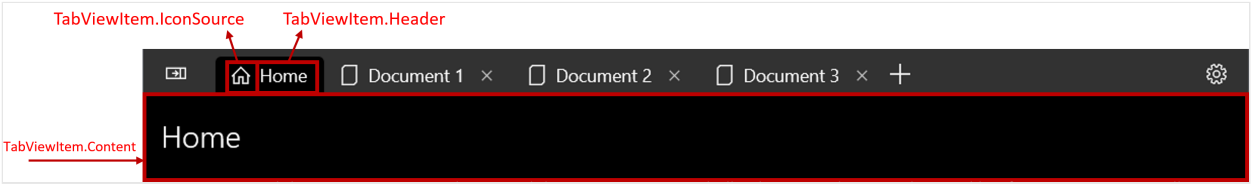
TabView parts

This image shows the parts of the TabView control. The *tab strip* has a header and footer, but unlike a document, the tab strip's header and footer are on the far left and far right of the strip, respectively.



TabViewItem parts

This image shows the parts of the TabViewItem control. Although the content is displayed inside of the TabView control, the content is actually a part of the TabViewItem.



Recommendations

Tab selection

Most users have experience using document tabs simply by using a web browser. When they use document tabs in your app, their experience informs their expectations for how your tabs should behave.

No matter how the user interacts with a set of document tabs, there should always be an active tab. If the user closes the selected tab or breaks the selected tab out into

another window, another tab should become the active tab. TabView attempts to do this automatically selecting the next tab. If you have a good reason that your app should allow a TabView with an unselected tab, the TabView's content area will simply be blank.

Keyboard navigation

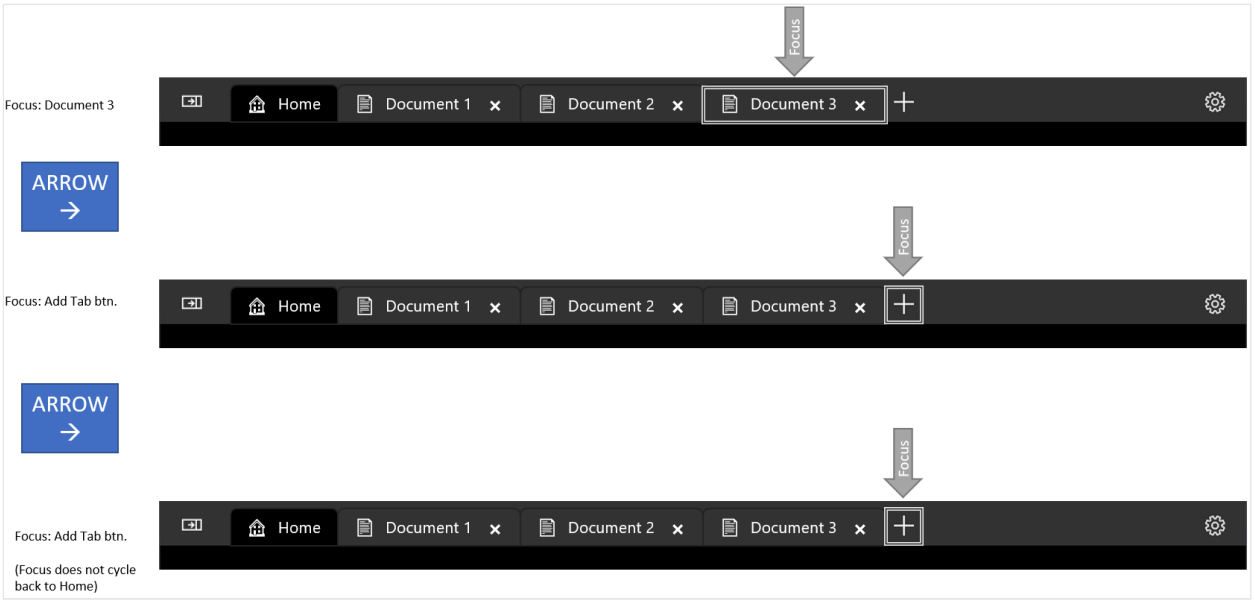
TabView supports many common keyboard navigation scenarios by default. This section explains the built-in functionality, and provides recommendations on additional functionality that might be helpful for some apps.

Tab and cursor key behavior

When focus moves into the *TabStrip* area, the selected TabViewItem gains focus. The user can then use the Left and Right arrow keys to move focus (not selection) to other tabs in the tab strip. Arrow focus is trapped inside the tab strip and the add tab (+) button, if one is present. To move focus out of the tab strip area, the user can press the `Tab` key, which will move focus to the next focusable element.

Move focus via Tab

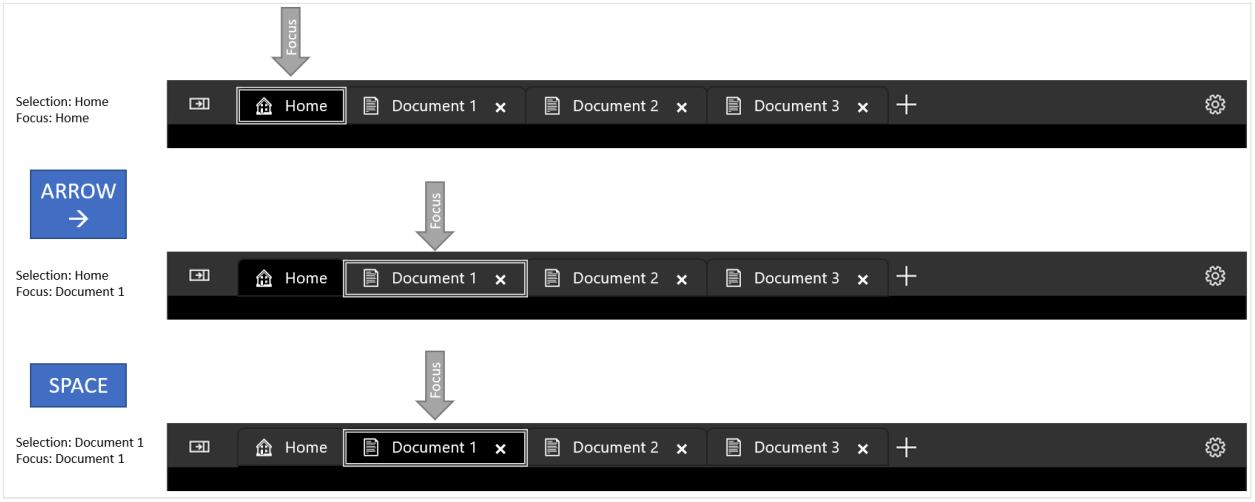
Arrow keys do not cycle focus



Selecting a tab

When a TabViewItem has focus, press `Space` or `Enter` to select that TabViewItem.

Use arrow keys to move focus, then press `Space` to select tab.



Shortcuts for selecting adjacent tabs

Press `Ctrl+Tab` to select the next TabViewItem. Press `Ctrl+Shift+Tab` to select the previous TabViewItem. For these purposes, the tab list is "looped," so selecting the next tab while the last tab is selected will cause the first tab to become selected.

Closing a tab

Press `Ctrl + F4` to raise the TabCloseRequested event. Handle the event and close the tab if appropriate.

> **Tip**
>
> For more information, see Keyboard guidance for developers later in this article.

Create a tab view

✓ **Important APIs**: TabView class, TabViewItem class

Open the WinUI 3 Gallery app and see the TabView in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

The examples in this section show a variety of ways to configure a TabView control.

Tab view items

Each tab in a TabView is represented by a TabViewItem control, which includes both the tab that's shown in the tab strip and the content shown below the tab strip.

Configure a tab

For each TabViewItem, you can set a header and an icon, and specify whether the user can close the tab.

- The Header property is typically set to a string value that provides a descriptive label for the tab. However, the `Header` property can be any object. You can also use the HeaderTemplate property to specify a DataTemplate that defines how bound header data should be displayed.
- Set the IconSource property to specify an icon for the tab.
- By default, the tab shows a *close button* (X). You can set the IsClosable property to `false` to hide the close button and ensure that a user can't close the tab. (If you close tabs in your app code outside of a *close requested* event, you should first check that `IsClosable` is `true`.)

For the TabView, you can configure several options that apply to all tabs.

- By default, the close button is always shown for closable tabs. You can set the CloseButtonOverlayMode property to `OnPointerOver` to change this behavior. In

this case, the selected tab always shows the close button if it is closable, but unselected tabs show the close button only when the tab is closable and the user has their pointer over it.

- You can set the TabWidthMode property to change how tabs are sized. (The `Width` property is ignored on `TabViewItem`.) These are the options in the TabViewWidthMode enumeration:
  - `Equal` - Each tab has the same width. This is the default.
  - `SizeToContent` - Each tab adjusts its width to the content within the tab.
  - `Compact` - Unselected tabs collapse to show only their icon. The selected tab adjusts to display the content within the tab.

Content

The elements displayed in the selected tab are added to the Content property of the TabViewItem. TabViewItem is a ContentControl, so you can add any type of object as content. You can also apply a DataTemplate to the ContentTemplate property. See the ContentControl class for more information.

The examples in this article show a simple case of adding text directly to the `Content` element in XAML. However, real UI is typically more complex. A common way to add complex UI as the content of a tab is to encapsulate it in a UserControl or a Page, and add that as the content of the TabViewItem. This example assumes your app has a XAML UserControl called `PictureSettingsControl`.

XAML

```
<TabViewItem>
    <TabViewItem.Content>
        <local:PictureSettingsControl/>
    </TabViewItem.Content>
</TabViewItem>
```

Static tabs

This example shows a simple TabView with two *static tabs*. Both tab items are added in XAML as content of the TabView.

To make a TabView static, use these settings:

- Set the IsAddTabButtonVisible property to `false` to hide the *add tab* button and prevent the AddTabButtonClick event from being raised.

- Set the CanReorderTabs property to `false` to prevent the user from dragging tabs into a different order.
- On each TabViewItem, set the IsClosable property to false to hide the *tab close* button prevent the user from raising the TabCloseRequested event.

XAML

```
<TabView VerticalAlignment="Stretch"
         IsAddTabButtonVisible="False"
         CanReorderTabs="False">
    <TabViewItem Header="Picture" IsClosable="False">
        <TabViewItem.IconSource>
            <SymbolIconSource Symbol="Pictures"/>
        </TabViewItem.IconSource>
        <TabViewItem.Content>
            <StackPanel Padding="12">
                <TextBlock Text="Picture settings"
                    Style="{ThemeResource TitleTextBlockStyle}"/>
            </StackPanel>
        </TabViewItem.Content>
    </TabViewItem>
    <TabViewItem Header="Sound" IsClosable="False">
        <TabViewItem.IconSource>
            <SymbolIconSource Symbol="Audio"/>
        </TabViewItem.IconSource>
        <TabViewItem.Content>
            <StackPanel Padding="12">
                <TextBlock Text="Sound settings"
                    Style="{ThemeResource TitleTextBlockStyle}"/>
            </StackPanel>
        </TabViewItem.Content>
    </TabViewItem>
</TabView>
```

Document tabs

By default, the TabView is configured for *document tabs*. The user can add new tabs, rearrange tabs, and close tabs. In this configuration, you need to handle the AddTabButtonClick and TabCloseRequested events to enable the functionality.

When tabs are added to a TabView, there might eventually be too many tabs to display in your tab strip. In this case, scroll bumpers will appear that let the user scroll the tab strip left and right to access hidden tabs.

This example creates a simple TabView along with event handlers to support opening and closing tabs. The `TabView_AddTabButtonClick` event handler shows how to add a TabViewItem in code.

XAML

```
<TabView VerticalAlignment="Stretch"
         AddTabButtonClick="TabView_AddTabButtonClick"
         TabCloseRequested="TabView_TabCloseRequested">
    <TabViewItem Header="Home" IsClosable="False">
        <TabViewItem.IconSource>
            <SymbolIconSource Symbol="Home" />
        </TabViewItem.IconSource>
        <TabViewItem.Content>
            <StackPanel Padding="12">
                <TextBlock Text="TabView content"
                           Style="{ThemeResource TitleTextBlockStyle}"/>
            </StackPanel>
        </TabViewItem.Content>
    </TabViewItem>
</TabView>
```

C#

```
// Add a new tab to the TabView.
private void TabView_AddTabButtonClick(TabView sender, object args)
{
    var newTab = new TabViewItem();
    newTab.Header = $"New Document {sender.TabItems.Count}";
    newTab.IconSource = new SymbolIconSource() { Symbol = Symbol.Document };
    newTab.Content = new TextBlock() { Text = $"Content for new tab
{sender.TabItems.Count}.",
                                       Padding = new Thickness(12) };
    sender.TabItems.Add(newTab);
    sender.SelectedItem = newTab;
}

// Remove the requested tab from the TabView.
private void TabView_TabCloseRequested(TabView sender,
                                       TabViewTabCloseRequestedEventArgs
args)
{
    sender.TabItems.Remove(args.Tab);
}
```

Close the window when the last tab is closed

If all tabs in your app are closeable and your app window should close when the last tab is closed, you should also close the window in the TabCloseRequested event handler.

First, in the `App.xaml.cs` file, add a `public static` property that will let you access the `Window` instance from the `Page` that hosts the TabView. (See User interface migration.)

C#

```
public partial class App : Application
{
    // ... code removed.

    // Add this.
    public static Window Window { get { return m_window; } }
    // Update this to make it static.
    private static Window m_window;
}
```

Then, modify the TabCloseRequested event handler to call Window.Close if all tabs have been removed from the TabView.

C#

```
// Remove the requested tab from the TabView.
// If all tabs have been removed, close the Window.
private void TabView_TabCloseRequested(TabView sender,
                                       TabViewTabCloseRequestedEventArgs
args)
{
    sender.TabItems.Remove(args.Tab);

    if (sender.TabItems.Count == 0)
    {
        App.Window.Close();
    }
}
```

> **Note**
>
> This example works for an app with a single window (`MainWindow`). If your app has multiple windows, or you have enabled tab tear-out, you need to track the windows and then find the correct one to close. See the next section for an example of this.

Tab tear-out

Tab tear-out describes what happens when a user drags a tab out of the TabView's tab strip and moves it to another TabView control, typically in a new window.

Starting in Windows App SDK 1.6, TabView has a CanTearOutTabs property that you can set to provide an enhanced experience for dragging tabs out to a new window. When a

user drags a tab out of the tab strip with this option is enabled, a new window is immediately created during the drag, allowing the user to drag it to the edge of the screen to maximize or snap the window in one smooth motion. This implementation also doesn't use drag-and-drop APIs, so it isn't impacted by any limitations in those APIs.

When you set the CanTearOutTabs property to `true`, it causes the *tab tear-out* events to be raised instead of *drag-and-drop* events. To implement tab tear-out, you must handle these events:

- TabTearOutWindowRequested

  This event occurs when a tab is first dragged out of the tab strip. Handle it to create a new Window and TabView that the tab will be moved to.

- TabTearOutRequested

  This event occurs after a new Window has been provided. Handle it to move the torn-out tab from the originating TabView to a TabView in the new window.

- ExternalTornOutTabsDropping

  This event occurs when a torn-out tab is dragged over an existing TabView. Handle it in the TabView that is receiving the torn-out tab to indicate whether or not the tab should be accepted.

- ExternalTornOutTabsDropped

  This event occurs when a torn-out tab is dragged over an existing TabView and the `ExternalTornOutTabsDropping` event has indicated that the drop is allowed. Handle it in the TabView that is receiving the torn-out tab to remove the tab from the originating TabView and insert it into the receiving TabView at the specified index.

These events are not raised when tab tear-out is enabled: TabDragStarting, TabStripDragOver, TabStripDrop, TabDragCompleted, TabDroppedOutside.

> **⊗ Caution**
>
> Tab tear-out is supported in processes running elevated as Administrator.

The following examples show how to implement the event handlers to support tab tear-out.

Set up the TabView

This XAML sets the CanTearOutTabs property to `true` and sets up the tab tear-out event handlers.

XAML

```
<TabView x:Name="tabView"
     CanTearOutTabs="True"
     TabTearOutWindowRequested="TabView_TabTearOutWindowRequested"
     TabTearOutRequested="TabView_TabTearOutRequested"
     ExternalTornOutTabsDropping="TabView_ExternalTornOutTabsDropping"
     ExternalTornOutTabsDropped="TabView_ExternalTornOutTabsDropped">
    <!-- TabView content -->
</TabView>
```

Create and track a new window

Tab tear-out requires that you create and manage new windows in your app.

> **Tip**
>
> The WinUI Gallery app includes a `WindowHelper` class that makes it easier to manage windows in your app. You can copy it from GitHub in the WinUI Gallery repo: WindowHelper.cs. We recommend this helper class to implement tab tear-out. See the TabViewWindowingSamplePage on GitHub to see how it's used.
>
> In this article, helper methods are copied from `WindowHelper.cs`, but are modified and shown inline for readability.

Here, a list for tracking all active windows is created in `App.xaml.cs`. The `OnLaunched` method is updated to track the window after it's created. (This is not needed if you use the `WindowHelper` class.)

C#

```
static public List<Window> ActiveWindows = new List<Window>();

protected override void
OnLaunched(Microsoft.UI.Xaml.LaunchActivatedEventArgs args)
{
    m_window = new MainWindow();
    // Track this window.
    ActiveWindows.Add(m_window);
    m_window.Activate();
}
```

When tab tear-out begins, a new window is requested. Here, the variable `tabTearOutWindow` provides access to the new window after it's created. The `CreateWindow` and `TrackWindow` helper methods create a new window and add it to the active window tracking list.

After you create the new window, you need to create a new Page and set it as the content of the window. The new Page must contain a TabView control that you will move the torn-out tab into in the `TabTearOutRequested` event handler.

> **Tip**
>
> In this example, we create a new `MainPage` class, since it contains only an empty TabView (no tabs are added directly in XAML). If `MainPage` includes other UI elements that should not appear in the torn-out window, you can create a separate page that includes only elements you require (including at least a TabView), and create an instance of that page.

Finally, assign the AppWindow.Id of the new window to the `args.`NewWindowId property. This will be used in the TabViewTabTearOutRequestedEventArgs.NewWindowId property so you can access the window from that event handler.

C#

```
private Window? tabTearOutWindow = null;

private void TabView_TabTearOutWindowRequested(TabView sender,
TabViewTabTearOutWindowRequestedEventArgs args)
{
    tabTearOutWindow = CreateWindow();
    tabTearOutWindow.Content = new MainPage();
    // Optional window setup, such as setting the icon or
    // extending content into the title bar happens here.
    args.NewWindowId = tabTearOutWindow.AppWindow.Id;
}

private Window CreateWindow()
{
    Window newWindow = new Window
    {
        SystemBackdrop = new MicaBackdrop()
    };
    newWindow.Title = "Torn Out Window";
    TrackWindow(newWindow);
    return newWindow;
}

private void TrackWindow(Window window)
```

```
{
    window.Closed += (sender, args) => {
        App.ActiveWindows.Remove(window);
    };
    App.ActiveWindows.Add(window);
}
```

Close a window when the last tab is closed

As mentioned earlier, you, might want to close the window when the last tab in a TabView is closed. If your app has multiple windows, you need to find the correct window to close in your list of tracked windows. This example shows how to do that.

C#

```
// Remove the requested tab from the TabView.
// If all tabs have been removed, close the Window.
private void TabView_TabCloseRequested(TabView sender,
TabViewTabCloseRequestedEventArgs args)
{
    sender.TabItems.Remove(args.Tab);

    if (sender.TabItems.Count == 0)
    {
        GetWindowForElement(this)?.Close();
    }
}

public Window? GetWindowForElement(UIElement element)
{
    if (element.XamlRoot != null)
    {
        foreach (Window window in App.ActiveWindows)
        {
            if (element.XamlRoot == window.Content.XamlRoot)
            {
                return window;
            }
        }
    }
    return null;
}
```

Move the tab to the new window

After the new window has been provided, you need to remove the torn-out tab from the `sender` TabView and add it to the TabView in the new window. In this example, the

`public AddTabToTabs` helper method let's you access the TabView in the new `MainPage` instance from the original page instance in order to add the torn-out tab to it.

```
C#

private void TabView_TabTearOutRequested(TabView sender,
TabViewTabTearOutRequestedEventArgs args)
{
    if (tabTearOutWindow?.Content is MainPage newPage
        && args.Tabs.FirstOrDefault() is TabViewItem tab)
    {
        sender.TabItems.Remove(tab);
        newPage.AddTabToTabs(tab);
    }
}

// This method provides access to the TabView from
// another page instance so you can add the torn-out tab.
public void AddTabToTabs(TabViewItem tab)
{
    tabView.TabItems.Add(tab);
}
```

Drag a torn-out tab onto another TabView

When a tab has been torn-out and placed into a new window, as shown in the previous steps, one of two things can happen:

- The user can drop the tab and it remains in the new window. The tear-out process ends here and no more events are raised.
- The user can continue to drag the torn-out tab back onto an existing TabView control. In this case, the process continues and several more events are raised to let you remove the tab from the original TabView and insert the external tab into an existing TabView.

When the tab is dragged over the existing TabView, the ExternalTornOutTabsDropping event it raised. In the event handler, you can determine whether inserting the tab into this TabView is allowed. In most cases, you only need to set the `args.`AllowDrop property to `true`. However, if you need to perform any checks before setting that property, you can do that here. If `AllowDrop` is set to `false`, the tab drag action continues and the ExternalTornOutTabsDropped event is not raised.

```
C#

private void TabView_ExternalTornOutTabsDropping(TabView sender,
                        TabViewExternalTornOutTabsDroppingEventArgs args)
```

```
{
    args.AllowDrop = true;
}
```

If `AllowDrop` is set to `true` in the `ExternalTornOutTabsDropping` event handler, the `ExternalTornOutTabsDropped` event is immediately raised.

> **Note**
>
> The *`Dropped`* in the event name does not directly correspond to the idea of a *drop* action in the drag-and-drop APIs. Here, the user does not need to release the tab to perform a *drop* action. The event is raised while the tab is held over the tab strip, and the code is executed to *drop* the tab into the TabView.

The ExternalTornOutTabsDropped event handler follows the same pattern as the TabTearOutRequested event, but inverted; you need to remove the tab from the originating TabView and insert it into the `sender` TabView.

The `sender` TabView is the control that the tab is being inserted into, so we use the `GetParentTabView` helper method to find the originating tab. It starts with the torn-out TabViewItem and uses VisualTreeHelper to walk up the visual tree and find the TabView the item belongs to. After the TabView is found, the TabViewItem is removed from it's TabItems collection and inserted into the `sender` TabView's `TabItems` collection at the index specified by `args.`DropIndex.

C#

```
private void TabView_ExternalTornOutTabsDropped(TabView sender,
                                TabViewExternalTornOutTabsDroppedEventArgs
args)
{
    if (args.Tabs.FirstOrDefault() is TabViewItem tab)
    {
        GetParentTabView(tab)?.TabItems.Remove(tab);
        sender.TabItems.Insert(args.DropIndex, tab);
    }
}

// Starting with the TabViewItem, walk up the
// visual tree until you get to the TabView.
private TabView? GetParentTabView(TabViewItem tab)
{
    DependencyObject current = tab;
    while (current != null)
    {
        if (current is TabView tabView)
```

```
        {
            return tabView;
        }
        current = VisualTreeHelper.GetParent(current);
    }
    return null;
}
```

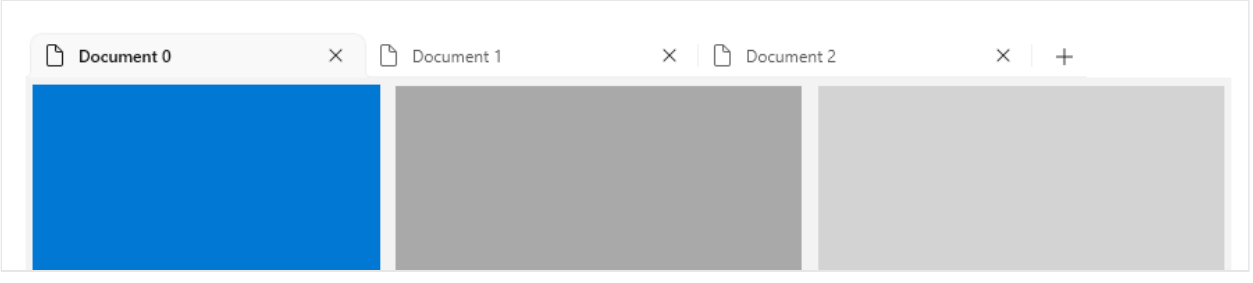
> **Tip**
>
> If you're using the Windows Community Toolkit, you can use the `FindAscendant` helper method in the toolkit's DependencyObjectExtensions instead of `GetParentTabView`.

Display TabView tabs in a window's title bar

Instead of having tabs occupy their own row below a Window's title bar, you can merge the two into the same area. This saves vertical space for your content, and gives your app a modern feel.

Because a user can drag a window by its title bar to reposition the Window, it is important that the title bar is not completely filled with tabs. Therefore, when displaying tabs in a title bar, you must specify a portion of the title bar to be reserved as a draggable area. If you do not specify a draggable region, the entire title bar will be draggable, which prevents your tabs from receiving input events. If your TabView will display in a window's title bar, you should always include a TabStripFooter in your TabView and mark it as a draggable region.

For more information, see Title bar customization



XAML

```
<TabView VerticalAlignment="Stretch">
    <TabViewItem Header="Home" IsClosable="False">
        <TabViewItem.IconSource>
            <SymbolIconSource Symbol="Home" />
        </TabViewItem.IconSource>
```

```
    </TabViewItem>

    <TabView.TabStripFooter>
        <Grid x:Name="CustomDragRegion" Background="Transparent" />
    </TabView.TabStripFooter>
</TabView>
```

C#

```
private void MainPage_Loaded(object sender, RoutedEventArgs e)
{
    App.Window.ExtendsContentIntoTitleBar = true;
    App.Window.SetTitleBar(CustomDragRegion);
    CustomDragRegion.MinWidth = 188;
}
```

> **Note**
>
> How you get a reference to the window may vary depending on how you track windows in your app. For more information, see Close the window when the last tab is closed and Create and track a new window in this article.

Keyboard guidance for developers

> **Tip**
>
> For more information about built-in keyboard support, see Keyboard navigation earlier in this article.

Some applications may require more advanced keyboard control. Consider implementing the following shortcuts if they are appropriate for your app.

> **Warning**
>
> If you are adding a TabView to an existing app, you may have already created keyboard shortcuts that map to the key combinations of the recommended TabView keyboard shortcuts. In this case, you will have to consider whether to keep your existing shortcuts or offer an intuitive tab experience for the user.

- `Ctrl + T` should open a new tab. Generally this tab is populated with a predefined document, or is created empty with a simple way to choose its content. If the user

must choose content for a new tab, consider giving input focus to the content selection control.

- `Ctrl + W` should close the selected tab. Remember, TabView will select the next tab automatically.
- `Ctrl + Shift + T` should open recently closed tabs (or more accurately, open new tabs with the same content as recently closed tabs). Start with the most recently closed tab, and move backwards in time for each subsequent time the shortcut is invoked. Note that this will require maintaining a list of recently closed tabs.
- `Ctrl + 1` should select the first tab in the tab list. Likewise, Ctrl + 2 should select the second tab, Ctrl + 3 should select the third, and so on through Ctrl + 8.
- `Ctrl + 9` should select the last tab in the tab list, regardless of how many tabs are in the list.
- If tabs offer more than just the close command (such as duplicating or pinning a tab), use a context menu to show all available actions that can be performed on a tab.

Implement browser-style keyboarding behavior

This example implements a number of the above recommendations on a TabView. Specifically, This example implements `Ctrl + T`, `Ctrl + W`, `Ctrl + 1-8`, and `Ctrl + 9`.

XAML

```
<TabView>
    <!-- ... some tabs ... -->
    <TabView.KeyboardAccelerators>
        <KeyboardAccelerator Key="T" Modifiers="Control"
                             Invoked="NewTabKeyboardAccelerator_Invoked" />
        <KeyboardAccelerator Key="W" Modifiers="Control"

Invoked="CloseSelectedTabKeyboardAccelerator_Invoked" />
        <KeyboardAccelerator Key="Number1" Modifiers="Control"

Invoked="NavigateToNumberedTabKeyboardAccelerator_Invoked" />
        <KeyboardAccelerator Key="Number2" Modifiers="Control"

Invoked="NavigateToNumberedTabKeyboardAccelerator_Invoked" />
        <KeyboardAccelerator Key="Number3" Modifiers="Control"

Invoked="NavigateToNumberedTabKeyboardAccelerator_Invoked" />
        <KeyboardAccelerator Key="Number4" Modifiers="Control"

Invoked="NavigateToNumberedTabKeyboardAccelerator_Invoked" />
        <KeyboardAccelerator Key="Number5" Modifiers="Control"

Invoked="NavigateToNumberedTabKeyboardAccelerator_Invoked" />
        <KeyboardAccelerator Key="Number6" Modifiers="Control"
```

```
Invoked="NavigateToNumberedTabKeyboardAccelerator_Invoked" />
        <KeyboardAccelerator Key="Number7" Modifiers="Control"

Invoked="NavigateToNumberedTabKeyboardAccelerator_Invoked" />
        <KeyboardAccelerator Key="Number8" Modifiers="Control"

Invoked="NavigateToNumberedTabKeyboardAccelerator_Invoked" />
        <KeyboardAccelerator Key="Number9" Modifiers="Control"

Invoked="NavigateToNumberedTabKeyboardAccelerator_Invoked" />
    </TabView.KeyboardAccelerators>
</TabView>
```

C#

```
private void NewTabKeyboardAccelerator_Invoked(KeyboardAccelerator sender,
                                               KeyboardAcceleratorInvokedEventArgs
args)
{
    // Create new tab.
    TabView senderTabView = (TabView)args.Element;
    if (senderTabView is not null)
    {
        // (Click handler defined in previous example.)
        TabView_AddTabButtonClick(senderTabView, new EventArgs());
    }
    args.Handled = true;
}

private void CloseSelectedTabKeyboardAccelerator_Invoked(KeyboardAccelerator
sender,

KeyboardAcceleratorInvokedEventArgs args)
{
    TabView tabView = (TabView)args.Element;
    TabViewItem tab = (TabViewItem)tabView.SelectedItem;
    if (tab is not null)
    {
        CloseSelectedTab(tabView, tab);
    }
    args.Handled = true;
}

private void TabView_TabCloseRequested(TabView sender,

            tabToSelect = 3;
            break;
        case Windows.System.VirtualKey.Number5:
            tabToSelect = 4;
            break;
        case Windows.System.VirtualKey.Number6:
            tabToSelect = 5;
            break;
        case Windows.System.VirtualKey.Number7:
            tabToSelect = 6;
            break;
        case Windows.System.VirtualKey.Number8:
            tabToSelect = 7;
            break;
        case Windows.System.VirtualKey.Number9:
            // Select the last tab
            tabToSelect = tabView.TabItems.Count - 1;
            break;
    }

    // Only select the tab if it is in the list.
    if (tabToSelect < tabView.TabItems.Count)
    {
        tabView.SelectedIndex = tabToSelect;
    }
}
```

UWP and WinUI 2

> **Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

The TabView control for UWP apps is included as part of WinUI 2. For more info, including installation instructions, see WinUI 2. APIs for this control exist in the Microsoft.UI.Xaml.Controls namespace.

Tab tear-out APIs are not included in the WinUI 2 version of TabView.

- ✓ **WinUI 2 Apis:** TabView class, TabViewItem class
- ✓ Open the WinUI 2 Gallery app and see the TabView in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles, templates, and features for all controls. WinUI 2.2 or later includes a new template for this control that uses rounded corners. For more info, see Corner radius.

To use the code in this article with WinUI 2, use an alias in XAML (we use `muxc`) to represent the Windows UI Library APIs that are included in your project. See Get Started with WinUI 2 for more info.

XAML

```
xmlns:muxc="using:Microsoft.UI.Xaml.Controls"

<muxc:TabView />
```

Contact card

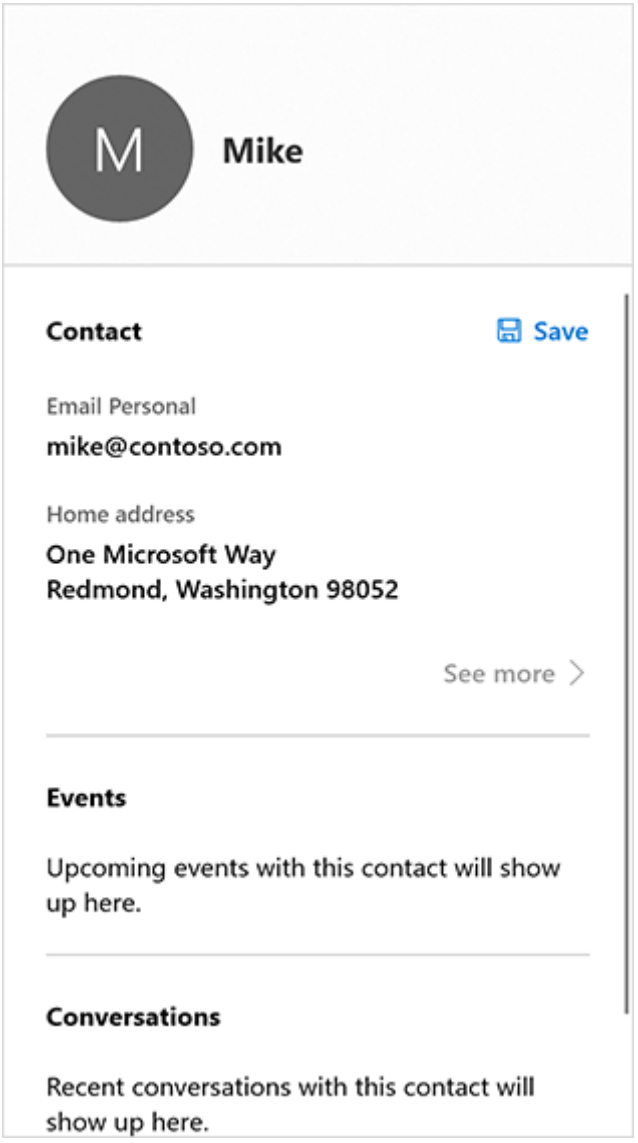
Article • 05/17/2022

The contact card displays contact information, such as the name, phone number, and address, for a Contact (the mechanism Windows uses to represent people and businesses). The contact card also lets the user edit contact info. You can choose to display a compact contact card, or a full contact card that contains additional information.

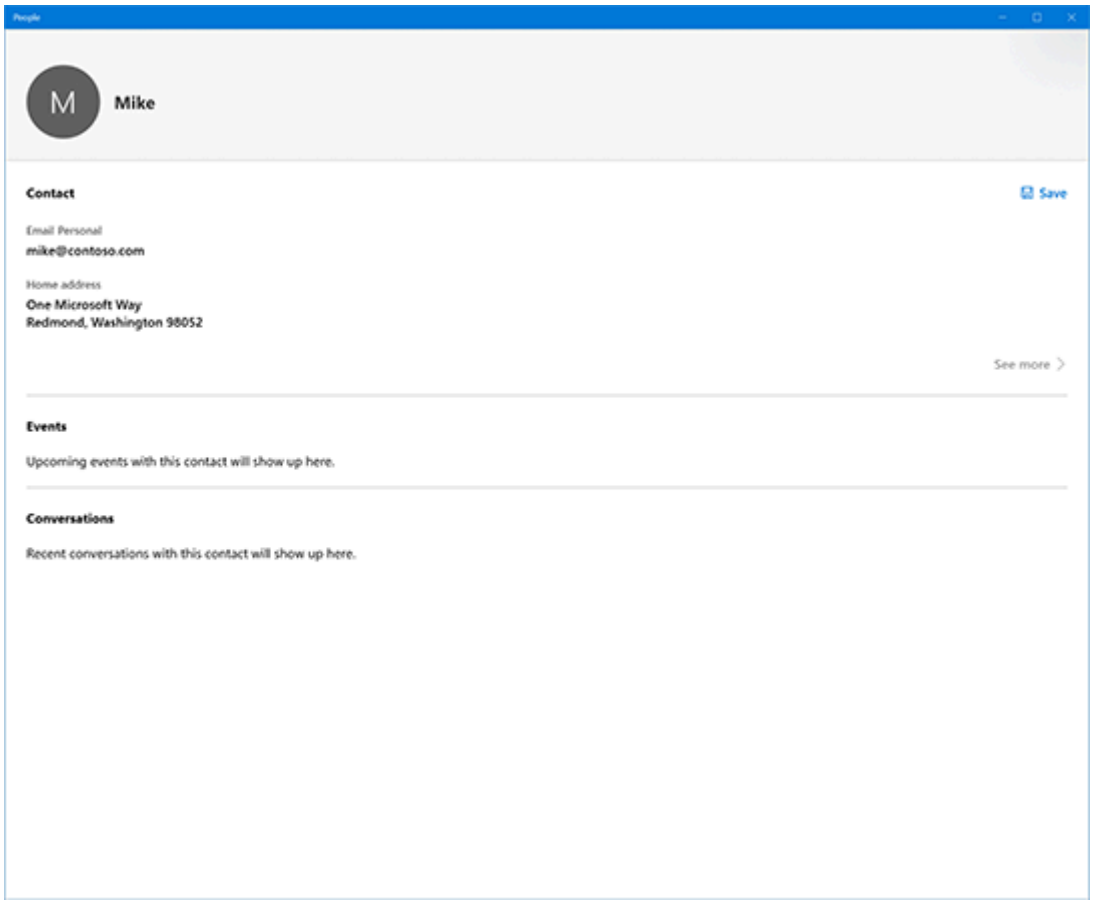
> **Important APIs**: ShowContactCard method, ShowFullContactCard method, IsShowContactCardSupported method, Contact class

There are two ways to display the contact card:

- As a standard contact card that appears in a flyout that is light-dismissable--the contact card disappears when the user clicks outside of it.
- As a full contact card that takes up more space and is not light-dismissable--the user must click **close** to close it.



The standard contact card



The full contact card

Is this the right control?

Use the contact card when you want to display contact info for a contact. If you only want to display the contact's name and picture, use the person picture control.

Show a standard contact card

1. Typically, you show a contact card because the user clicked something: a button or perhaps the person picture control. We don't want to hide the element. To avoid hiding it, we need to create a Rect that describes the location and size of the element.

   Let's create a utility function that does that for us--we'll use it later.

   C#

```
// Gets the rectangle of the element
public static Rect GetElementRectHelper(FrameworkElement element)
{
    // Passing "null" means set to root element.
    GeneralTransform elementTransform =
element.TransformToVisual(null);
    Rect rect = elementTransform.TransformBounds(new Rect(0, 0,
```

```
element.ActualWidth, element.ActualHeight));
    return rect;
}
```

2. Determine whether you can display the contact card by calling the ContactManager.IsShowContactCardSupported method. If it's not supported, display an error message. (This example assumes that you'll be showing the contact card in response to a click event .)

```
C#

// Contact and Contact Managers are existing classes
private void OnUserClickShowContactCard(object sender, RoutedEventArgs
e)
{
    if (ContactManager.IsShowContactCardSupported())
    {
```

3. Use the utility function you created in step 1 to get the bounds of the control that fired the event (so we don't cover it up with the contact card).

```
C#

        Rect selectionRect = GetElementRect((FrameworkElement)sender);
```

4. Get the Contact object you want to display. This example just creates a simple contact, but your code should retrieve an actual contact.

```
C#

            // Retrieve the contact to display
            var contact = new Contact();
            var email = new ContactEmail();
            email.Address = "jsmith@contoso.com";
            contact.Emails.Add(email);
```

5. Show the contact card by calling the ShowContactCard method.

```
C#

        ContactManager.ShowFullContactCard(
            contact, selectionRect, Placement.Default);
    }
}
```

Here's the complete code example:

C#

```
// Gets the rectangle of the element
public static Rect GetElementRect(FrameworkElement element)
{
    // Passing "null" means set to root element.
    GeneralTransform elementTransform = element.TransformToVisual(null);
    Rect rect = elementTransform.TransformBounds(new Rect(0, 0,
element.ActualWidth, element.ActualHeight));
    return rect;
}

// Display a contact in response to an event
private void OnUserClickShowContactCard(object sender, RoutedEventArgs e)
{
    if (ContactManager.IsShowContactCardSupported())
    {
        Rect selectionRect = GetElementRect((FrameworkElement)sender);

        // Retrieve the contact to display
        var contact = new Contact();
        var email = new ContactEmail();
        email.Address = "jsmith@contoso.com";
        contact.Emails.Add(email);

        ContactManager.ShowContactCard(
            contact, selectionRect, Placement.Default);
    }
}
```

Show a full contact card

To show the full contact card, call the ShowFullContactCard method instead of ShowContactCard.

C#

```
private void onUserClickShowContactCard()
{

    Contact contact = new Contact();
    ContactEmail email = new ContactEmail();
    email.Address = "jsmith@hotmail.com";
    contact.Emails.Add(email);

    // Setting up contact options.
```

```
    FullContactCardOptions fullContactCardOptions = new
FullContactCardOptions();

    // Display full contact card on mouse click.
    // Launch the People's App with full contact card
    fullContactCardOptions.DesiredRemainingView =
ViewSizePreference.UseLess;

    // Shows the full contact card by launching the People App.
    ContactManager.ShowFullContactCard(contact, fullContactCardOptions);
}
```

Retrieving "real" contacts

The examples in this article create a simple contact. In a real app, you'd probably want to retrieve an existing contact. For instructions, see the Contacts and calendar article.

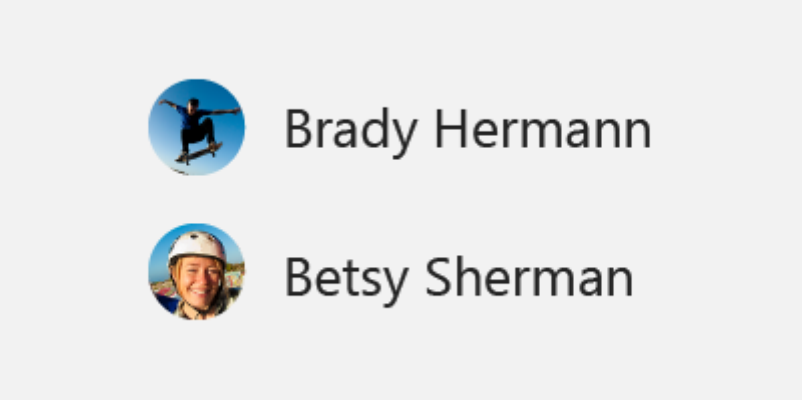
Person picture control

Article • 02/26/2025

The person picture control displays the avatar image for a person, if one is available; if not, it displays the person's initials or a generic glyph. You can use the control to display a Contact object, an object that manages a person's contact info, or you can manually provide contact information, such as a display name and profile picture.

Here are two person picture controls accompanied by two text block elements that display the users' names.

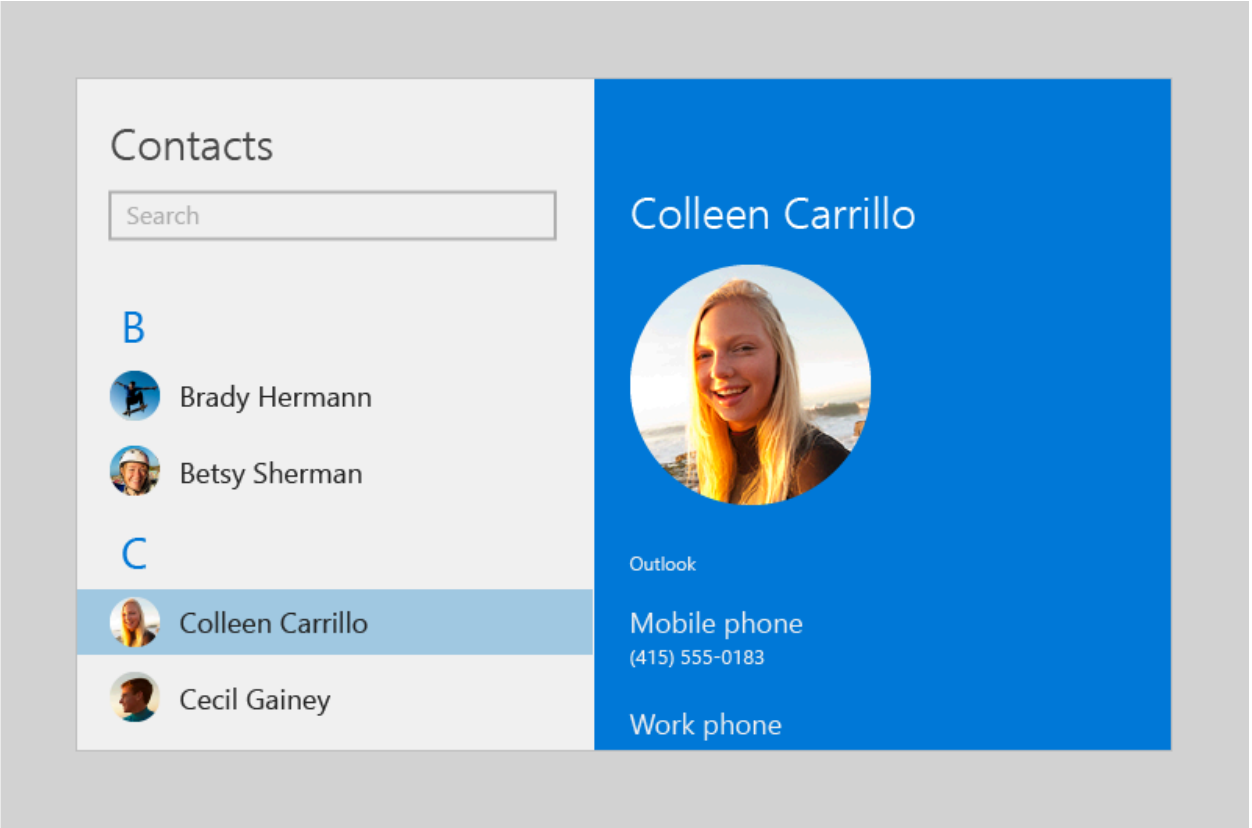


Is this the right control?

Use the person picture when you want to represent a person and their contact information. Here are some examples of when you might use the control:

- To display the current user
- To display contacts in an address book
- To display the sender of a message
- To display a social media contact

The illustration shows the person picture control in a list of contacts:



Create a person picture

✓ **Important APIs:** PersonPicture class

Open the WinUI 3 Gallery app and see PersonPicture in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

To create a person picture, you use the PersonPicture class. This example creates a PersonPicture control and manually provides the person's display name, profile picture, and initials:

XAML

```
<PersonPicture
    DisplayName="Betsy Sherman"
    ProfilePicture="Assets\BetsyShermanProfile.png"
    Initials="BS" />
```

Using the person picture control to display a Contact object

You can use the person picture control to display a Contact object:

XAML

```
<Page
    x:Class="SampleApp.PersonPictureContactExample"
    xmlns="http://schemas.microsoft.com/winfx/2006/xaml/presentation"
    xmlns:x="http://schemas.microsoft.com/winfx/2006/xaml"
    xmlns:local="using:SampleApp"
    xmlns:d="http://schemas.microsoft.com/expression/blend/2008"
    xmlns:mc="http://schemas.openxmlformats.org/markup-compatibility/2006"
    mc:Ignorable="d">

    <StackPanel Background="{ThemeResource
ApplicationPageBackgroundThemeBrush}">

        <PersonPicture
            Contact="{x:Bind CurrentContact, Mode=OneWay}" />

        <Button Click="LoadContactButton_Click">Load contact</Button>
    </StackPanel>
</Page>
```

C#

```
using System;
using System.Collections.Generic;
using System.IO;
using System.Linq;
using System.Runtime.InteropServices.WindowsRuntime;
using Windows.Foundation;
using Windows.Foundation.Collections;
using Windows.UI.Xaml;
using Windows.UI.Xaml.Controls;
using Windows.UI.Xaml.Controls.Primitives;
using Windows.UI.Xaml.Data;
using Windows.UI.Xaml.Input;
using Windows.UI.Xaml.Media;
using Windows.UI.Xaml.Navigation;
using Windows.ApplicationModel.Contacts;

namespace SampleApp
{
    public sealed partial class PersonPictureContactExample : Page,
System.ComponentModel.INotifyPropertyChanged
    {
        public PersonPictureContactExample()
        {
```

```
            this.InitializeComponent();
        }

        private Windows.ApplicationModel.Contacts.Contact _currentContact;
        public Windows.ApplicationModel.Contacts.Contact CurrentContact
        {
            get => _currentContact;
            set
            {
                _currentContact = value;
                PropertyChanged?.Invoke(this,
                    new
System.ComponentModel.PropertyChangedEventArgs(nameof(CurrentContact)));
            }

        }
        public event System.ComponentModel.PropertyChangedEventHandler
PropertyChanged;

        public static async
System.Threading.Tasks.Task<Windows.ApplicationModel.Contacts.Contact>
CreateContact()
        {

            var contact = new Windows.ApplicationModel.Contacts.Contact();
            contact.FirstName = "Betsy";
            contact.LastName = "Sherman";

            // Get the app folder where the images are stored.
            var appInstalledFolder =
                Windows.ApplicationModel.Package.Current.InstalledLocation;
            var assets = await appInstalledFolder.GetFolderAsync("Assets");
            var imageFile = await assets.GetFileAsync("betsy.png");
            contact.SourceDisplayPicture = imageFile;

            return contact;
        }

        private async void LoadContactButton_Click(object sender,
RoutedEventArgs e)
        {
            CurrentContact = await CreateContact();
        }
    }
}
```

> **Note**
>
> To keep the code simple, this example creates a new Contact object. In a real app, you'd let the user select a contact or you'd use a ContactManager to query for a

list of contacts. For info on retrieving and managing contacts, see the Contacts and calendar articles.

Determining which info to display

When you provide a Contact object, the person picture control evaluates it to determine which info it can display.

If an image is available, the control displays the first image it finds, in this order:

1. LargeDisplayPicture
2. SmallDisplayPicture
3. Thumbnail

You can change which image is chosen by setting the PreferSmallImage property to true; this gives the SmallDisplayPicture a higher priority than LargeDisplayPicture.

If there isn't an image, the control displays the contact's name or initials; if there's isn't any name data, the control displays contact data, such as an email address or phone number.

UWP and WinUI 2

> **Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

The PersonPicture control for UWP apps is included as part of WinUI 2. For more info, including installation instructions, see WinUI 2. APIs for this control exist in both the Windows.UI.Xaml.Controls and Microsoft.UI.Xaml.Controls namespaces.

- ✓ **UWP APIs:** PersonPicture class, Contact class, ContactManager class
- ✓ **WinUI 2 Apis:** PersonPicture class
- ✓ Open the WinUI 2 Gallery app and see PersonPicture in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and

functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles, templates, and features for all controls.

To use the code in this article with WinUI 2, use an alias in XAML (we use `muxc`) to represent the Windows UI Library APIs that are included in your project. See Get Started with WinUI 2 for more info.

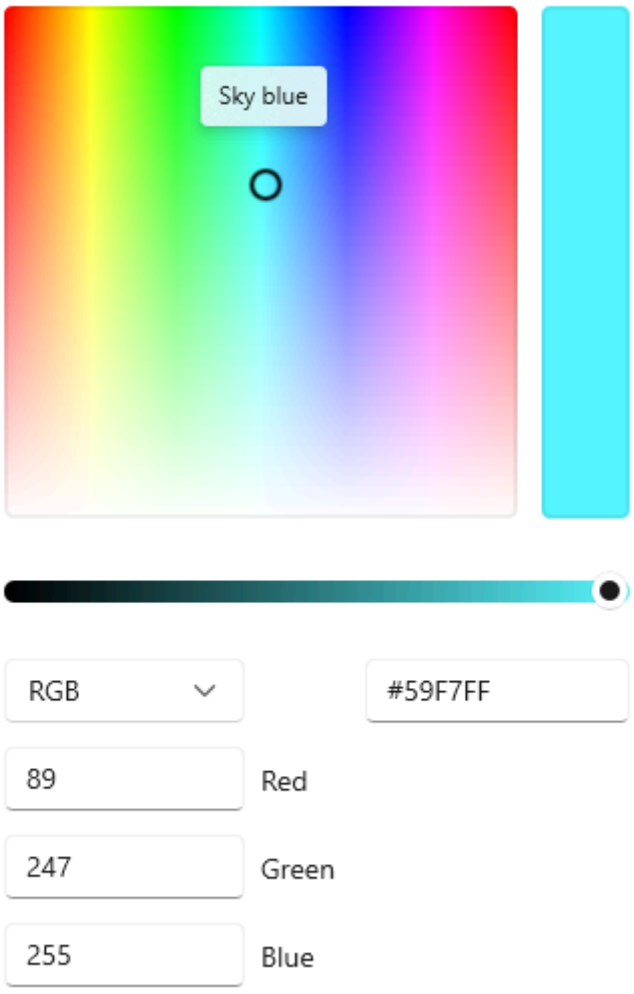
Color picker

Article • 02/26/2025

A color picker is used to browse through and select colors. By default, it lets a user navigate through colors on a color spectrum, or specify a color in either Red-Green-Blue (RGB), Hue-Saturation-Value (HSV), or Hexadecimal text boxes.



Is this the right control?

Use the color picker to let a user select colors in your app. For example, use it to change color settings, such as font colors, background, or app theme colors.

If your app is for drawing or similar tasks using pen, consider using Inking controls along with the color picker.

Recommendations

- Think about what kind of color picking experience is appropriate for your app. Some scenarios may not require granular color picking and would benefit from a simplified picker
- For the most accurate color picking experience, use the square spectrum and ensure it is at least 256x256px, or include the text input fields to let users refine their selected color.
- When used in a flyout, tapping in the spectrum or adjusting the slider alone should not commit the color selection. To commit the selection:
  - Provide commit and cancel buttons to apply or cancel the selection. Hitting the back button or tapping outside of the flyout will dismiss it, and not save the user's selection.
  - Or, commit the selection upon dismissing the flyout, by either tapping outside of the flyout or hitting the back button.

Create a color picker

✔ **Important APIs:** ColorPicker class, Color property, ColorChanged event

Open the WinUI 3 Gallery app and see the ColorPicker in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

This example shows how to create a default color picker in XAML.

XAML

```
<ColorPicker x:Name="myColorPicker"/>
```

By default, the color picker shows a preview of the chosen color on the rectangular bar beside the color spectrum. You can use either the ColorChanged event or the Color property to access the selected color and use it in your app. See the following examples for detailed code.

Bind to the chosen color

When the color selection should take effect immediately, you can either use databinding to bind to the Color property, or handle the ColorChanged event to access the selected color in your code.

In this example, you bind the Color property of a SolidColorBrush that's used as the Fill for a Rectangle directly to the color picker's selected color. Any change to the color picker results in a live change to the bound property.

XAML

```
<ColorPicker x:Name="myColorPicker"
             ColorSpectrumShape="Ring"
             IsColorPreviewVisible="False"
             IsColorChannelTextInputVisible="False"
             IsHexInputVisible="False"/>

<Rectangle Height="50" Width="50">
    <Rectangle.Fill>
        <SolidColorBrush Color="{x:Bind myColorPicker.Color, Mode=OneWay}"/>
    </Rectangle.Fill>
</Rectangle>
```

This example uses a simplified color picker with just the circle and the slider, which is a common "casual" color picking experience. When the color change can be seen and happens in real-time on the affected object, you don't need to show the color preview bar. See the *Customize the color picker* section for more info.

Save the chosen color

In some cases, you don't want to apply the color change immediately. For example, when you host a color picker in a flyout, we recommend that you apply the selected color only after the user confirms the selection or closes the flyout. You can also save the selected color value to use later.

In this example, you host a color picker in a Flyout with Confirm and Cancel buttons. When the user confirms their color choice, you save the selected color to use later in your app.

XAML

```
<Page.Resources>
    <Flyout x:Key="myColorPickerFlyout">
        <RelativePanel>
            <ColorPicker x:Name="myColorPicker"
                         IsColorChannelTextInputVisible="False"
                         IsHexInputVisible="False"/>

            <Grid RelativePanel.Below="myColorPicker"
                  RelativePanel.AlignLeftWithPanel="True"
                  RelativePanel.AlignRightWithPanel="True">
                <Grid.ColumnDefinitions>
```

```
                    <ColumnDefinition/>
                    <ColumnDefinition/>
                </Grid.ColumnDefinitions>
                <Button Content="OK" Click="confirmColor_Click"
                        Margin="0,12,2,0" HorizontalAlignment="Stretch"/>
                <Button Content="Cancel" Click="cancelColor_Click"
                        Margin="2,12,0,0" HorizontalAlignment="Stretch"
                        Grid.Column="1"/>
            </Grid>
        </RelativePanel>
    </Flyout>
</Page.Resources>

<Grid Background="{ThemeResource ApplicationPageBackgroundThemeBrush}">
    <Button x:Name="colorPickerButton"
            Content="Pick a color"
            Flyout="{StaticResource myColorPickerFlyout}"/>
</Grid>
```

C#

```
private Color myColor;

private void confirmColor_Click(object sender, RoutedEventArgs e)
{
    // Assign the selected color to a variable to use outside the popup.
    myColor = myColorPicker.Color;

    // Close the Flyout.
    colorPickerButton.Flyout.Hide();
}

private void cancelColor_Click(object sender, RoutedEventArgs e)
{
    // Close the Flyout.
    colorPickerButton.Flyout.Hide();
}
```

Configure the color picker

Not all fields are necessary to let a user pick a color, so the color picker is flexible. It provides a variety of options that let you configure the control to fit your needs.

For example, when the user doesn't need precise control, like picking a highlighter color in a note taking app, you can use a simplified UI. You can hide the text entry fields and change the color spectrum to a circle.

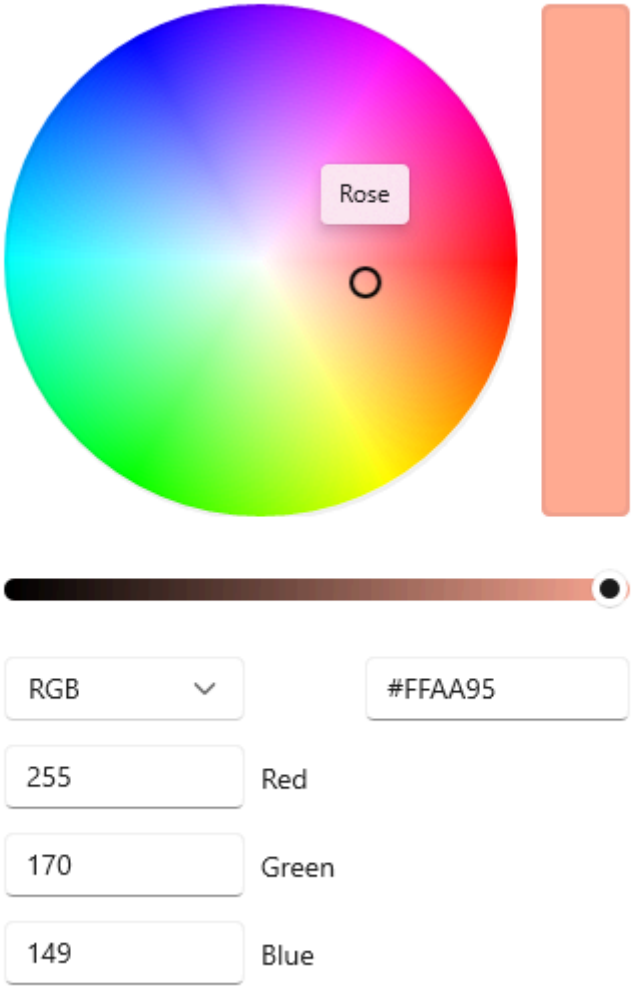
When the user does need precise control, like in a graphic design app, you can show both sliders and text entry fields for each aspect of the color.

Show the circle spectrum

This example shows how to use the ColorSpectrumShape property to configure the color picker to use a circular spectrum instead of the default square.

XAML

```
<ColorPicker x:Name="myColorPicker"
             ColorSpectrumShape="Ring"/>
```



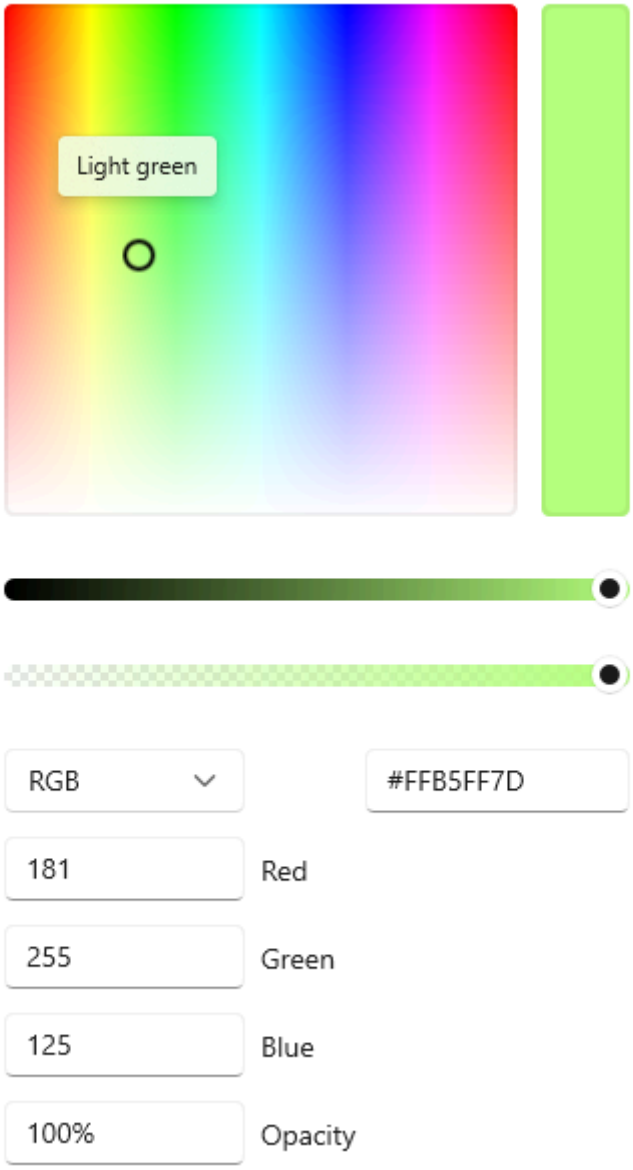
When you must choose between the square and circle color spectrum, a primary consideration is accuracy. A user has more control when they select a specific color using a square because more of the color gamut is shown. You should consider the circle spectrum as more of the "casual" color choosing experience.

Show the alpha channel

In this example, you enable an opacity slider and textbox on the color picker.

XAML

```
<ColorPicker x:Name="myColorPicker"
             IsAlphaEnabled="True"/>
```



Show a simple picker

This example shows how to configure the color picker with a simple UI for "casual" use. You show the circular spectrum and hide the default text input boxes. When the color change can be seen and happens in real-time on the affected object, you don't need to show the color preview bar. Otherwise, you should leave the color preview visible.

XAML

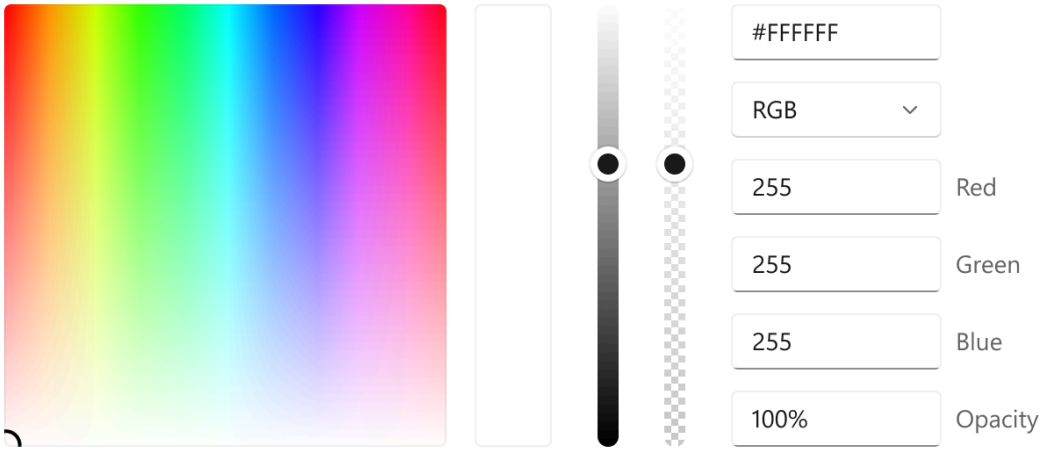
```
<ColorPicker x:Name="myColorPicker"
             ColorSpectrumShape="Ring"
             IsColorPreviewVisible="False"
             IsColorChannelTextInputVisible="False"
             IsHexInputVisible="False"/>
```

Specify the layout direction

Use the Orientation property to specify whether the ColorPicker should align vertically or horizontally. This affects the location of the editing controls relative to the color spectrum. By default, the orientation is Vertical.

XAML

```
<ColorPicker IsAlphaEnabled="True"
             Orientation="Horizontal"/>
```



> **Note**
>
> If the Orientation is set to Horizontal, the ColorPicker does **not** apply the IsMoreButtonVisible property.

Show or hide additional features

This table shows all the options you can use to configure the ColorPicker control.

Expand table

Feature	Properties
Color spectrum	IsColorSpectrumVisible, ColorSpectrumShape, ColorSpectrumComponents
Color preview	IsColorPreviewVisible
Color values	IsColorSliderVisible, IsColorChannelTextInputVisible
Opacity values	IsAlphaEnabled, IsAlphaSliderVisible, IsAlphaTextInputVisible
Hex values	IsHexInputVisible

> **Note**
>
> IsAlphaEnabled must be **true** in order to show the opacity textbox and slider. The visibility of the input controls can then be modified using IsAlphaTextInputVisible and IsAlphaSliderVisible properties. See the API documentation for details.

UWP and WinUI 2

> **Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

The ColorPicker control for UWP apps is included as part of WinUI 2. For more info, including installation instructions, see WinUI 2. APIs for this control exist in both the Windows.UI.Xaml.Controls and Microsoft.UI.Xaml.Controls namespaces.

- ✓ **UWP APIs:** ColorPicker class, Color property, ColorChanged event
- ✓ **WinUI 2 Apis:** ColorPicker class, Color property, ColorChanged event
- ✓ Open the WinUI 2 Gallery app and see the ColorPicker in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles, templates, and features for all controls. WinUI 2.2 or later includes a new template for this control that uses rounded corners. For more info, see Corner radius.

To use the code in this article with WinUI 2, use an alias in XAML (we use `muxc`) to represent the Windows UI Library APIs that are included in your project. See Get Started with WinUI 2 for more info.

XAML

```

Calendar, date, and time controls

Article • 06/09/2022

Date and time controls give you standard, localized ways to let a user view and set date and time values in your app. This article provides design guidelines and helps you pick the right control.

- ✓ Open the WinUI 2 Gallery app and see Date and Time controls in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

Open the WinUI 3 Gallery app and see Date and Time controls in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

Which date or time control should you use?

There are four date and time controls to choose from; the control you use depends on your scenario. Use this info to pick the right control to use in your app.

Expand table

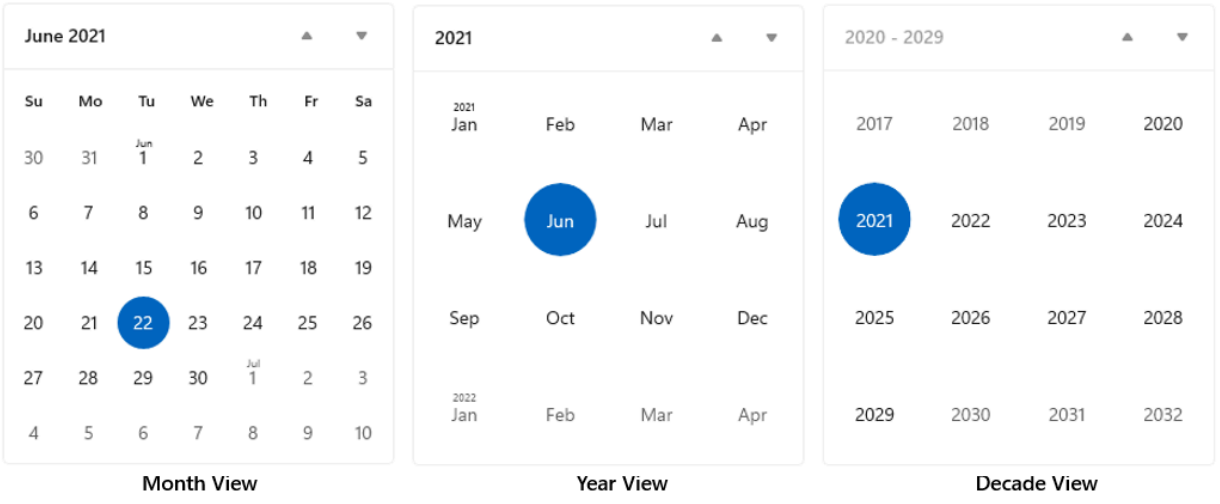
Control	Example	Description
Calendar view		Use to pick a single date or a range of dates from an always visible calendar.

Control	Example	Description
Calendar date picker		Use to pick a single date from a contextual calendar.
Date picker		Use to pick a single known date when contextual info isn't important.
Time picker		Use to pick a single time value.

Calendar view

CalendarView lets a user view and interact with a calendar that they can navigate by month, year, or decade. A user can select a single date or a range of dates. It doesn't have a picker surface and the calendar is always visible.

The calendar view is made up of 3 separate views: the month view, year view, and decade view. By default, it starts with the month view open, but you can specify any view as the startup view.



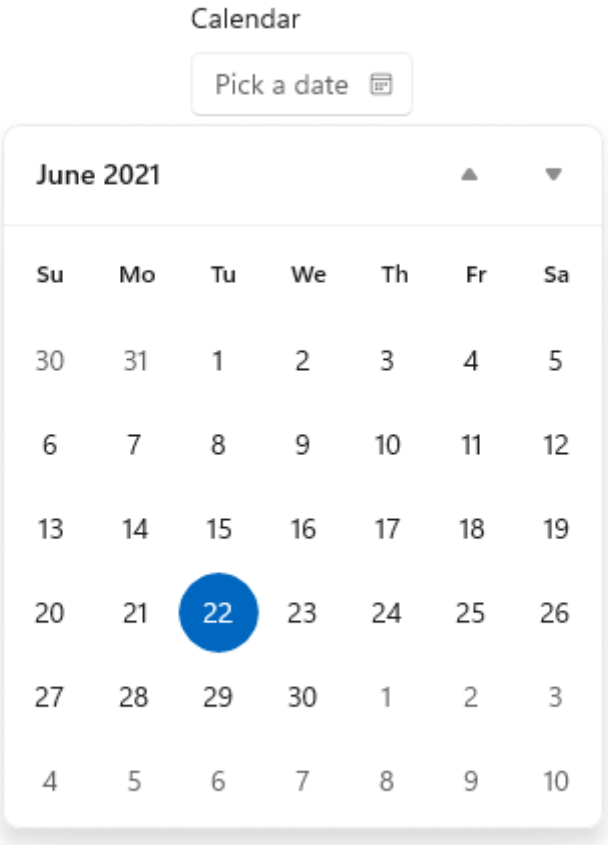
Month View **Year View** **Decade View**

- If you need to let a user select multiple dates, you must use a **CalendarView**.
- If you need to let a user pick only a single date and don't need a calendar to be always visible, consider using a **CalendarDatePicker** or **DatePicker** control.

Calendar date picker

CalendarDatePicker is a drop down control that's optimized for picking a single date from a calendar view where contextual information like the day of the week or fullness of the calendar is important. You can modify the calendar to provide additional context or to limit available dates.

The entry point displays placeholder text if a date has not been set; otherwise, it displays the chosen date. When the user selects the entry point, a calendar view expands for the user to make a date selection. The calendar view overlays other UI; it doesn't push other UI out of the way.



- Use a calendar date picker for things like choosing an appointment or departure date.

Date picker

The **DatePicker** control provides a standardized way to choose a specific date.

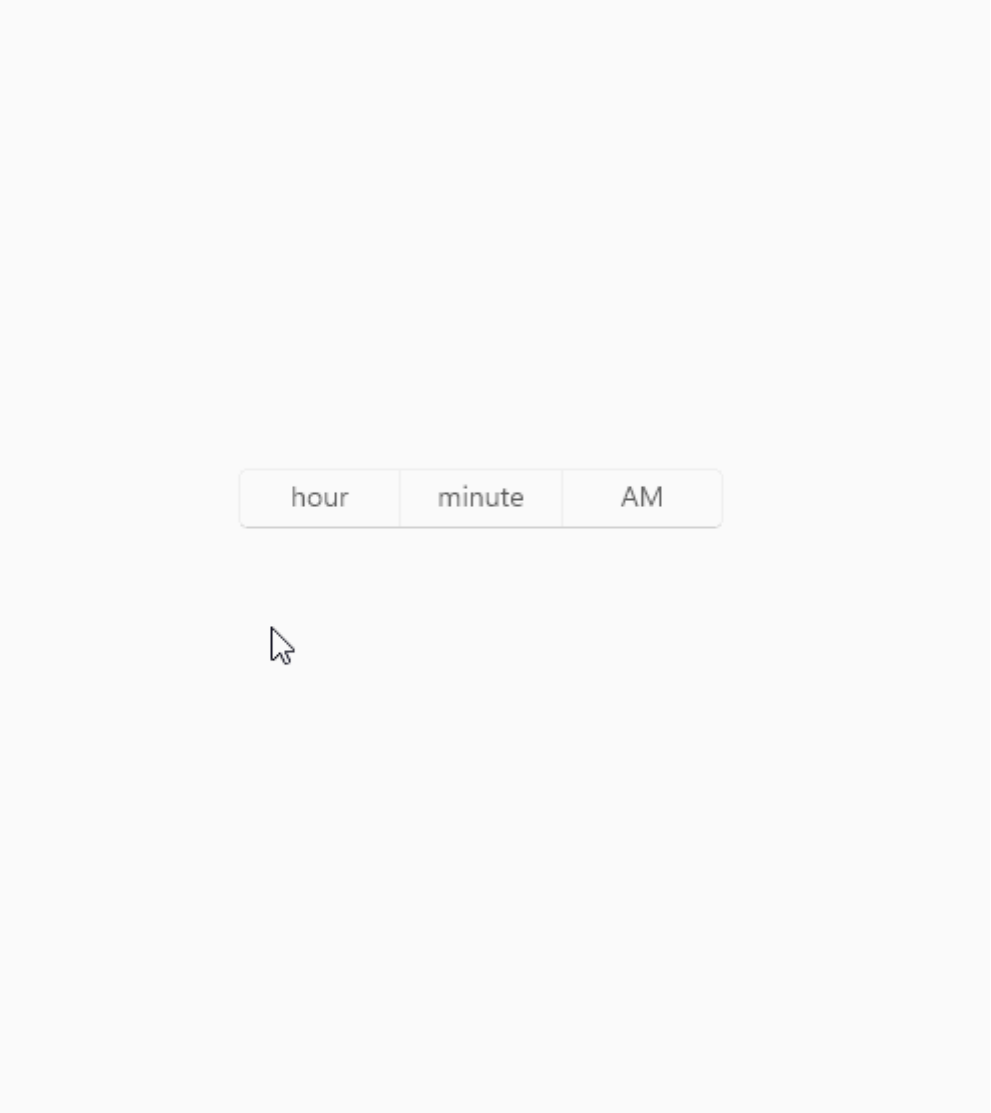
The entry point displays the chosen date, and when the user selects the entry point, a picker surface expands vertically from the middle for the user to make a selection. The date picker overlays other UI; it doesn't push other UI out of the way.

- Use a date picker to let a user pick a known date, such as a date of birth, where the context of the calendar is not important.

Time picker

The **TimePicker** is used to select a single time value for things like appointments or a departure time. It's a static display that is set by the user or in code, but it doesn't update to display the current time.

The entry point displays the chosen time, and when the user selects the entry point, a picker surface expands vertically from the middle for the user to make a selection. The time picker overlays other UI; it doesn't push other UI out of the way.



- Use a time picker to let a user pick a single time value.

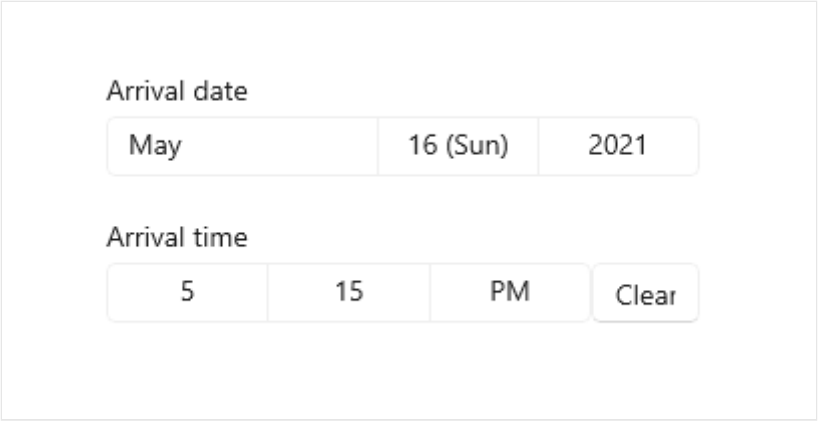
Create a date or time control

See these articles for info and examples specific to each date and time control.

- Calendar view
- Calendar date picker
- Date picker
- Time Picker

Use a date picker and time picker together

This example shows how to use a `DatePicker` and `TimePicker` together to let a user select their arrival date and time. You handle the `SelectedDateChanged` and `SelectedTimeChanged` events to update a single DateTime instance named `arrivalDateTime`. The user can also clear the date and time pickers after they have been set.



XAML

```
<StackPanel>
    <DatePicker x:Name="arrivalDatePicker" Header="Arrival date"
                DayFormat="{}{day.integer} ({dayofweek.abbreviated})"

SelectedDateChanged="ArrivalDatePicker_SelectedDateChanged"/>
    <StackPanel Orientation="Horizontal">
        <TimePicker x:Name="arrivalTimePicker" Header="Arrival time"
                MinuteIncrement="15"

SelectedTimeChanged="ArrivalTimePicker_SelectedTimeChanged"/>
        <Button Content="Clear" Click="ClearDateButton_Click"
                VerticalAlignment="Bottom" Height="30" Width="54"/>
    </StackPanel>
    <TextBlock x:Name="arrivalText" Margin="0,12"/>
</StackPanel>
```

C#

```
public sealed partial class MainPage : Page
{
    DateTime arrivalDateTime;

    public MainPage()
    {
        this.InitializeComponent();

        // Set minimum to the current year and maximum to five years from
now.
        arrivalDatePicker.MinYear = DateTimeOffset.Now;
        arrivalDatePicker.MaxYear = DateTimeOffset.Now.AddYears(5);
    }

    private void ArrivalTimePicker_SelectedTimeChanged(TimePicker sender,
TimePickerSelectedValueChangedEventArgs args)
    {
        if (arrivalTimePicker.SelectedTime != null)
        {
            arrivalDateTime = new DateTime(arrivalDateTime.Year,
arrivalDateTime.Month, arrivalDateTime.Day,
```

```
                                                args.NewTime.Value.Hours,
args.NewTime.Value.Minutes, args.NewTime.Value.Seconds);
            }
            arrivalText.Text = arrivalDateTime.ToString();
        }

        private void ArrivalDatePicker_SelectedDateChanged(DatePicker sender,
DatePickerSelectedValueChangedEventArgs args)
        {
            if (arrivalDatePicker.SelectedDate != null)
            {
                if
(VerifyDateIsFuture((DateTimeOffset)arrivalDatePicker.SelectedDate) == true)
                {
                    arrivalDateTime = new DateTime(args.NewDate.Value.Year,
args.NewDate.Value.Month, args.NewDate.Value.Day,
                                                   arrivalDateTime.Hour,
arrivalDateTime.Minute, arrivalDateTime.Second);
                    arrivalText.Text = arrivalDateTime.ToString();
                }
                else
                {
                    arrivalDatePicker.SelectedDate = null;
                    arrivalText.Text = "Arrival date must be later than today.";
                }
            }
        }

        private bool VerifyDateIsFuture(DateTimeOffset date)
        {
            if (date > DateTimeOffset.Now)
            {
                return true;
            }
            return false;
        }

        private void ClearDateButton_Click(object sender, RoutedEventArgs e)
        {
            arrivalDateTime = new DateTime();
            arrivalDatePicker.SelectedDate = null;
            arrivalTimePicker.SelectedTime = null;
            arrivalText.Text = string.Empty;
        }
    }
```

Globalization

The XAML date controls support each of the calendar systems supported by Windows. These calendars are specified in the Windows.Globalization.CalendarIdentifiers class.

Each control uses the correct calendar for your app's default language, or you can set the **CalendarIdentifier** property to use a specific calendar system.

The time picker control supports each of the clock systems specified in the Windows.Globalization.ClockIdentifiers class. You can set the ClockIdentifier property to use either a 12-hour clock or 24-hour clock. The type of the property is String, but you must use values that correspond to the static string properties of the ClockIdentifiers class. These are: TwelveHour (the string "12HourClock")and TwentyFourHour (the string "24HourClock"). "12HourClock" is the default value.

DateTime and Calendar values

The date objects used in the XAML date and time controls have a different representation depending on your programming language.

- C# and Visual Basic use the System.DateTimeOffset structure that is part of .NET.
- C++/CX uses the Windows::Foundation::DateTime structure.

A related concept is the Calendar class, which influences how dates are interpreted in context. All Windows Runtime apps can use the Windows.Globalization.Calendar class. C# and Visual Basic apps can alternatively use the System.Globalization.Calendar class, which has very similar functionality. (Windows Runtime apps can use the base .NET Calendar class but not the specific implementations; for example, GregorianCalendar.)

.NET also supports a type named DateTime, which is implicitly convertible to a DateTimeOffset. So you might see a "DateTime" type being used in .NET code that's used to set values that are really DateTimeOffset. For more info on the difference between DateTime and DateTimeOffset, see Remarks in the DateTimeOffset class.

> ⓘ **Note**
>
> Properties that take date objects can't be set as a XAML attribute string, because the Windows Runtime XAML parser doesn't have a conversion logic for converting strings to dates as DateTime/DateTimeOffset objects. You typically set these values in code. Another possible technique is to define a date that's available as a data object or in the data context, then set the property as a XAML attribute that references a **{Binding} markup extension** expression that can access the date as data.

Calendar date picker

Article • 02/26/2025

The calendar date picker is a drop down control that's optimized for picking a single date from a calendar view where contextual information like the day of the week or fullness of the calendar is important. You can modify the calendar to provide additional context or to limit available dates.

Is this the right control?

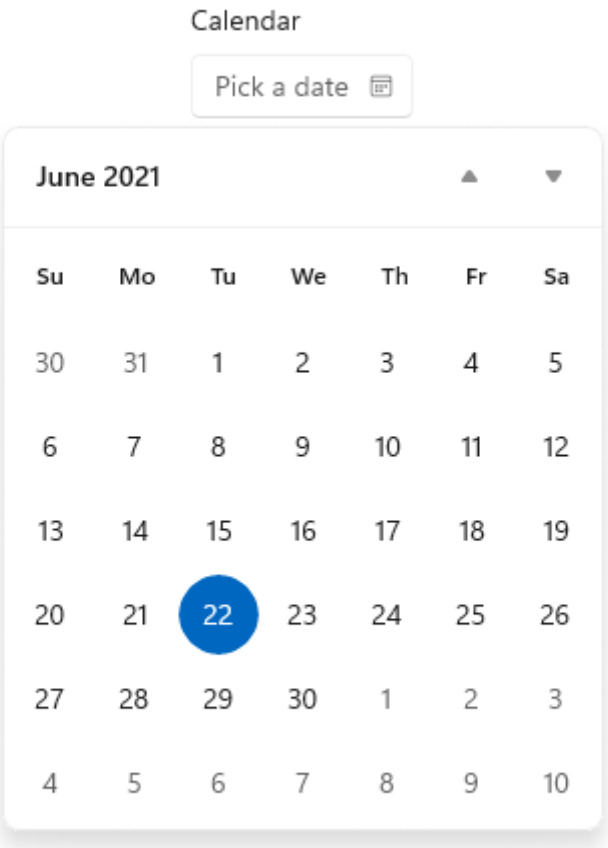
Use a **calendar date picker** to let a user pick a single date from a contextual calendar view. Use it for things like choosing an appointment or departure date.

To let a user pick a known date, such as a date of birth, where the context of the calendar is not important, consider using a date picker.

For more info about choosing the right control, see the Date and time controls article.

Examples

The entry point displays placeholder text if a date has not been set; otherwise, it displays the chosen date. When the user selects the entry point, a calendar view expands for the user to make a date selection. The calendar view overlays other UI; it doesn't push other UI out of the way.



Create a calendar date picker

✓ **Important APIs:** CalendarDatePicker class, Date property, DateChanged event

Open the WinUI 3 Gallery app and see the CalendarDatePicker in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

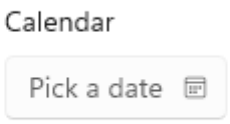
XAML

```
<CalendarDatePicker x:Name="arrivalCalendarDatePicker" Header="Calendar"/>
```

C#

```
CalendarDatePicker arrivalCalendarDatePicker = new CalendarDatePicker();
arrivalCalendarDatePicker.Header = "Calendar";
```

The resulting calendar date picker looks like this:



The calendar date picker has an internal CalendarView for picking a date. A subset of CalendarView properties, like IsTodayHighlighted and FirstDayOfWeek, exist on CalendarDatePicker and are forwarded to the internal CalendarView to let you modify it.

However, you can't change the SelectionMode of the internal CalendarView to allow multiple selection. If you need to let a user pick multiple dates or need a calendar to be always visible, consider using a calendar view instead of a calendar date picker. See the Calendar view article for more info on how you can modify the calendar display.

Selecting dates

Use the Date property to get or set the selected date. By default, the Date property is **null**. When a user selects a date in the calendar view, this property is updated. A user can clear the date by clicking the selected date in the calendar view to deselect it.

You can set the date in your code like this.

```
C#

myCalendarDatePicker.Date = new DateTime(1977, 1, 5);
```

When you set the Date in code, the value is constrained by the MinDate and MaxDate properties.

- If **Date** is smaller than **MinDate**, the value is set to **MinDate**.
- If **Date** is greater than **MaxDate**, the value is set to **MaxDate**.

You can handle the DateChanged event to be notified when the Date value has changed.

> **Note**
>
> For important info about date values, see DateTime and Calendar values in the Date and time controls article.

Setting a header and placeholder text

You can add a Header (or label) and PlaceholderText (or watermark) to the calendar date picker to give the user an indication of what it's used for. To customize the look of the header, you can set the HeaderTemplate property instead of Header.

The default placeholder text is "select a date". You can remove this by setting the PlaceholderText property to an empty string, or you can provide custom text as shown here.

XAML

```
<CalendarDatePicker x:Name="arrivalCalendarDatePicker" Header="Arrival date"
                    PlaceholderText="Choose your arrival date"/>
```

UWP and WinUI 2

> **Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

APIs for this control exist in the Windows.UI.Xaml.Controls namespace.

- ✓ **UWP APIs:** CalendarDatePicker class, Date property, DateChanged event
- ✓ Open the WinUI 2 Gallery app and see the CalendarDatePicker in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles and templates for all controls. WinUI 2.2 or later includes a new template for this control that uses rounded corners. For more info, see Corner radius.

Calendar view

Article • 02/26/2025

A calendar view lets a user view and interact with a calendar that they can navigate by month, year, or decade. A user can select a single date or a range of dates. It doesn't have a picker surface and the calendar is always visible.

Is this the right control?

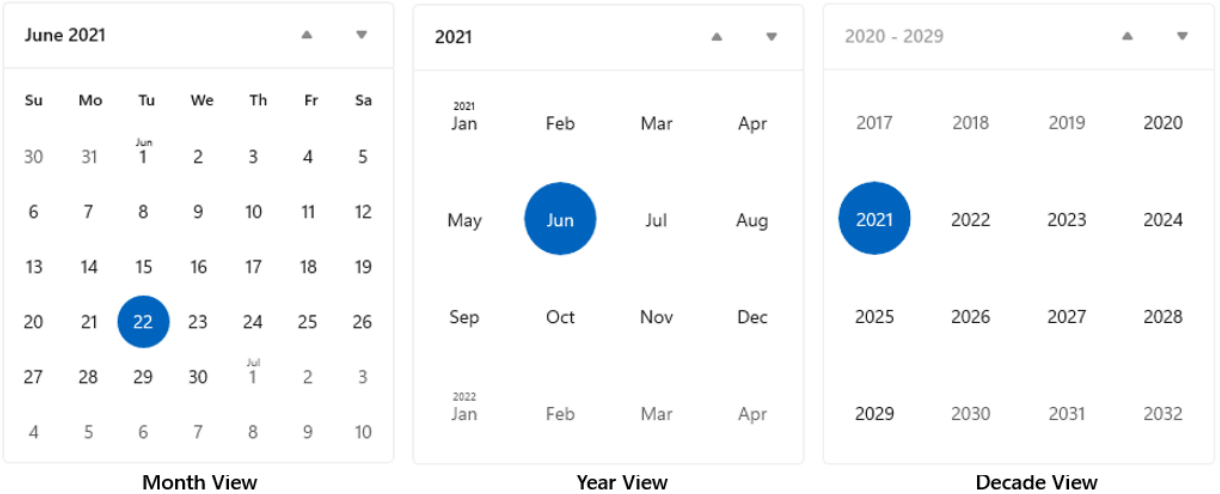
Use a calendar view to let a user pick a single date or a range of dates from an always visible calendar.

If you need to let a user select multiple dates at one time, you must use a calendar view. If you need to let a user pick only a single date and don't need a calendar to be always visible, consider using a calendar date picker or date picker control.

For more info about choosing the right control, see the Date and time controls article.

Examples

The calendar view is made up of 3 separate views: the month view, year view, and decade view. By default, it starts with the month view open. You can specify a startup view by setting the DisplayMode property.



Month View | Year View | Decade View

Users click the header in the month view to open the year view, and click the header in the year view to open the decade view. Users pick a year in the decade view to return to the year view, and pick a month in the year view to return to the month view. The two arrows to the side of the header navigate forward or backward by month, by year, or by decade.

Create a calendar view

✔ **Important APIs:** CalendarView class, SelectedDatesChanged event

Open the WinUI 3 Gallery app and see the CalendarView in action

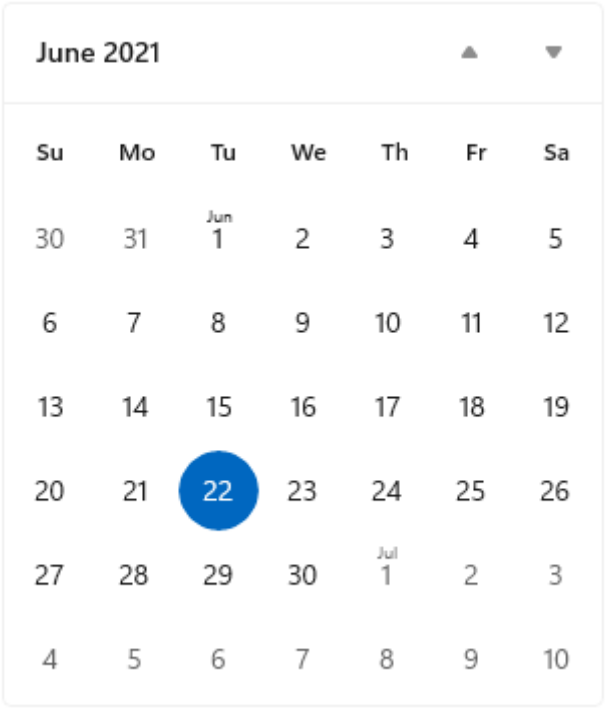
> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

This example shows how to create a simple calendar view.

XAML

```
<CalendarView/>
```

The resulting calendar view looks like this:



Selecting dates

By default, the SelectionMode property is set to **Single**. This lets a user pick a single date in the calendar. Set SelectionMode to **None** to disable date selection.

Set SelectionMode to **Multiple** to let a user select multiple dates. You can select multiple dates programmatically by adding DateTime/DateTimeOffset objects to the

SelectedDates collection, as shown here:

```
C#

calendarView1.SelectedDates.Add(DateTimeOffset.Now);
calendarView1.SelectedDates.Add(new DateTime(1977, 1, 5));
```

A user can deselect a selected date by clicking or tapping it in the calendar grid.

You can handle the SelectedDatesChanged event to be notified when the SelectedDates collection has changed.

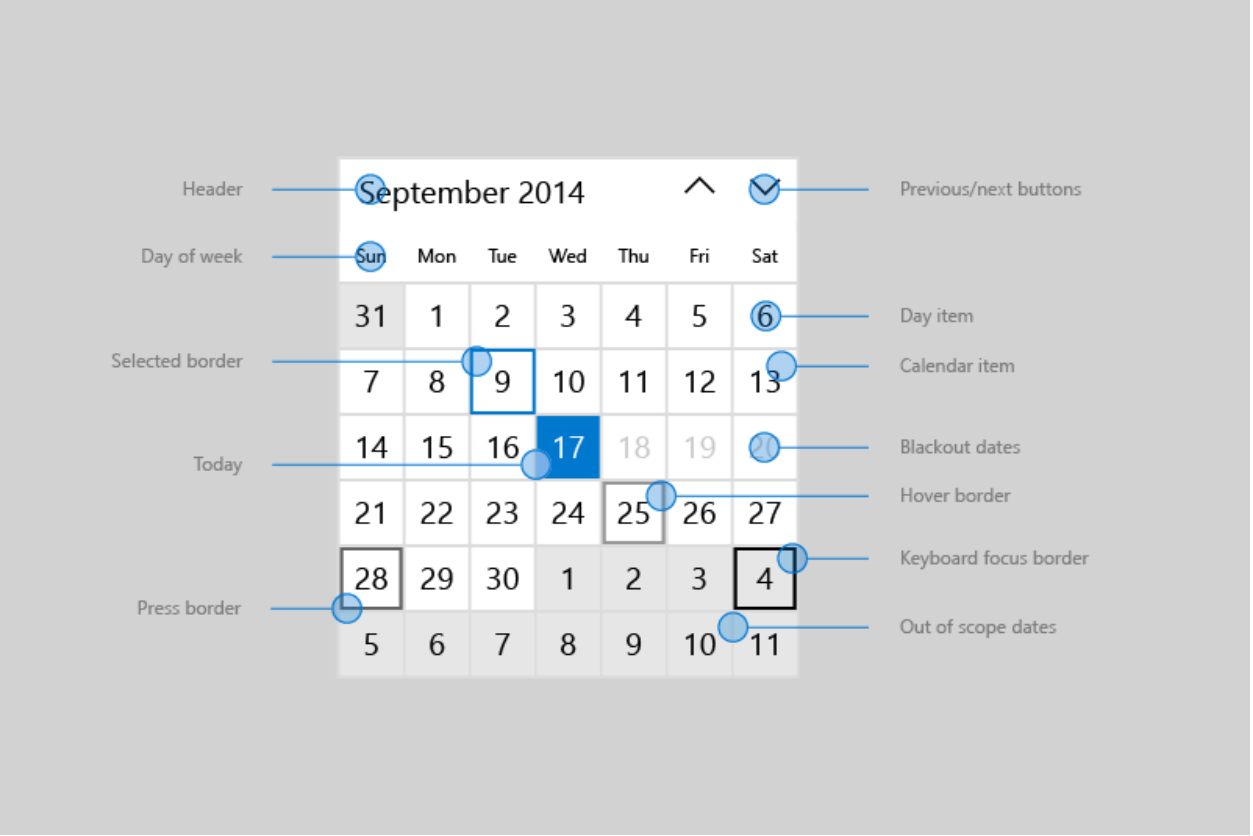
> **Note**
>
> For important info about date values, see **DateTime and Calendar values** in the Date and time controls article.

Customizing the calendar view's appearance

The calendar view is composed of both XAML elements defined in the ControlTemplate and visual elements rendered directly by the control.

- The XAML elements defined in the control template include the border that encloses the control, the header, previous and next buttons, and DayOfWeek elements. You can style and re-template these elements like any XAML control.
- The calendar grid is composed of CalendarViewDayItem objects. You can't style or re-template these elements, but various properties are provided to let you to customize their appearance.

This diagram shows the elements that make up the month view of the calendar. For more info, see the Remarks on the CalendarViewDayItem class.



This table lists the properties you can change to modify the appearance of calendar elements.

Expand table

Element	Properties
DayOfWeek	DayOfWeekFormat
CalendarItem	CalendarItemBackground, CalendarItemBorderBrush, CalendarItemBorderThickness, CalendarItemForeground
DayItem	DayItemFontFamily, DayItemFontSize, DayItemFontStyle, DayItemFontWeight, HorizontalDayItemAlignment, VerticalDayItemAlignment, CalendarViewDayItemStyle
MonthYearItem (in the year and decade views, equivalent to DayItem)	MonthYearItemFontFamily, MonthYearItemFontSize, MonthYearItemFontStyle, MonthYearItemFontWeight
FirstOfMonthLabel	FirstOfMonthLabelFontFamily, FirstOfMonthLabelFontSize, FirstOfMonthLabelFontStyle, FirstOfMonthLabelFontWeight, HorizontalFirstOfMonthLabelAlignment, VerticalFirstOfMonthLabelAlignment, IsGroupLabelVisible
FirstofYearDecadeLabel (in the year and decade views,	FirstOfYearDecadeLabelFontFamily, FirstOfYearDecadeLabelFontSize,

Element	Properties
equivalent to FirstOfMonthLabel)	FirstOfYearDecadeLabelFontStyle, FirstOfYearDecadeLabelFontWeight
Visual State Borders	FocusBorderBrush, HoverBorderBrush, PressedBorderBrush, SelectedBorderBrush, SelectedForeground, SelectedHoverBorderBrush, SelectedPressedBorderBrush
OutofScope	IsOutOfScopeEnabled, OutOfScopeBackground, OutOfScopeForeground
Today	IsTodayHighlighted, TodayFontWeight, TodayForeground

By default, the month view shows 6 weeks at a time. You can change the number of weeks shown by setting the NumberOfWeeksInView property. The minimum number of weeks to show is 2; the maximum is 8.

By default, the year and decade views show in a 4x4 grid. To change the number of rows or columns, call SetYearDecadeDisplayDimensions with the your desired number of rows and columns. This will change the grid for both the year and decade views.

Here, the year and decade views are set to show in a 3x4 grid.

C#

```
calendarView1.SetYearDecadeDisplayDimensions(3, 4);
```

By default, the minimum date shown in the calendar view is 100 years prior to the current date, and the maximum date shown is 100 years past the current date. You can change the minimum and maximum dates that the calendar shows by setting the MinDate and MaxDate properties.

C#

```
calendarView1.MinDate = new DateTime(2000, 1, 1);
calendarView1.MaxDate = new DateTime(2099, 12, 31);
```

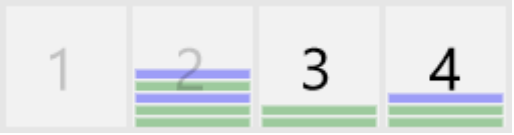
Updating calendar day items

Each day in the calendar is represented by a CalendarViewDayItem object. To access an individual day item and use its properties and methods, handle the CalendarViewDayItemChanging event and use the Item property of the event args to access the CalendarViewDayItem.

You can make a day not selectable in the calendar view by setting its CalendarViewDayItem.IsBlackout property to **true**.

You can show contextual information about the density of events in a day by calling the CalendarViewDayItem.SetDensityColors method. You can show from 0 to 10 density bars for each day, and set the color of each bar.

Here are some day items in a calendar. Days 1 and 2 are blacked out. Days 2, 3, and 4 have various density bars set.



Phased rendering

A calendar view can contain a large number of CalendarViewDayItem objects. To keep the UI responsive and enable smooth navigation through the calendar, calendar view supports phased rendering. This lets you break up processing of a day item into phases. If a day is moved out of view before all the phases are complete, no more time is used trying to process and render that item.

This example shows phased rendering of a calendar view for scheduling appointments.

- In phase 0, the default day item is rendered.
- In phase 1, you blackout dates that can't be booked. This includes past dates, Sundays, and dates that are already fully booked.
- In phase 2, you check each appointment that's booked for the day. You show a green density bar for each confirmed appointment and a blue density bar for each tentative appointment.

The `Bookings` class in this example is from a fictitious appointment booking app, and is not shown.

XAML

```
<CalendarView
CalendarViewDayItemChanging="CalendarView_CalendarViewDayItemChanging"/>
```

C#

```
private void CalendarView_CalendarViewDayItemChanging(CalendarView sender,
                                      CalendarViewDayItemChangingEventArgs
args)
{
```

```
    // Render basic day items.
    if (args.Phase == 0)
    {
        // Register callback for next phase.

args.RegisterUpdateCallback(CalendarView_CalendarViewDayItemChanging);
    }
    // Set blackout dates.
    else if (args.Phase == 1)
    {
        // Blackout dates in the past, Sundays, and dates that are fully
booked.
        if (args.Item.Date < DateTimeOffset.Now ||
            args.Item.Date.DayOfWeek == DayOfWeek.Sunday ||
            Bookings.HasOpenings(args.Item.Date) == false)
        {
            args.Item.IsBlackout = true;
        }
        // Register callback for next phase.

args.RegisterUpdateCallback(CalendarView_CalendarViewDayItemChanging);
    }
    // Set density bars.
    else if (args.Phase == 2)
    {
        // Avoid unnecessary processing.
        // You don't need to set bars on past dates or Sundays.
        if (args.Item.Date > DateTimeOffset.Now &&
            args.Item.Date.DayOfWeek != DayOfWeek.Sunday)
        {
            // Get bookings for the date being rendered.
            var currentBookings = Bookings.GetBookings(args.Item.Date);

            List<Color> densityColors = new List<Color>();
            // Set a density bar color for each of the days bookings.
            // It's assumed that there can't be more than 10 bookings in a
day. Otherwise,
            // further processing is needed to fit within the max of 10
density bars.
            foreach (booking in currentBookings)
            {
                if (booking.IsConfirmed == true)
                {
                    densityColors.Add(Colors.Green);
                }
                else
                {
                    densityColors.Add(Colors.Blue);
                }
            }
            args.Item.SetDensityColors(densityColors);
        }
    }
}
```

Date picker

Article • 02/26/2025

The date picker gives you a standardized way to let users pick a localized date value using touch, mouse, or keyboard input.

Is this the right control?

Use a date picker to let a user pick a known date, such as a date of birth, where the context of the calendar is not important.

If the context of a calendar is important, consider using a calendar date picker or calendar view.

For more info about choosing the right date control, see the Date and time controls article.

Examples

The entry point displays the chosen date, and when the user selects the entry point, a picker surface expands vertically from the middle for the user to make a selection. The date picker overlays other UI; it doesn't push other UI out of the way.

Create a date picker

✓ **Important APIs:** DatePicker class, SelectedDate property

Open the WinUI 3 Gallery app and see the DatePicker in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

This example shows how to create a simple date picker with a header.

XAML

```
<DatePicker x:Name="exampleDatePicker" Header="Pick a date"/>
```

C#

```
DatePicker exampleDatePicker = new DatePicker();
```

```
exampleDatePicker.Header = "Pick a date";
```

The resulting date picker looks like this:

Formatting the date picker

By default, the date picker shows the day, month, and year. If your scenario for the date picker doesn't require all the fields, you can hide the ones you don't need. To hide a field, set its corresponding *field*Visible property to `false`: DayVisible, MonthVisible, or YearVisible.

Here, only the year is needed, so the day and month fields are hidden.

XAML

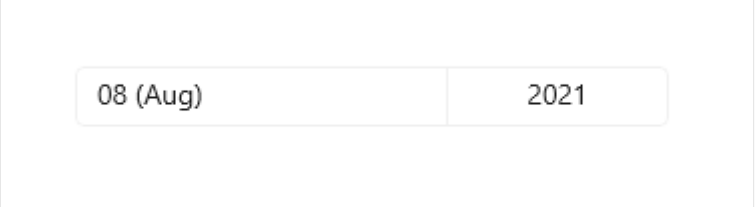
```
<DatePicker x:Name="yearDatePicker" Header="In what year was Microsoft
founded?"
            MonthVisible="False" DayVisible="False"/>
```

The string content of each `ComboBox` in the `DatePicker` is created by a DateTimeFormatter. You inform the `DateTimeFormatter` how to format the date value by providing a string that is either a *format template* or a *format pattern*. For more info, see the DayFormat, MonthFormat, and YearFormat properties.

Here, a *format pattern* is used to show the month as an integer and abbreviation. You can add literal strings to the format pattern, such as the parentheses around the month abbreviation: `({month.abbreviated})`.

XAML

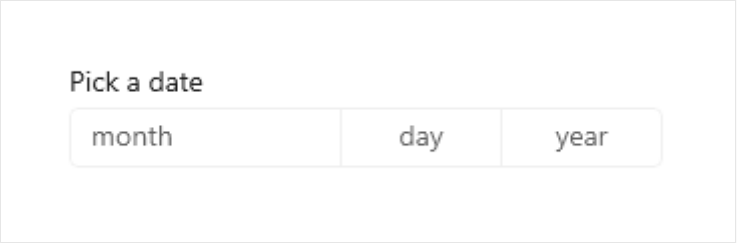
```
<DatePicker MonthFormat="{}{month.integer(2)} ({month.abbreviated})"
DayVisible="False"/>
```



Date values

The date picker control has both Date/DateChanged and SelectedDate/SelectedDateChanged APIs. The difference between these is that `Date` is not nullable, while `SelectedDate` is nullable.

The value of `SelectedDate` is used to populate the date picker and is `null` by default. If `SelectedDate` is `null`, the `Date` property is set to 12/31/1600; otherwise, the `Date` value is synchronized with the `SelectedDate` value. When `SelectedDate` is `null`, the picker is 'unset' and shows the field names instead of a date.



You can set the MinYear and MaxYear properties to restrict the date values in the picker. By default, `MinYear` is set to 100 years prior to the current date and `MaxYear` is set to 100 years past the current date.

If you set only `MinYear` or `MaxYear`, you need to ensure that a valid date range is created by the date you set and the default value of the other date; otherwise, no date will be available to select in the picker. For example, setting only `yearDatePicker.MaxYear = new DateTimeOffset(new DateTime(900, 1, 1));` creates an invalid date range with the default value of `MinYear`.

Initializing a date value

The date properties can't be set as a XAML attribute string, because the Windows Runtime XAML parser doesn't have a conversion logic for converting strings to dates as

DateTime / DateTimeOffset objects. Here are some suggested ways these objects can be defined in code and set to a date other than the current date.

- DateTime: Instantiate a Windows.Globalization.Calendar object (it is initialized to the current date). Set Year, or call AddYears, to adjust the date. Then, call Calendar.GetDateTime and use the returned `DateTime` to set the date property.
- DateTimeOffset: Call the constructor. For the inner System.DateTime, use the constructor signature. Or, construct a default DateTimeOffset (it is initialized to the current date) and call AddYears.

Another possible technique is to define a date that's available as a data object or in the data context, then set the date property as a XAML attribute that references a {Binding} markup extension that can access the date as data.

> ⓘ **Note**
>
> For important info about date values, see **DateTime and Calendar values** in the Date and time controls article.

This example demonstrates setting the `SelectedDate`, `MinYear`, and `MaxYear` properties on different `DatePicker` controls.

XAML

```
<DatePicker x:Name="yearDatePicker" MonthVisible="False"
DayVisible="False"/>
<DatePicker x:Name="arrivalDatePicker" Header="Arrival date"/>
```

C#

```
public MainPage()
{
    this.InitializeComponent();

    // Set minimum year to 1900 and maximum year to 1999.
    yearDatePicker.SelectedDate = new DateTimeOffset(new DateTime(1950, 1,
1));
    yearDatePicker.MinYear = new DateTimeOffset(new DateTime(1900, 1, 1));
    // Using a different DateTimeOffset constructor.
    yearDatePicker.MaxYear = new DateTimeOffset(1999, 12, 31, 0, 0, 0, new
TimeSpan());

    // Set minimum to the current year and maximum to five years from now.
    arrivalDatePicker.MinYear = DateTimeOffset.Now;
```

```
    arrivalDatePicker.MaxYear = DateTimeOffset.Now.AddYears(5);
}
```

Using the date values

To use the date value in your app, you typically use a data binding to the SelectedDate property, or handle the SelectedDateChanged event.

> For an example of using a `DatePicker` and `TimePicker` together to update a single `DateTime` value, see Calendar, date, and time controls - Use a date picker and time picker together.

Here, you use a `DatePicker` to let a user select their arrival date. You handle the `SelectedDateChanged` event to update a DateTime instance named `arrivalDateTime`.

XAML

```
<StackPanel>
    <DatePicker x:Name="arrivalDatePicker" Header="Arrival date"
                DayFormat="{}{day.integer} ({dayofweek.abbreviated})"

SelectedDateChanged="arrivalDatePicker_SelectedDateChanged"/>
    <Button Content="Clear" Click="ClearDateButton_Click"/>
    <TextBlock x:Name="arrivalText" Margin="0,12"/>
</StackPanel>
```

C#

```
public sealed partial class MainPage : Page
{
    DateTime arrivalDateTime;

    public MainPage()
    {
        this.InitializeComponent();

        // Set minimum to the current year and maximum to five years from
now.
        arrivalDatePicker.MinYear = DateTimeOffset.Now;
        arrivalDatePicker.MaxYear = DateTimeOffset.Now.AddYears(5);
    }

    private void arrivalDatePicker_SelectedDateChanged(DatePicker sender,
DatePickerSelectedValueChangedEventArgs args)
    {
        if (arrivalDatePicker.SelectedDate != null)
        {
```

```
            arrivalDateTime = new DateTime(args.NewDate.Value.Year,
args.NewDate.Value.Month, args.NewDate.Value.Day);
        }
        arrivalText.Text = arrivalDateTime.ToString();
    }

    private void ClearDateButton_Click(object sender, RoutedEventArgs e)
    {
        arrivalDatePicker.SelectedDate = null;
        arrivalText.Text = string.Empty;
    }
}
```

UWP and WinUI 2

> **ⓘ Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

APIs for this control exist in the Windows.UI.Xaml.Controls namespace.

- ✓ **UWP APIs:** DatePicker class, SelectedDate property
- ✓ Open the WinUI 2 Gallery app and see the DatePicker in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles and templates for all controls. WinUI 2.2 or later includes a new template for this control that uses rounded corners. For more info, see Corner radius.

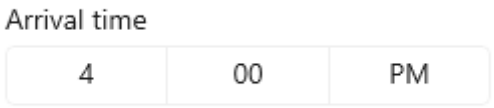
Time picker

Article • 02/26/2025

The time picker gives you a standardized way to let users pick a time value using touch, mouse, or keyboard input.



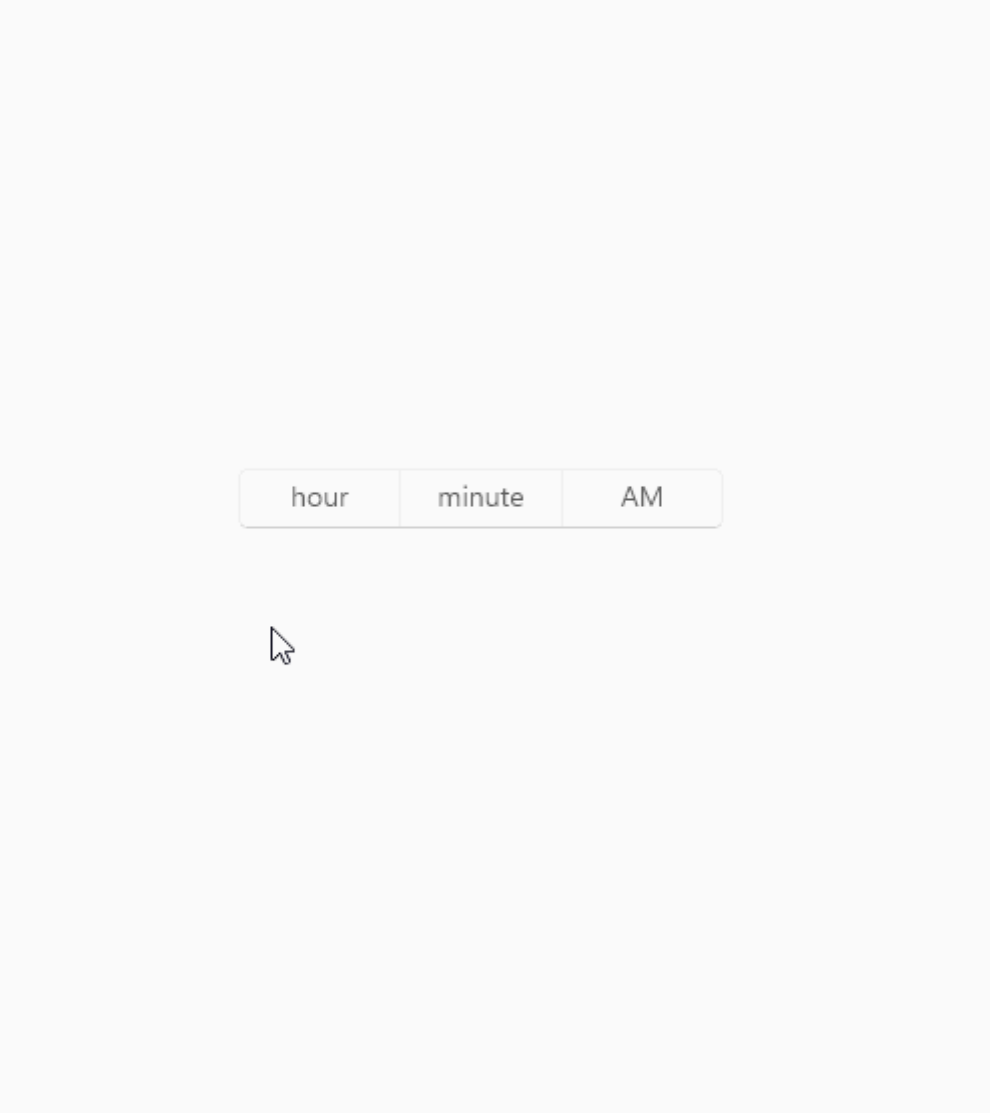
Is this the right control?

Use a time picker to let a user pick a single time value.

For more info about choosing the right control, see the Date and time controls article.

Examples

The entry point displays the chosen time, and when the user selects the entry point, a picker surface expands vertically from the middle for the user to make a selection. The time picker overlays other UI; it doesn't push other UI out of the way.



Create a time picker

✔ **Important APIs:** TimePicker class, SelectedTime property

Open the WinUI 3 Gallery app and see the TimePicker in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

This example shows how to create a simple time picker with a header.

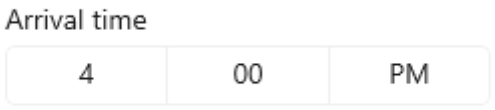
XAML

```
<TimePicker x:Name="arrivalTimePicker" Header="Arrival time"/>
```

C#

```
TimePicker arrivalTimePicker = new TimePicker();
arrivalTimePicker.Header = "Arrival time";
```

The resulting time picker looks like this:



Formatting the time picker

By default, the time picker shows a 12-hour clock with an AM/PM selector. You can set the ClockIdentifier property to "24HourClock" to show a 24-hour clock instead.

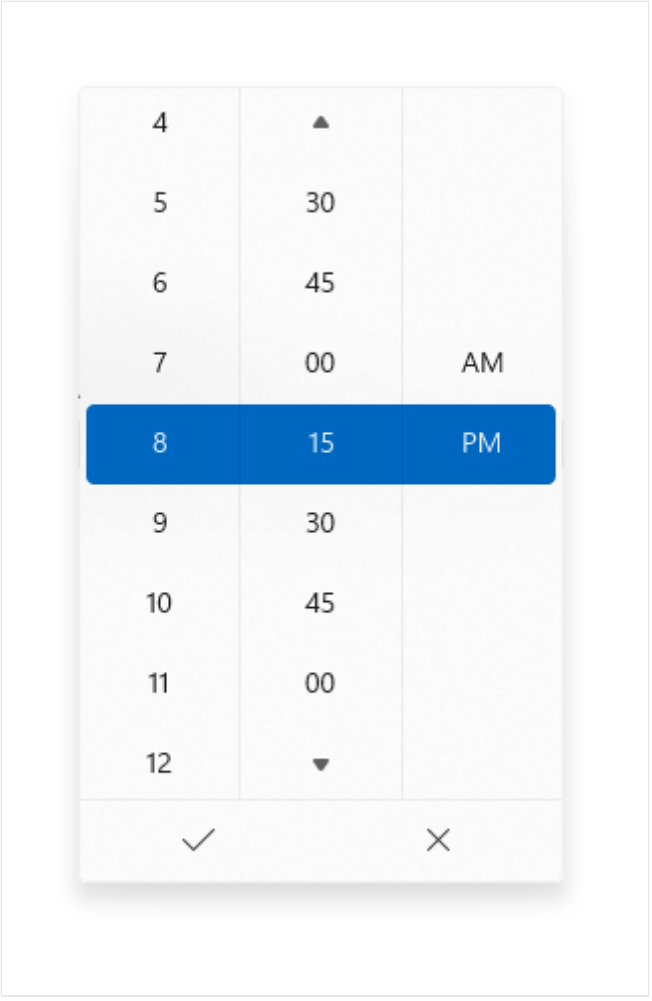
XAML

```
<TimePicker Header="24HourClock" SelectedTime="18:21"
ClockIdentifier="24HourClock"/>
```

You can set the MinuteIncrement property to indicate the time increments shown in the minute picker. For example, 15 specifies that the `TimePicker` minute control displays only the choices 00, 15, 30, 45.

XAML

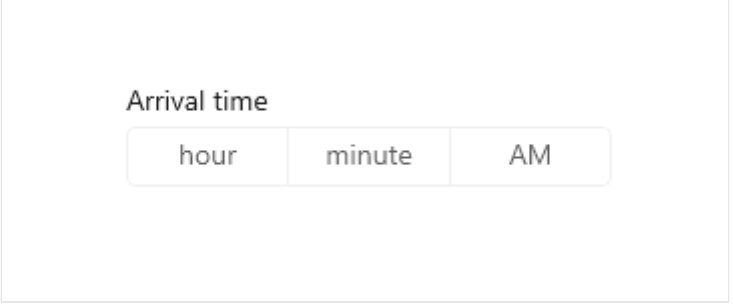
```
<TimePicker MinuteIncrement="15"/>
```



Time values

The time picker control has both Time/TimeChanged and SelectedTime/SelectedTimeChanged APIs. The difference between these is that `Time` is not nullable, while `SelectedTime` is nullable.

The value of `SelectedTime` is used to populate the time picker and is `null` by default. If `SelectedTime` is `null`, the `Time` property is set to a TimeSpan of 0; otherwise, the `Time` value is synchronized with the `SelectedTime` value. When `SelectedTime` is `null`, the picker is 'unset' and shows the field names instead of a time.



Initializing a time value

In code, you can initialize the time properties to a value of type `TimeSpan`:

```
C#

TimePicker timePicker = new TimePicker
{
    SelectedTime = new TimeSpan(14, 15, 00) // Seconds are ignored.
};
```

You can set the time value as an attribute in XAML. This is probably easiest if you're already declaring the `TimePicker` object in XAML and aren't using bindings for the time value. Use a string in the form *Hh:Mm* where *Hh* is hours and can be between 0 and 23 and *Mm* is minutes and can be between 0 and 59.

```
XAML

<TimePicker SelectedTime="14:15"/>
```

> **Note**
>
> For important info about date and time values, see DateTime and Calendar values in the *Date and time controls* article.

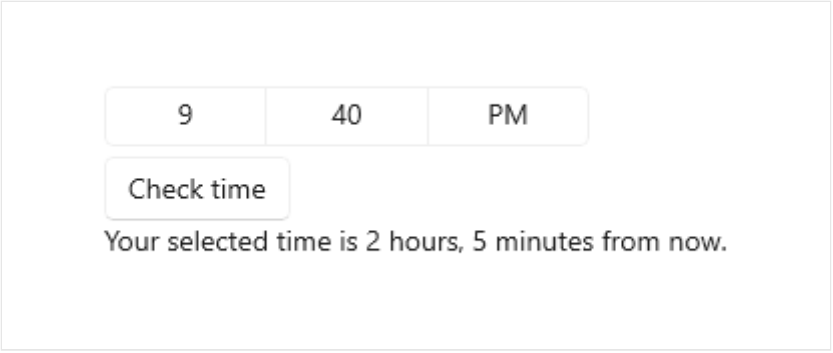
Using the time values

To use the time value in your app, you typically use a data binding to the SelectedTime or Time property, use the time properties directly in your code, or handle the SelectedTimeChanged or TimeChanged event.

> For an example of using a `DatePicker` and `TimePicker` together to update a single `DateTime` value, see Calendar, date, and time controls - Use a date picker and time picker together.

Here, the `SelectedTime` property is used to compare the selected time to the current time.

Notice that because the `SelectedTime` property is nullable, you have to explicitly cast it to `DateTime`, like this: `DateTime myTime = (DateTime)(DateTime.Today + checkTimePicker.SelectedTime);`. The `Time` property, however, could be used without a cast, like this: `DateTime myTime = DateTime.Today + checkTimePicker.Time;`.



XAML

```
<StackPanel>
    <TimePicker x:Name="checkTimePicker"/>
    <Button Content="Check time" Click="{x:Bind CheckTime}"/>
    <TextBlock x:Name="resultText"/>
</StackPanel>
```

C#

```
private void CheckTime()
{
    // Using the Time property.
    // DateTime myTime = DateTime.Today + checkTimePicker.Time;
    // Using the SelectedTime property (nullable requires cast to DateTime).
    DateTime myTime = (DateTime)(DateTime.Today +
checkTimePicker.SelectedTime);
    if (DateTime.Now >= myTime)
    {
        resultText.Text = "Your selected time has already past.";
    }
    else
    {
        string hrs = (myTime - DateTime.Now).Hours.ToString();
        string mins = (myTime - DateTime.Now).Minutes.ToString();
        resultText.Text = string.Format("Your selected time is {0} hours,
{1} minutes from now.", hrs, mins);
    }
}
```

UWP and WinUI 2

ⓘ Important

The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.

This section contains information you need to use the control in a UWP or WinUI 2 app.

APIs for this control exist in the Windows.UI.Xaml.Controls namespace.

- ✓ **UWP APIs:** TimePicker class, SelectedTime property
- ✓ Open the WinUI 2 Gallery app and see the TimePicker in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles and templates for all controls. WinUI 2.2 or later includes a new template for this control that uses rounded corners. For more info, see Corner radius.

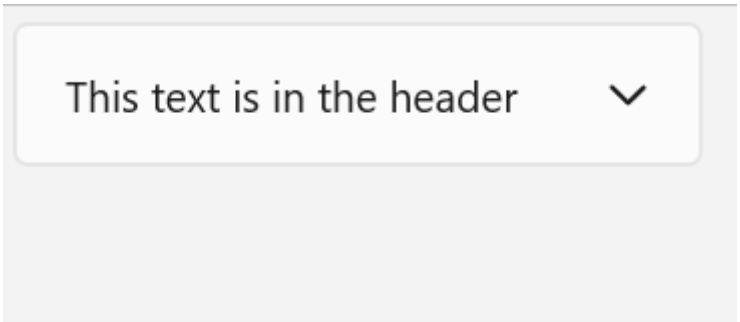
Expander

Article • 02/26/2025

The Expander control lets you show or hide less important content that's related to a piece of primary content that's always visible. Items contained in the Header are always visible. The user can expand and collapse the Content area, where secondary content is displayed, by interacting with the header. When the content area is expanded, it pushes other UI elements out of the way; it does not overlay other UI. The `Expander` can expand upwards or downwards.

Both the `Header` and `Content` areas can contain any content, from simple text to complex UI layouts. For example, you can use the control to show additional options for an item.



Is this the right control?

Use an `Expander` when some primary content should always be visible, but related secondary content may be hidden until needed. This UI is commonly used when display space is limited and when information or options can be grouped together. Hiding the secondary content until it's needed can also help to focus the user on the most important parts of your app.

Create an Expander

✓ **Important APIs:** Expander class, Header property, Content property

Open the WinUI 3 Gallery app and see the Expander in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

This example shows how to create a simple Expander with the default styling. The Header property defines the element that is always visible. The Content property defines the element that can be collapsed and expanded. This example creates an `Expander` that looks like the previous illustration.

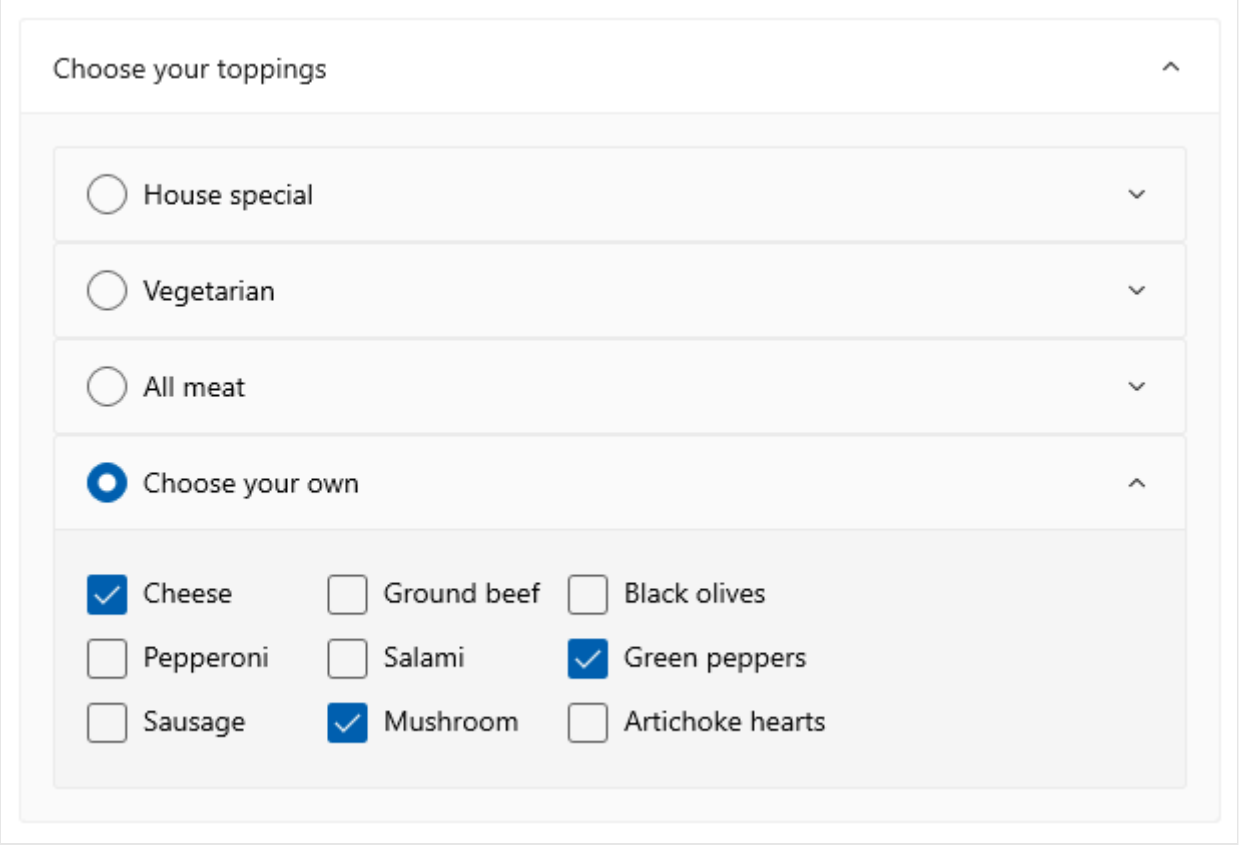
XAML

```
<Expander Header="This text is in the header"
                Content="This is in the content"/>
```

Expander content

The Content property of an `Expander` can be any type of object, but is typically a string or UIElement. For more details about setting the `Content` property, see the Remarks section of the ContentControl class.

You can use complex, interactive UI as the content of the `Expander`, including nested `Expander` controls in the content of a parent `Expander` as shown here.



Content alignment

You can align content by setting the HorizontalContentAlignment and VerticalContentAlignment properties on the `Expander` control. When you set these

properties, the alignment applies only to the expanded content, not the header.

Control the size of an Expander

By default, the Header and Content areas automatically size to fit their contents. It's important to use the correct techniques to control the size of the `Expander` to avoid undesirable appearance or behavior.

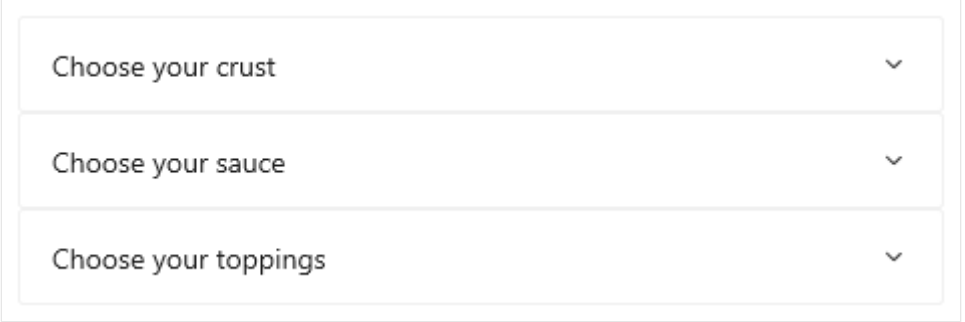
Width

If the content is wider than the header, the header width increases to match the content area when expanded, and shrinks when the content area is collapsed. To prevent the control width from changing when expanded or collapsed, you can set an explicit width, or, if the control is the child of a Panel, set HorizontalAlignment to Stretch and let the layout panel control the sizing.

Here, a series of related `Expander` controls are placed in a StackPanel. The `HorizontalAlignment` of each `Expander` in the `StackPanel` is set to `Stretch` using a Style in the `StackPanel` Resources, and the width of the `StackPanel` determines the width of the `Expander` controls.

XAML

```
<StackPanel x:Name="ExpanderStack" MaxWidth="600">
    <StackPanel.Resources>
        <Style TargetType="Expander">
            <Setter Property="HorizontalAlignment" Value="Stretch"/>
            <Setter Property="HorizontalContentAlignment" Value="Stretch"/>
        </Style>
    </StackPanel.Resources>
    <Expander Header="Choose your crust"> ... </Expander>
    <Expander Header="Choose your sauce"> ... </Expander>
    <Expander Header="Choose your toppings"> ... </Expander>
 </StackPanel>
```



Height

Do not specify a Height on the `Expander`. If you do, the control will reserve that space even when the content area is collapsed, which defeats the purpose of the `Expander`. To specify the size of the expanded content area, set size dimensions on the content of the `Expander`. If you need to, you can constrain the `Height` of the content and make the content scrollable.

Scrollable content

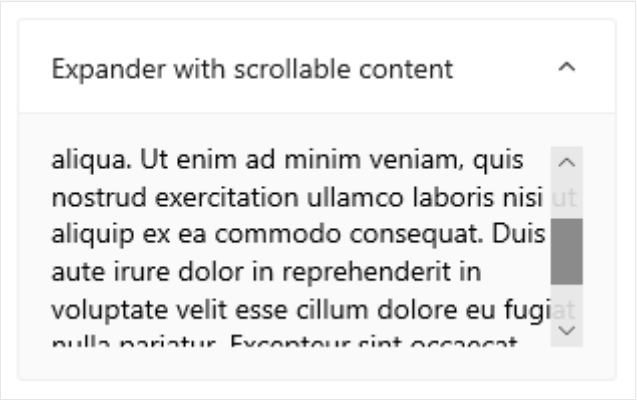
If your content is too large for the size of the content area, you can wrap the content a ScrollViewer to make the content area scrollable. The `Expander` control does not automatically provide scrolling capability.

When you place a `ScrollViewer` in the `Expander` content, set the height on the `ScrollViewer` control to the required height for the content area. If you instead set the height dimension on the content inside the `ScrollViewer`, `ScrollViewer` doesn't recognize this setting and therefore does not provide scrollable content.

The following example shows how to create an `Expander` control that contains scrollable text as its content.

XAML

```
<Expander Header="Expander with scrollable content">
    <ScrollViewer MaxHeight="200">
        <Grid>
            <TextBlock TextWrapping="Wrap">
                Lorem ipsum dolor sit amet, consectetur adipisicing elit,
                sed do eiusmod tempor incididunt ut labore et dolore magna
                aliqua. Ut enim ad minim veniam, quis nostrud exercitation
                ullamco laboris nisi ut aliquip ex ea commodo consequat.
                Duis aute irure dolor in reprehenderit in voluptate velit
                esse cillum dolore eu fugiat nulla pariatur. Excepteur sint
                occaecat cupidatat non proident, sunt in culpa qui officia
                deserunt mollit anim id est laborum.
            </TextBlock>
        </Grid>
    </ScrollViewer>
</Expander>
```



Expanding and collapsing the content area

By default, the Expander is collapsed and expands downwards.

- Set the IsExpanded property to `true` to have the content area initially expanded.
- Set the ExpandDirection property to Up to make the content expand upward.

XAML

```
<Expander IsExpanded="True" ExpandDirection="Up">
```

An `Expander` is expanded or collapsed either programmatically by setting the `IsExpanded` property, or by interacting with the `Header`; it cannot be light-dismissed.

> **Tip**
>
> Transient UI, such as a `Flyout` or the open drop-down of a `ComboBox`, closes when you click or tap outside of it. This is called *light-dismiss*. The content area of an `Expander` is not considered transient and does not overlay other UI, so it does not support light-dismiss.

You can also handle the Expanding and Collapsed events to take an action when the content is shown or hidden. Here are some examples of these events.

Expanding event

In this example, you have a group of expanders and want to have only one open at a time. When the user opens an `Expander`, you handle the Expanding event and collapse all `Expander` controls in the group other than the one the user clicked.

> **Caution**

Depending on your app and user experience, it might be a convenience to automatically collapse `Expander` controls when the user expands a different one. However, this also takes control away from the user. If the behavior might be useful, consider making it an option that the user can easily set.

XAML

```
<StackPanel x:Name="ExpanderStack">
    <Expander Header="Choose your crust"
                  Expanding="Expander_Expanding"> ... </Expander>
    <Expander Header="Choose your sauce"
                  Expanding="Expander_Expanding"> ... </Expander>
    <Expander Header="Choose your toppings"
                  Expanding="Expander_Expanding"> ... </Expander>
 </StackPanel>
```

C#

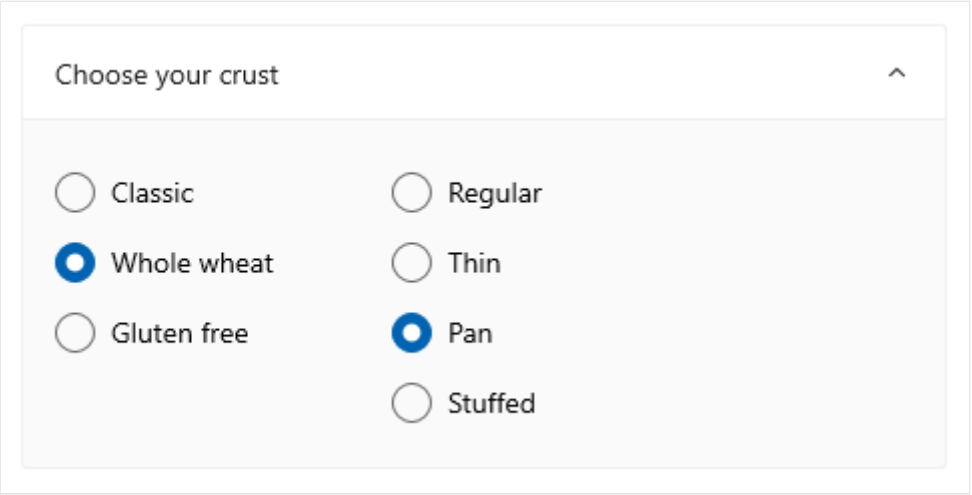
```
// Let the user opt out of custom behavior.
private bool _autoCollapse = true;

private void Expander_Expanding(muxc.Expander sender,
                                muxc.ExpanderExpandingEventArgs args)
{
    if (_autoCollapse == true)
    {
        foreach (muxc.Expander ex in ExpanderStack.Children)
        {
            if (ex != sender && ex.IsExpanded)
                ex.IsExpanded = false;
        }
    }
}
```

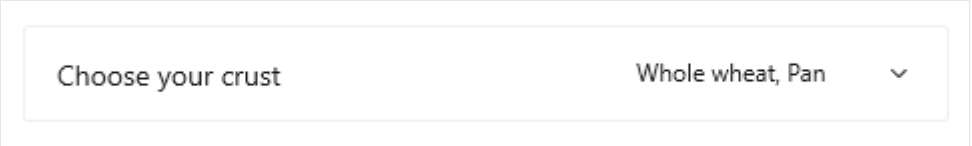
Collapsed event

In this example, you handle the Collapsed event and populate the `Header` with a summary of options that are selected in the `Content`.

This image shows the `Expander` with the content expanded and options selected.



When collapsed, the selected options are summarized in the header so that the user can still see them without opening the `Expander`.



XAML

```
<Expander IsExpanded="True"
        Expanding="Expander_Expanding"
        Collapsed="Expander_Collapsed">
    <Expander.Header>
        <Grid>
            <TextBlock Text="Choose your crust"/>
            <TextBlock x:Name="tbCrustSelections"
                       HorizontalAlignment="Right"
                       Style="{StaticResource CaptionTextBlockStyle}"/>
        </Grid>
    </Expander.Header>
    <StackPanel Orientation="Horizontal">
        <RadioButtons x:Name="rbCrustType" SelectedIndex="0">
            <x:String>Classic</x:String>
            <x:String>Whole wheat</x:String>
            <x:String>Gluten free</x:String>
        </RadioButtons>
        <RadioButtons x:Name="rbCrustStyle" SelectedIndex="0"
                      Margin="48,0,0,0">
            <x:String>Regular</x:String>
            <x:String>Thin</x:String>
            <x:String>Pan</x:String>
            <x:String>Stuffed</x:String>
        </RadioButtons>
    </StackPanel>
</Expander>
```

C#

```
private void Expander_Collapsed(muxc.Expander sender,
                                muxc.ExpanderCollapsedEventArgs args)
{
    // Update the header with options selected in the content.
    tbCrustSelections.Text = rbCrustType.SelectedItem.ToString() +
        ", " + rbCrustStyle.SelectedItem.ToString();
}
```

Lightweight styling

You can modify the default `Style` and `ControlTemplate` to give the control a unique appearance. See the Control Style and Template section of the Expander API docs for a list of the available theme resources. For more info, see the Light-weight styling section of the Styling controls article.

Recommendations

- Use an `Expander` when display space is limited and some secondary content may be hidden until the user requests it.

Code examples

This XAML creates the group of `Expander` controls shown in other parts of this article. The code for the `Expanding` and `Collapsed` event handlers is also shown in previous sections.

XAML

```
<StackPanel x:Name="ExpanderStack" MaxWidth="600">
    <StackPanel.Resources>
        <Style TargetType="Expander">
            <Setter Property="HorizontalAlignment" Value="Stretch"/>
            <Setter Property="HorizontalContentAlignment" Value="Stretch"/>
        </Style>
    </StackPanel.Resources>
    <Expander IsExpanded="True"
                  Expanding="Expander_Expanding"
                  Collapsed="Expander_Collapsed">
        <Expander.Header>
            <Grid>
                <TextBlock Text="Choose your crust"/>
                <TextBlock x:Name="tbCrustSelections"
                           HorizontalAlignment="Right"
        Style="{StaticResource CaptionTextBlockStyle}"/>
            </Grid>
```

```
        </Expander.Header>
        <StackPanel Orientation="Horizontal">
            <RadioButtons x:Name="rbCrustType" SelectedIndex="0">
                <x:String>Classic</x:String>
                <x:String>Whole wheat</x:String>
                <x:String>Gluten free</x:String>
            </RadioButtons>
            <RadioButtons x:Name="rbCrustStyle" SelectedIndex="0"
                   Margin="48,0,0,0">
                <x:String>Regular</x:String>
                <x:String>Thin</x:String>
                <x:String>Pan</x:String>
                <x:String>Stuffed</x:String>
            </RadioButtons>
        </StackPanel>
    </Expander>

    <Expander Header="Choose your sauce" Margin="24"
            Expanding="Expander_Expanding">
        <RadioButtons SelectedIndex="0" MaxColumns="2">
            <x:String>Classic red</x:String>
            <x:String>Garlic</x:String>
            <x:String>Pesto</x:String>
            <x:String>Barbecue</x:String>
        </RadioButtons>
    </Expander>

    <Expander Header="Choose your toppings"
                    Expanding="Expander_Expanding">
        <StackPanel>
            <Expander>
                <Expander.Header>
                    <RadioButton GroupName="Toppings" Content="House
special"/>
                </Expander.Header>
                <TextBlock Text="Cheese, pepperoni, sausage, black olives,
mushrooms"
                           TextWrapping="WrapWholeWords"/>
            </Expander>
            <Expander>
                <Expander.Header>
                    <RadioButton GroupName="Toppings" Content="Vegetarian"/>
                </Expander.Header>
                <TextBlock Text="Cheese, mushrooms, black olives, green
peppers, artichoke hearts"
                           TextWrapping="WrapWholeWords"/>
            </Expander>
            <Expander>
                <Expander.Header>
                    <RadioButton GroupName="Toppings" Content="All meat"/>
                </Expander.Header>
                <TextBlock Text="Cheese, pepperoni, sausage, ground beef,
salami"
                           TextWrapping="WrapWholeWords"/>
            </Expander>
```

```
            <Expander>
                <Expander.Header>
                    <RadioButton GroupName="Toppings" Content="Choose your
own"/>
                </Expander.Header>
                <StackPanel Orientation="Horizontal">
                    <StackPanel>
                        <CheckBox Content="Cheese"/>
                        <CheckBox Content="Pepperoni"/>
                        <CheckBox Content="Sausage"/>
                    </StackPanel>
                    <StackPanel>
                        <CheckBox Content="Ground beef"/>
                        <CheckBox Content="Salami"/>
                        <CheckBox Content="Mushroom"/>
                    </StackPanel>
                    <StackPanel>
                        <CheckBox Content="Black olives"/>
                        <CheckBox Content="Green peppers"/>
                        <CheckBox Content="Artichoke hearts"/>
                    </StackPanel>
                </StackPanel>
            </Expander>
        </StackPanel>
    </Expander>
</StackPanel>
```

UWP and WinUI 2

> **ⓘ Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

The Expander for UWP apps requires WinUI 2. For more info, including installation instructions, see WinUI 2. APIs for this control exist in the Microsoft.UI.Xaml.Controls namespace.

- ✓ **WinUI 2 Apis:** Expander class, Header property, Content property
- ✓ Open the WinUI 2 Gallery app and see the Expander in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and

functionality. Get the app from the Microsoft Store or get the source code on GitHub.

To use the code in this article with WinUI 2, use an alias in XAML (we use `muxc`) to represent the Windows UI Library APIs that are included in your project. See Get Started with WinUI 2 for more info.

XAML

```
xmlns:muxc="using:Microsoft.UI.Xaml.Controls"

<muxc:Expander />

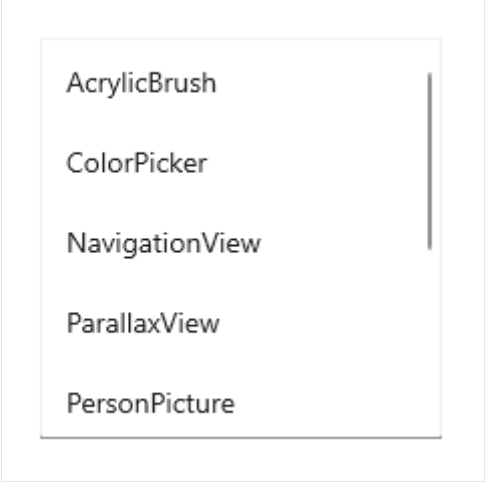
Scroll viewer controls

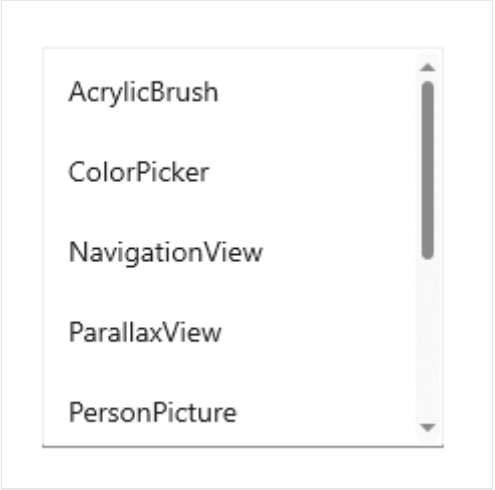
Article • 02/26/2025

When there is more UI content to show than you can fit in an area, use a scroll viewer control.

Scroll viewers enable content to extend beyond the bounds of the viewport (visible area). Users reach this content by manipulating the scroll viewer surface through touch, mousewheel, keyboard, or a gamepad, or by using the mouse or pen cursor to interact with the scroll viewer's scrollbar.

Depending on the situation, the scroll viewer's scrollbar uses two different visualizations, shown in the following illustration: the panning indicator (left) and the traditional scrollbar thumb (right).





ⓘ Important

WinUI 3 has two different scroll viewer controls available: ScrollViewer and ScrollView. Whenever we speak generically about *scroll viewer* controls, the

information applies to both controls.

Scrolling, panning, and zooming

Use a scroll viewer control to allow *scrolling*, *panning*, and *zooming* of your content.

- *Scrolling*: Moving the content vertically or horizontally by dragging the scrollbar thumb or using the scroll wheel on a mouse.
- *Panning*: Moving content vertically or horizontally using touch or pen input.
  - For more info about scrolling and panning, see Guidelines for panning.
- *Zooming*: Optically increasing or decreasing the scale of the content.
  - For more info about zooming, see Optical zoom and resizing.

The scrollbar is conscious of the user's input method and uses it to determine which visualization to display.

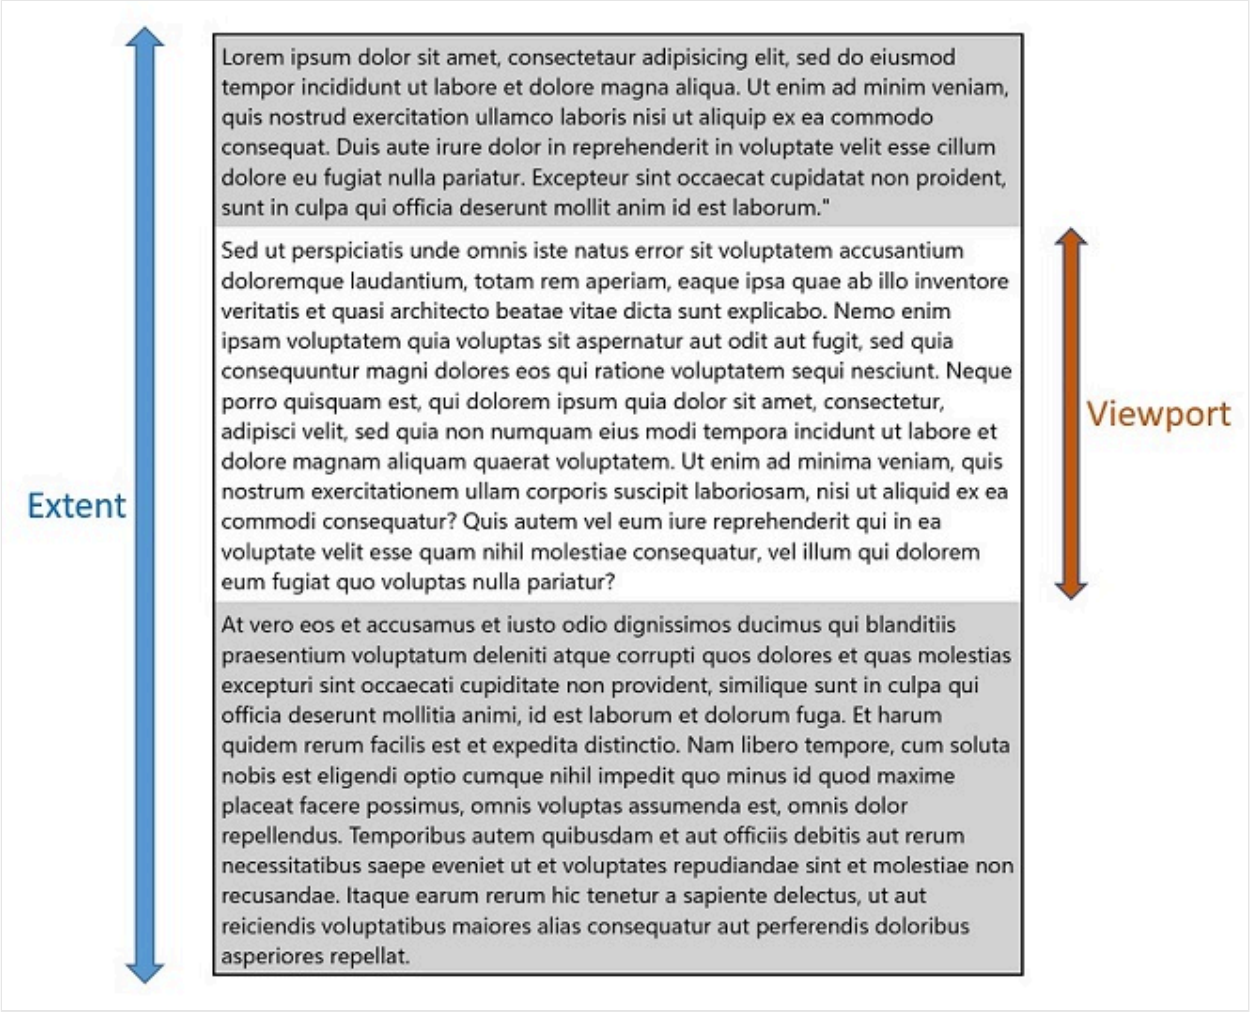
- When the region is scrolled without manipulating the scrollbar directly, for example, by touch, the panning indicator appears, displaying the current scroll position.
- When the mouse or pen cursor moves over the panning indicator, it morphs into the traditional scrollbar. Dragging the scrollbar thumb manipulates the scrolling region.

> **Note**
>
> When the scrollbar is visible it is overlaid as 16px on top of the content inside your ScrollViewer. In order to ensure good UX design you will want to ensure that no interactive content is obscured by this overlay. Additionally if you would prefer not

to have UX overlap, leave 16px of padding on the edge of the viewport to allow for the scrollbar.

Viewport and extent

A scroll viewer is composed of two main regions that are important to understanding its functionality. The area that includes all of the scrollable content, both hidden and visible, is the *extent*. The visible area of the control where the content is shown is the *viewport*.



Various APIs are available that let you get the height and width of these regions, as well as the *scrollable* height and width, which is the difference between the extent size and the viewport size.

Recommendations

- Whenever possible, design for vertical scrolling rather than horizontal.
- Use one-axis panning for content regions that extend beyond one viewport boundary (vertical or horizontal). Use two-axis panning for content regions that extend beyond both viewport boundaries (vertical and horizontal).

- Use the built-in scroll functionality in the items view, list view, grid view, combo box, list box, text input box, and hub controls. With those controls, if there are too many items to show all at once, the user is able to scroll either horizontally or vertically over the list of items.
- If you want the user to pan in both directions around a larger area, and possibly to zoom, too, for example, if you want to allow the user to pan and zoom over a full-sized image (rather than an image sized to fit the screen) then place the image inside a scroll viewer.
- If the user will scroll through a long passage of text, configure the scroll viewer to scroll vertically only.
- Use a scroll viewer to contain one object only. Note that the one object can be a layout panel, in turn containing any number of objects of its own.
- If you need to handle pointer events for a UIElement in a scrollable view (such as a ScrollViewer or ListView), you must explicitly disable support for manipulation events on the element in the view by calling UIElement.CancelDirectManipulation. To re-enable manipulation events in the view, call UIElement.TryStartDirectManipulation.

Create a scroll viewer

✓ **Important APIs:** ScrollView class, ScrollViewer class, ScrollBar class

Open the WinUI 3 Gallery app and see the ScrollView in action

Open the WinUI 3 Gallery app and see the ScrollViewer in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

A scroll viewer control can be used to make content scrollable by explicitly wrapping the content in the scroll viewer, or by placing a scroll viewer in the control template of a content control.

Scroll viewer in a control template

It's typical for a scroll viewer control to exist as a composite part of other controls. A scroll viewer part will display a viewport along with scrollbars only when the host control's layout space is being constrained smaller than the expanded content size.

ItemsView includes a `ScrollView` control in its template. You can access the `ScrollView` though the ItemsView.ScrollView property.

ListView and GridView templates always include a `ScrollViewer`. TextBox and RichEditBox also include a `ScrollViewer` in their templates. To influence some of the behavior and properties of the built in `ScrollViewer` part, `ScrollViewer` defines a number of XAML attached properties that can be set in styles and used in template bindings. For more info about attached properties, see Attached properties overview.

Set scrollable content

Content inside of a scroll viewer becomes scrollable when it's larger than the scroll viewer's viewport

This example sets a `Rectangle` as the content of the `ScrollView` control. The user only sees a 500x400 portion of that rectangle and can scroll to see the rest of it.

ScrollView

XAML

```
<ScrollView Width="500" Height="400">
    <Rectangle Width="1000" Height="800">
        <Rectangle.Fill>
            <LinearGradientBrush StartPoint="0,0" EndPoint="1,1">
                <GradientStop Color="Yellow" Offset="0.0" />
                <GradientStop Color="Red" Offset="0.25" />
                <GradientStop Color="Blue" Offset="0.75" />
                <GradientStop Color="LimeGreen" Offset="1.0" />
            </LinearGradientBrush>
        </Rectangle.Fill>
    </Rectangle>
</ScrollView>
```

Layout

In the previous example, the size of the rectangle is explicitly set to be larger than the scroll viewer. In cases were the scroll viewer content is allowed to grow naturally, like in a list or text block, you can configure the scroll viewer to let its content (the *extent*) expand vertically, horizontally, both, or neither.

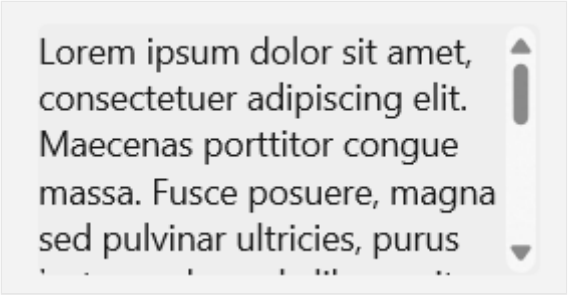
For example, this text block will grow horizontally until its parent container constrains it, then wrap the text and grow vertically.

XAML

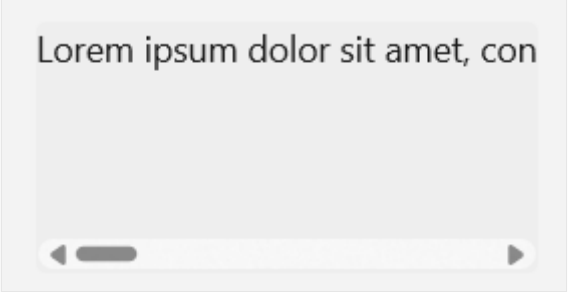
```
<TextBlock Text="{x:Bind someText}" TextWrapping="WrapWholeWords"/>
```

When the text block is wrapped in a scroll viewer, the scroll viewer constrains its horizontal and vertical growth.

Vertical means that the content is constrained horizontally, but can grow vertically beyond the viewport bounds, and the user can scroll the content up and down.



Horizontal means that the content is constrained vertically, but can grow horizontally beyond the viewport bounds, and the user can scroll the content left and right.



Scrollbar visibility

The ScrollViewer and ScrollView controls use slightly different means to configure the horizontal and vertical scrolling of content.

- In the ScrollViewer control, the VerticalScrollBarVisibility and HorizontalScrollBarVisibility properties control both the visibility of the scrollbars and whether scrolling in a particular direction is allowed. When a property is set to `Disabled`, content can't be scrolled in that direction by user interaction.
  - The defaults are: `VerticalScrollBarVisibility="Auto"`, `HorizontalScrollBarVisibility="Disabled"`
- In the ScrollView control, the VerticalScrollBarVisibility and HorizontalScrollBarVisibility properties control only the visibility of the scrollbars.

- The defaults are: `VerticalScrollBarVisibility="Auto"`, `HorizontalScrollBarVisibility="Auto"`

This table describes the visibility options for these properties.

Expand table

Value	Description
Auto	A scrollbar appears only when the viewport cannot display all of the content.
Disabled (ScrollViewer only)	A scrollbar does not appear even when the viewport cannot display all of the content. Scrolling by user interaction is disabled. (Programmatic scrolling is still possible.)
Hidden	A scrollbar does not appear even when the viewport cannot display all of the content. Scrolling is still enabled, and can occur through touch, keyboard, or mouse wheel interaction.
Visible	A scrollbar always appears. (In current UX designs, the scrollbar appears only when the mouse cursor is over it unless the viewport cannot display all of the content.)

(ScrollViewer uses the ScrollBarVisibility enum; ScrollView uses the ScrollingScrollBarVisibility enum.)

Orientation

The ScrollView control has a ContentOrientation property that let's you control the layout of content. This property determines how content can grow when it's not explicitly constrained. If `Height` and `Width` are explicitly set on the content, `ContentOrientation` has no effect.

This table shows the `ContentOrientation` options for ScrollView and the equivalent settings for ScrollViewer.

Expand table

Orientation	ScrollView	ScrollViewer
Vertical	`ContentOrientation="Vertical"`	`VerticalScrollBarVisibility="[Auto][Visible][Hidden]"` `HorizontalScrollBarVisibility="Disabled"`
Horizontal	`ContentOrientation="Horizontal"`	`VerticalScrollBarVisibility="Disabled"` `HorizontalScrollBarVisibility="[Auto]`

Orientation	ScrollView	ScrollViewer
		`[Visible][Hidden]"`
Both	`ContentOrientation="Both"`	`VerticalScrollBarVisibility="[Auto][Visible][Hidden]"` `HorizontalScrollBarVisibility="[Auto][Visible][Hidden]"`
None	`ContentOrientation="None"`	`VerticalScrollBarVisibility="Disabled"` `HorizontalScrollBarVisibility="Disabled"`

Vertical layout

By default, a scroll viewer's content layout (orientation) is vertical.

In this example, an ItemsRepeater is used as the ScrollView's `Content`. The UniformGridLayout for the ItemsRepeater positions the items horizontally in a row until it runs out of space (500px in this example), then positions the next item on the next row. The ItemsRepeater may be taller than the 400px that the user can see, but the user can then scroll the content vertically.

ScrollView

The default `ContentOrientation` value is `Vertical`, so no changes are needed on the ScrollView.

XAML

```
<ScrollView Width="500" Height="400">
    <ItemsRepeater ItemsSource="{x:Bind Albums}"
                   ItemTemplate="{StaticResource MyTemplate}">
        <ItemsRepeater.Layout>
            <UniformGridLayout RowSpacing="8" ColumnSpacing="8"/>
        </ItemsRepeater.Layout>
    </ItemsRepeater>
</ScrollView>
```

Horizontal layout

In this example the content is a `StackPanel` that is laying out its items horizontally. The scroll viewer configuration is changed to support horizontal scrolling and disable vertical scrolling.

ScrollView

The `ScrollView`'s `ContentOrientation` property is set to `Horizontal` to allow the content to grow horizontally as much as needed.

XAML

```
<ScrollView Width="500" Height="400" ContentOrientation="Horizontal">
    <StackPanel Orientation="Horizontal">
        <Button Width="200" Content="Button 1"/>
        <Button Width="200" Content="Button 2"/>
        <Button Width="200" Content="Button 3"/>
        <Button Width="200" Content="Button 4"/>
        <Button Width="200" Content="Button 5"/>
    </StackPanel>
</ScrollView>
```

Programmatic scrolling

The scroll viewer's *offset* properties are read-only, but methods are provided to let you scroll programmatically.

ScrollView

For the ScrollView control, call the ScrollTo method and pass the horizontal and vertical offsets to scroll to. In this case, the scrolling is only vertical, so the current HorizontalOffset value is used. To scroll to the top, a VerticalOffset of 0 is used. To scroll to the bottom, the `VerticalOffset` is the same as the ScrollableHeight.

XAML

```
<Button Content="Scroll to top" Click="ScrollTopButton_Click"/>
<Button Content="Scroll to bottom" Click="ScrollBottomButton_Click"/>
<ScrollView x:Name="scrollView" Width="500" Height="400">
    <StackPanel>
        <Button Width="200" Content="Button 1"/>
        <Button Width="200" Content="Button 2"/>
        <Button Width="200" Content="Button 3"/>
        <Button Width="200" Content="Button 4"/>
        <Button Width="200" Content="Button 5"/>
    </StackPanel>
</ScrollView>
```

C#

```
private void ScrollTopButton_Click(object sender, RoutedEventArgs e)
{
    scrollView.ScrollTo(
        horizontalOffset: scrollView.HorizontalOffset,
        verticalOffset: 0);
}

private void ScrollBottomButton_Click(object sender, RoutedEventArgs e)
{
    scrollView.ScrollTo(
        horizontalOffset: scrollView.HorizontalOffset,
        verticalOffset: scrollView.ScrollableHeight);
}
```

ScrollView also provides a ScrollBy method that lets you scroll vertically or horizontally by a specified delta from the current offset.

Zoom

You can use a scroll viewer to let a user optically zoom in and out of content. Optical zoom interactions are performed through the pinch and stretch gestures (moving fingers farther apart zooms in and moving them closer together zooms out), or by pressing the Ctrl key while scrolling the mouse scroll wheel. For more info about zooming, see Optical zoom and resizing.

To enable zoom by user interaction, set the `ZoomMode` property to `Enabled` (it's `Disabled` by default). Changes to the `ZoomMode` property take effect immediately and may affect an on-going user interaction.

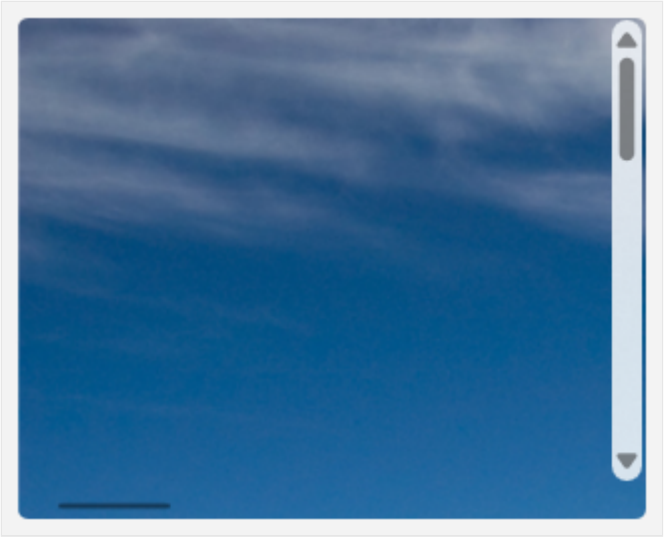
This example shows an Image wrapped in a scroll viewer that's configured to allow zooming.

ScrollView

XAML

```
<ScrollView Width="500" Height="400"
            ContentOrientation="Both"
            ZoomMode="Enabled">
    <Image Source="Assets/rainier.jpg"/>
</ScrollView>
```

In this case, the Image is unconstrained by the scroll viewer, so it's initially shown at its native size. If the image source is larger than the viewport, the user will need to zoom out to see the entire image, which may not be the intended behavior.



The next example shows how to configure the scroll viewer to constrain the image to the viewport so that it's initially loaded zoomed out, and the user can zoom in and scroll if they want to.

ScrollView

To constrain the image to the ScrollView's viewport, set the ContentOrientation property to `None`. Because the scrollbar visibility is not tied to this constraint, scrollbars appear automatically when the user zooms in.

XAML

```
<ScrollView Width="500" Height="400"
            ContentOrientation="None"
            ZoomMode="Enabled">
```

```
    <Image Source="Assets/rainier.jpg"/>
</ScrollView>
```

Zoom factor

Use the `MinZoomFactor` and `MaxZoomFactor` properties to control the amount the user can zoom the content. These properties are effective for both user interactions and programmatic zooming.

- The defaults are: `MinZoomFactor="0.1"`, `MaxZoomFactor="10.0"`

ScrollView

XAML

```
<ScrollView Width="500" Height="400"
            ContentOrientation="Both"
            ZoomMode="Enabled"
            MinZoomFactor="1.0" MaxZoomFactor="8.0">
    <Image Source="Assets/rainier.png"/>
</ScrollView>
```

Programmatic zoom

The `ZoomFactor` property is read-only, but methods are provided to let you zoom programmatically. A typical use for this is to connect the scroll viewer to a Slider that controls the zoom amount, or a button to reset the zoom level. (See ScrollViewer in the WinUI 3 Gallery app to see an example of a zoom slider.)

ScrollView

For the ScrollView control, call the ZoomTo method and pass the new zoom factor as the first parameter.

XAML

```
<Slider Header="Zoom" IsEnabled="True"
        Maximum="{x:Bind scrollControl.MaxZoomFactor, Mode=OneWay}"
        Minimum="{x:Bind scrollControl.MinZoomFactor, Mode=OneWay}"
        StepFrequency="0.1"
        ValueChanged="ZoomSlider_ValueChanged" />
<ScrollView Width="500" Height="400"
            ContentOrientation="None"
```

```
            ZoomMode="Enabled">
    <Image Source="Assets/rainier.png"/>
</ScrollView>
```

C#

```
private void ZoomSlider_ValueChanged(object sender,
RangeBaseValueChangedEventArgs e)
{
    if (scrollControl != null)
    {
        scrollControl.ZoomTo(
            zoomFactor: (float)e.NewValue,
            centerPoint: null)
    }
}
```

ScrollView also provides a ZoomBy method that lets you zoom in and out by a specified delta from the current zoom level.

UWP and WinUI 2

> **Note**
>
> The `ScrollView` control is available only in WinUI 3. For UWP and WinUI 2, use the `ScrollViewer` control.

> **Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

APIs for this control exist in the Windows.UI.Xaml.Controls namespace.

- ✓ **UWP APIs:** ScrollViewer class, ScrollBar class
- ✓ Open the WinUI 2 Gallery app and see the ScrollViewer in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and

functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles and templates for all controls. WinUI 2.2 or later includes a new template for this control that uses rounded corners. For more info, see Corner radius.

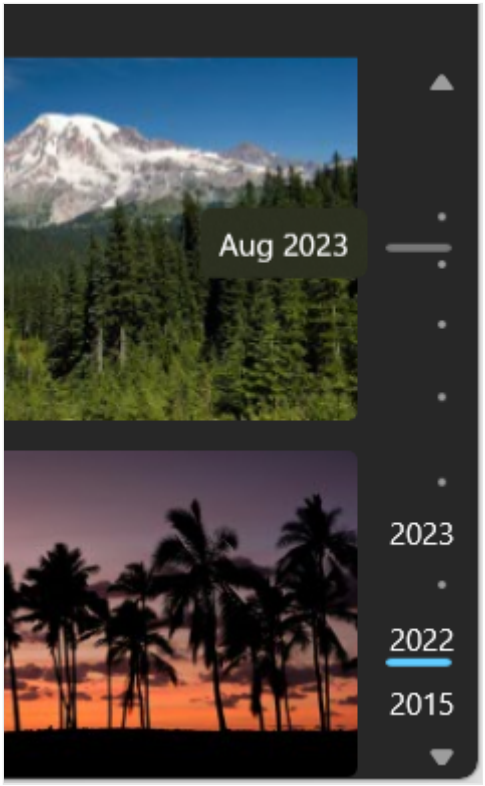
Annotated scrollbar control

Article • 10/01/2023

An annotated scrollbar helps users easily navigate through a large collection of items. It replaces the default scrollbar and can be used in conjunction with any scrollable container. This vertical scrollbar allows users to scroll up and down through the items in a collection. Users can see category labels along the scrollbar area to provide a visual reference of where they are within their collection. A panning indicator (accent-colored line) indicates the user's current position in the collection. A tooltip is revealed when a user hovers on the scrollbar area. This tooltip contains a label to give more information to the user about their current position in the collection. Scroll arrows are located at the top and bottom of the scrollbar area. They can be used to move the current position by a small increment



The annotated scrollbar can be used in conjunction with an ItemsView control to recreate a photo gallery experience. The category labels can be set to different years to help users navigate to a specific location within their photo collection.

Interactions

On hover, a tooltip is revealed to show a preview of that location. Users can then click to navigate to that specific location. Users can also click and drag anywhere on the scrollbar area to navigate to a new position within their collection. As they drag, the

panning indicator stays attached to the mouse cursor and the content scrolls to reflect the new position. Users can also scroll through their collection by using the mouse wheel. Scrolling up or down on the mouse wheel moves their position in the collection and the corresponding panning indicator up or down by a fixed amount.

> **Note**
>
> Unlike in a ScrollBar control, you can't click-and-drag the thumb. The thumb is a non-interactive element that is only for visualizing the current viewport position. The thumb has a fixed height which is not representative of the viewport height.

Label behavior

- For experiences optimized for touch input, users can tap and hold on the scrollbar area to see the tooltip. The tooltip will be slightly more elevated to make it easier to read for touch users. Tapping and dragging anywhere on the scrollbar area will work similarly to a click and drag with mouse.
- The tooltip label is never truncated as its purpose is to display text that's explanatory. Instead, the text is wrapped if it goes over the tooltip's max width of 360px.
- Category labels are clipped if the text is longer than the width of the scrollbar's area.
- When there is a collision between two category labels (for example, when the window size decreases and two labels overlap each other), the top label is removed. As an exception to this rule, the first label of the collection is always kept as it helps to indicate the range of the collection to users. Category labels should always have a minimum of 4px (2px above, 2px below) in between, otherwise a label-collision is triggered.

Is this the right control?

We recommend using an annotated scrollbar, rather than a default scrollbar, when dealing with a large collection of items or when a large amount of scrolling is expected. The annotated scrollbar will provide an easy way for users to locate themselves in their collection and to traverse it.

For collections that only have a few items or that only require a small amount of scrolling, we recommend using a default scrollbar.

Recommendations

- Only add a category label if it provides helpful information to users
- Keep the strings used for the category labels and the tooltip as concise as possible
- The annotated scrollbar is best used when there is sufficient vertical space. Using the annotated scrollbar in a confined vertical space will reduce the number of visible labels
- Do not use the annotated scrollbar as the only way for users to locate themselves within a collection. We recommend using sticky headers or category labels throughout your collection to complement the annotated scrollbar.

Create an annotated scrollbar

✓ **Important APIs:** AnnotatedScrollBar class, ScrollView class, IScrollController interface

Open the WinUI 3 Gallery app and see the AnnotatedScrollBar in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

To use an AnnotatedScrollBar, you need to complete several steps:

- Connect the AnnotatedScrollBar to a scrolling container.
- Add labels to the scrollbar.
- Add detail labels (tooltips).

Connect the AnnotatedScrollBar to a scrolling container

To use an AnnotatedScrollBar, you connect it to a scrollable container via the IScrollController interface. The AnnotatedScrollBar provides an IScrollController implementation through its ScrollController property, while the ScrollView consumes it through its ScrollPresenter property (specifically, ScrollPresenter.VerticalScrollController).

> ⓘ **Note**
>
> The ScrollView control has built in support for consuming the IScrollController interface. For other scrolling containers, like ScrollViewer, you must write an adapter for IScrollController. See an example later in this article.

Here, the VerticalScrollController property of an ItemsView is bound to the ScrollController of an AnnotatedScrollBar. (The ItemsView.VerticalScrollPresenter property is passed through to the ScrollPresenter.VerticalScrollController value of the ItemsView's inner ScrollView.)

XAML

```
<Grid ColumnDefinitions="*,Auto">
    <ItemsView VerticalScrollController="{x:Bind
annotatedScrollBar.ScrollController}"/>
    <AnnotatedScrollBar x:Name="annotatedScrollBar" Grid.Column="1"/>
</Grid>
```

You can also connect them in code, as shown here. In this example, a ScrollView is used to wrap an ItemsRepeater and provide scrolling functionality for it. The AnnotatedScrollBar replaces the ScrollView's default scrollbar.

XAML

```
<Grid ColumnDefinitions="*, Auto">
    <ScrollView x:Name="scrollView"
                Background="LightGray"
                MaxWidth="800" MaxHeight="500"
                VerticalScrollBarVisibility="Hidden">
        <ItemsRepeater x:Name="itemsRepeater"
                ItemsSource="{x:Bind ColorCollection}"
                Margin="2"
                SizeChanged="ItemsRepeater_SizeChanged">
            <ItemsRepeater.Layout>
                <UniformGridLayout/>
            </ItemsRepeater.Layout>
            <ItemsRepeater.ItemTemplate>
                <DataTemplate x:DataType="media:SolidColorBrush">
                    <Grid Background="{x:Bind}" Width="112" Height="82"
                          CornerRadius="4" Margin="4"/>
                </DataTemplate>
            </ItemsRepeater.ItemTemplate>
        </ItemsRepeater>
    </ScrollView>

    <AnnotatedScrollBar x:Name="annotatedScrollBar" Grid.Column="1"
        Margin="4,0,48,0" MaxHeight="500" HorizontalAlignment="Right"
        DetailLabelRequested="AnnotatedScrollBar_DetailLabelRequested"/>
</Grid>
```

C#

```
private void AnnotatedScrollBarPage_Loaded(object sender,
Microsoft.UI.Xaml.RoutedEventArgs e)
```

```
{
    scrollView.ScrollPresenter.VerticalScrollController =
annotatedScrollBar.ScrollController;
}
```

Labels

The AnnotatedScrollBar can display two kinds of labels, both of which are optional.

Category labels

You add labels by populating the Labels collection. Each Label is represented by the AnnotatedScrollBarLabel class and requires two pieces of information:

- Content: The content that is displayed on the scrollbar.
- ScrollOffset: The offset value at which the label content is displayed.

Labels (if specified) are always visible on the scrollbar, unless they collide with other labels or extend past the bounds of the rail. (See Label behavior for more info.)

The calculation of the label offset value depends on the details of your app and its data. For one example of how the offset can be calculated, see the WinUI Gallery example on GitHub.

Detail labels

A detail label is a tooltip element that is shown when the cursor is over the scrollbar. To create a detail label, you handle the DetailLabelRequested event. The event args provide the ScrollOffset where the tooltip label will be shown. Use this value to determine the correct label to show for that position, and set the label as the Content property of the event args.

Scrolling

The user can scroll the AnnotatedScrollBar by clicking the arrow buttons at the top and bottom of the scrollbar. You can set the SmallChange property to specify the amount by which the arrow buttons scroll the content.

You can handle the Scrolling event to determine how the scrolling is being performed, take an action when scrolling occurs, or to Cancel the scroll action.

Semantic zoom

Article • 02/26/2025

Semantic zoom lets the user switch between two different views of the same content so that they can quickly navigate through a large set of grouped data.

- The zoomed-in view is the main view of the content. This is the main view where you show individual data items.
- The zoomed-out view is a higher-level view of the same content. You typically show the group headers for a grouped data set in this view.

For example, when viewing an address book, the user could zoom out to quickly jump to the letter "W", and zoom in on that letter to see the names associated with it.

Features:

- The size of the zoomed-out view is constrained by the bounds of the semantic zoom control.
- Tapping on a group header toggles views. Pinching as a way to toggle between views can be enabled.
- Active headers switch between views.

Is this the right control?

Use a **SemanticZoom** control when you need to show a grouped data set that's large enough that it can't all be shown on one or two pages.

Don't confuse semantic zooming with optical zooming. While they share both the same interaction and basic behavior (displaying more or less detail based on a zoom factor), optical zoom refers to the adjustment of magnification for a content area or object such as a photograph. For info about a control that performs optical zooming, see the ScrollViewer control.

Recommendations

- When using semantic zoom in your app, be sure that the item layout and panning direction don't change based on the zoom level. Layouts and panning interactions should be consistent and predictable across zoom levels.
- Semantic zoom enables the user to jump quickly to content, so limit the number of pages/screens to three in the zoomed-out mode. Too much panning diminishes the practicality of semantic zoom.

- Avoid using semantic zoom to change the scope of the content. For example, a photo album shouldn't switch to a folder view in File Explorer.
- Use a structure and semantics that are essential to the view.
- Use group names for items in a grouped collection.
- Use sort ordering for a collection that is ungrouped but sorted, such as chronological for dates or alphabetical for a list of names.

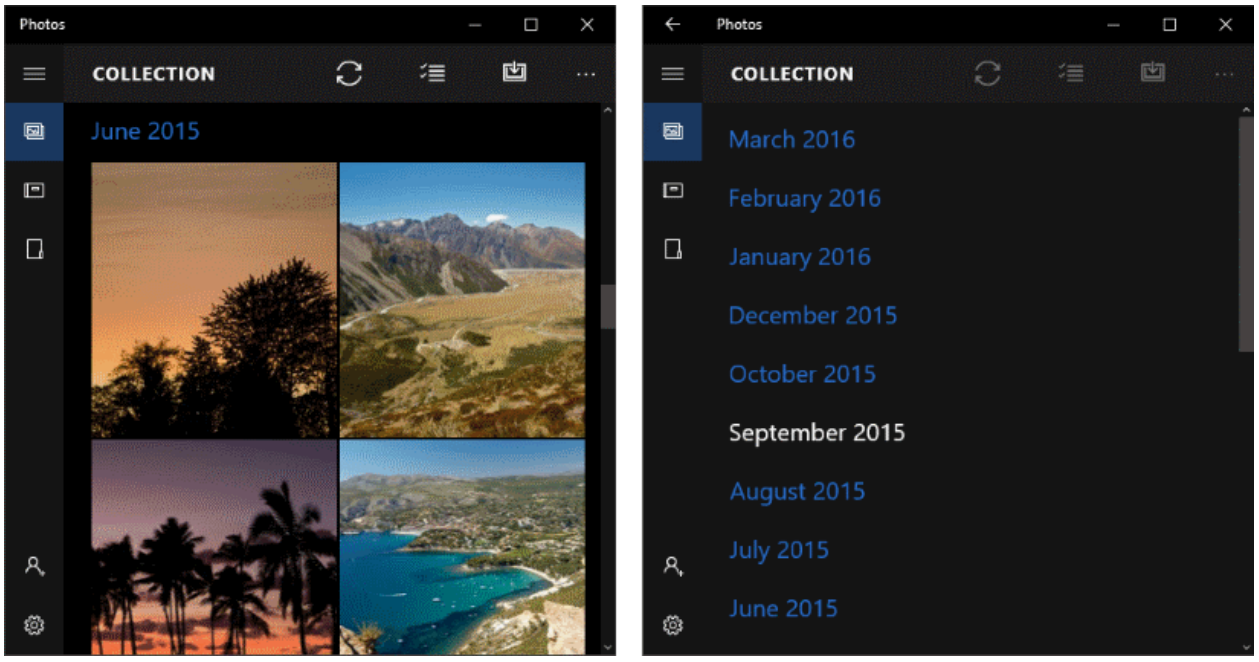
Examples

WinUI Gallery

The SemanticZoom section within the Controls Gallery demonstrates a navigation experience that allows users to quickly zoom in and out of grouped sections of control types.

Photos app

Here's a semantic zoom used in the Photos app. Photos are grouped by month. Selecting a month header in the default grid view zooms out to the month list view for quicker navigation.



Create a semantic zoom

✓ **Important APIs:** SemanticZoom class, ListView class, GridView class

Open the WinUI 3 Gallery app and see SemanticZoom in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

The **SemanticZoom** control doesn't have any visual representation of its own. It's a host control that manages the transition between 2 other controls that provide the views of your content, typically **ListView** or **GridView** controls. You set the view controls to the ZoomedInView and ZoomedOutView properties of the SemanticZoom.

The 3 elements you need for a semantic zoom are:

- A grouped data source. (Groups are defined by the GroupStyle definition in the zoomed-in view.)
- A zoomed-in view that shows the item-level data.
- A zoomed-out view that shows the group-level data.

Before you use a semantic zoom, you should understand how to use a list view with grouped data. For more info, see List view and grid view.

> ⓘ **Note**

To define the zoomed-in view and the zoomed-out view of the SemanticZoom control, you can use any two controls that implement the ISemanticZoomInformation interface. The XAML framework provides 3 controls that implement this interface: ListView, GridView, and Hub.

This XAML shows the structure of the SemanticZoom control. You assign other controls to the ZoomedInView and ZoomedOutView properties.

XAML

```
<SemanticZoom>
   <SemanticZoom.ZoomedInView>
       <!-- Put the GridView for the zoomed in view here. -->
   </SemanticZoom.ZoomedInView>

   <SemanticZoom.ZoomedOutView>
       <!-- Put the ListView for the zoomed out view here. -->
   </SemanticZoom.ZoomedOutView>
</SemanticZoom>
```

The examples here are taken from the SemanticZoom page of the WinUI Gallery sample. You can download the sample to see the complete code including the data source. This semantic zoom uses a GridView to supply the zoomed-in view and a ListView for the zoomed-out view.

Define the zoomed-in view

Here's the GridView control for the zoomed-in view. The zoomed-in view should display the individual data items in groups. This example shows how to display the items in a grid with an image and text.

XAML

```
<SemanticZoom.ZoomedInView>
    <GridView ItemsSource="{x:Bind cvsGroups.View}"
              ScrollViewer.IsHorizontalScrollChainingEnabled="False"
              SelectionMode="None"
              ItemTemplate="{StaticResource ZoomedInTemplate}">
        <GridView.GroupStyle>
            <GroupStyle HeaderTemplate="{StaticResource
ZoomedInGroupHeaderTemplate}"/>
        </GridView.GroupStyle>
    </GridView>
</SemanticZoom.ZoomedInView>
```

The look of the group headers is defined in the `ZoomedInGroupHeaderTemplate` resource. The look of the items is defined in the `ZoomedInTemplate` resource.

XAML

```
<DataTemplate x:Key="ZoomedInGroupHeaderTemplate"
x:DataType="data:ControlInfoDataGroup">
    <TextBlock Text="{x:Bind Title}"
               Foreground="{ThemeResource ApplicationForegroundThemeBrush}"
               Style="{StaticResource SubtitleTextBlockStyle}"/>
</DataTemplate>

<DataTemplate x:Key="ZoomedInTemplate"
x:DataType="data:ControlInfoDataItem">
    <StackPanel Orientation="Horizontal" MinWidth="200" Margin="12,6,0,6">
        <Image Source="{x:Bind ImagePath}" Height="80" Width="80"/>
        <StackPanel Margin="20,0,0,0">
            <TextBlock Text="{x:Bind Title}"
                       Style="{StaticResource BaseTextBlockStyle}"/>
            <TextBlock Text="{x:Bind Subtitle}"
                       TextWrapping="Wrap" HorizontalAlignment="Left"
                       Width="300" Style="{StaticResource
BodyTextBlockStyle}"/>
        </StackPanel>
    </StackPanel>
</DataTemplate>
```

Define the zoomed-out view

This XAML defines a ListView control for the zoomed-out view. This example shows how to display the group headers as text in a list.

XAML

```
<SemanticZoom.ZoomedOutView>
    <ListView ItemsSource="{x:Bind cvsGroups.View.CollectionGroups}"
              SelectionMode="None"
              ItemTemplate="{StaticResource ZoomedOutTemplate}" />
</SemanticZoom.ZoomedOutView>
```

The look is defined in the `ZoomedOutTemplate` resource.

XAML

```
<DataTemplate x:Key="ZoomedOutTemplate"
x:DataType="wuxdata:ICollectionViewGroup">
    <TextBlock Text="{x:Bind Group.(data:ControlInfoDataGroup.Title)}"
               Style="{StaticResource SubtitleTextBlockStyle}"
```

```
TextWrapping="Wrap"/>
</DataTemplate>
```

Synchronize the views

The zoomed-in view and zoomed-out view should be synchronized, so if a user selects a group in the zoomed-out view, the details of that same group are shown in the zoomed-in view. You can use a CollectionViewSource or add code to synchronize the views.

Any controls that you bind to the same CollectionViewSource always have the same current item. If both views use the same CollectionViewSource as their data source, the CollectionViewSource synchronizes the views automatically. For more info, see CollectionViewSource.

If you don't use a CollectionViewSource to synchronize the views, you should handle the ViewChangeStarted event and synchronize the items in the event handler, as shown here.

XAML

```
<SemanticZoom x:Name="semanticZoom"
ViewChangeStarted="SemanticZoom_ViewChangeStarted">
```

C#

```
private void SemanticZoom_ViewChangeStarted(object sender,
SemanticZoomViewChangedEventArgs e)
{
    if (e.IsSourceZoomedInView == false)
    {
        e.DestinationItem.Item = e.SourceItem.Item;
    }
}
```

UWP and WinUI 2

> **ⓘ Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that

use **WinUI 2**. See the UWP API reference for platform specific information and examples.

This section contains information you need to use the control in a UWP or WinUI 2 app.

APIs for this control exist in the Windows.UI.Xaml.Controls namespace.

- ✓ **UWP APIs:** SemanticZoom class, ListView class, GridView class
- ✓ Open the WinUI 2 Gallery app and see the SemanticZoom in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles and templates for all controls.

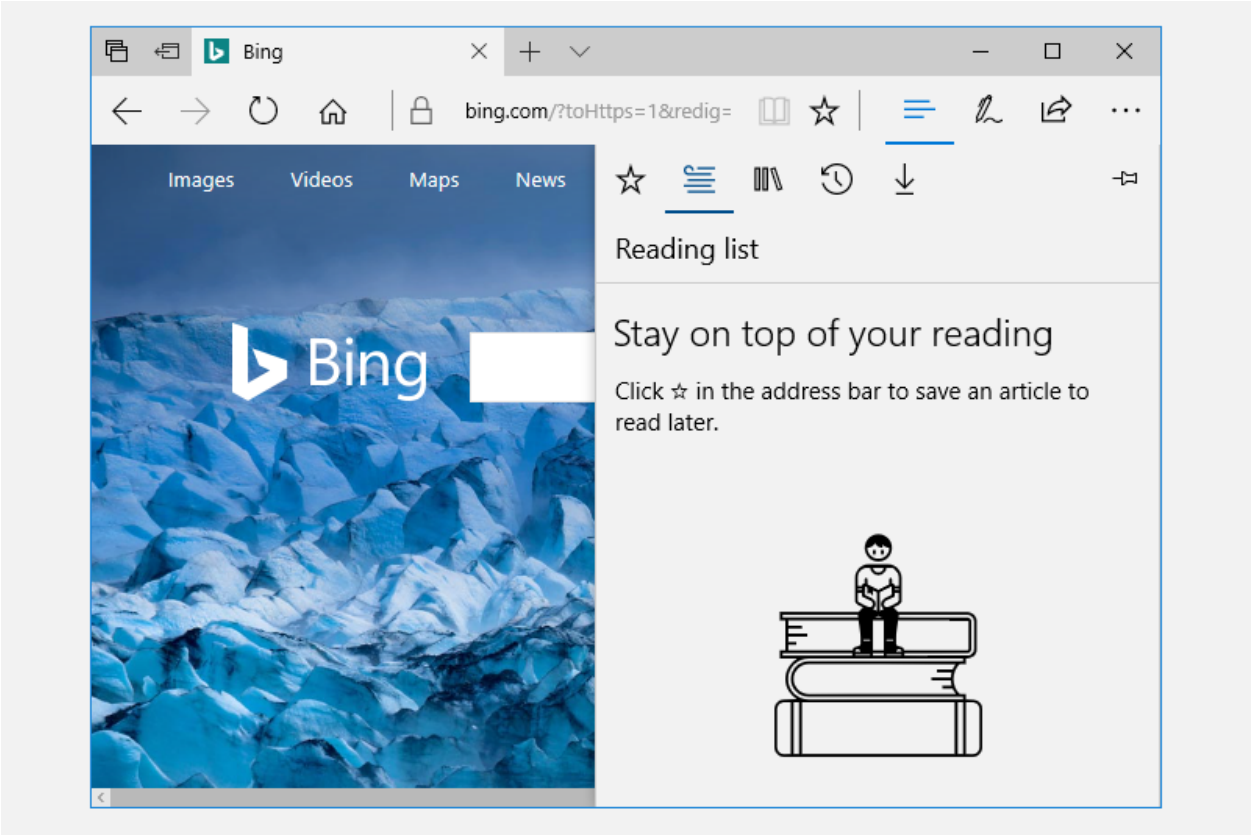
Split view control

Article • 06/09/2022

A split view control has an expandable/collapsible pane and a content area.

> **Important APIs**: SplitView class

Here is an example of the Microsoft Edge app using SplitView to show its Hub.



A split view's content area is always visible. The pane can expand and collapse or remain in an open state, and can present itself from either the left side or right side of an app window. The pane has four modes:

- **Overlay**

  The pane is hidden until opened. When open, the pane overlays the content area.

- **Inline**

  The pane is always visible and doesn't overlay the content area. The pane and content areas divide the available screen real estate.

- **CompactOverlay**

A narrow portion of the pane is always visible in this mode, which is just wide enough to show icons. The default closed pane width is 48px, which can be modified with `CompactPaneLength`. If the pane is opened, it will overlay the content area.

- **CompactInline**

  A narrow portion of the pane is always visible in this mode, which is just wide enough to show icons. The default closed pane width is 48px, which can be modified with `CompactPaneLength`. If the pane is opened, it will reduce the space available for content, pushing the content out of its way.

Is this the right control?

The split view control can be used to create any "drawer" experience where users can open and close the supplemental pane. For example, you can use SplitView to build the list/details pattern.

If you'd like to build a navigation menu with an expand/collapse button and a list of navigation items, then use the NavigationView control.

Examples

WinUI 2 Gallery

If you have the **WinUI 2 Gallery** app installed, click here to open the app and see the SplitView in action.

- Get the WinUI 2 Gallery app (Microsoft Store)
- Get the source code (GitHub)

Create a split view

Here's a SplitView control with an open Pane appearing inline next to the Content.

XAML

```
<SplitView IsPaneOpen="True"
           DisplayMode="Inline"
           OpenPaneLength="296">
    <SplitView.Pane>
        <TextBlock Text="Pane"
                   FontSize="24"
```

```
                    VerticalAlignment="Center"
                    HorizontalAlignment="Center"/>
    </SplitView.Pane>

    <Grid>
        <TextBlock Text="Content"
                   FontSize="24"
                   VerticalAlignment="Center"
                   HorizontalAlignment="Center"/>
    </Grid>
</SplitView>
```

Two-pane view

Article • 06/09/2022

TwoPaneView is a layout control that helps you manage the display of apps that have 2 distinct areas of content, like a list/detail view.

> **Important**
>
> This article describes functionality and guidance that is in public preview and may be substantially modified before it's generally available. Microsoft makes no warranties, express or implied, with respect to the information provided here.

While it works on all Windows devices, the TwoPaneView control is designed to help you take full advantage of dual-screen devices automatically, with no special coding needed. On a dual-screen device, the two-pane view ensures that the user interface (UI) is split cleanly when it spans the gap between screens, so that your content is presented on either side of the gap.

Get WinUI

The **TwoPaneView** control is included as part of WinUI, a NuGet package that contains new controls and UI features for Windows apps. For more info, including installation instructions, see WinUI.

> **WinUI APIs:** TwoPaneView class

> **Tip**
>
> Throughout this document, we use the **muxc** alias in XAML to represent WinUI APIs that we have included in our project. We have added this to our **Page** element: `xmlns:muxc="using:Microsoft.UI.Xaml.Controls"`
>
> In the code-behind, we also use the **muxc** alias in C# to represent WinUI APIs that we have included in our project. We have added this **using** statement at the top of the file: `using muxc = Microsoft.UI.Xaml.Controls;`

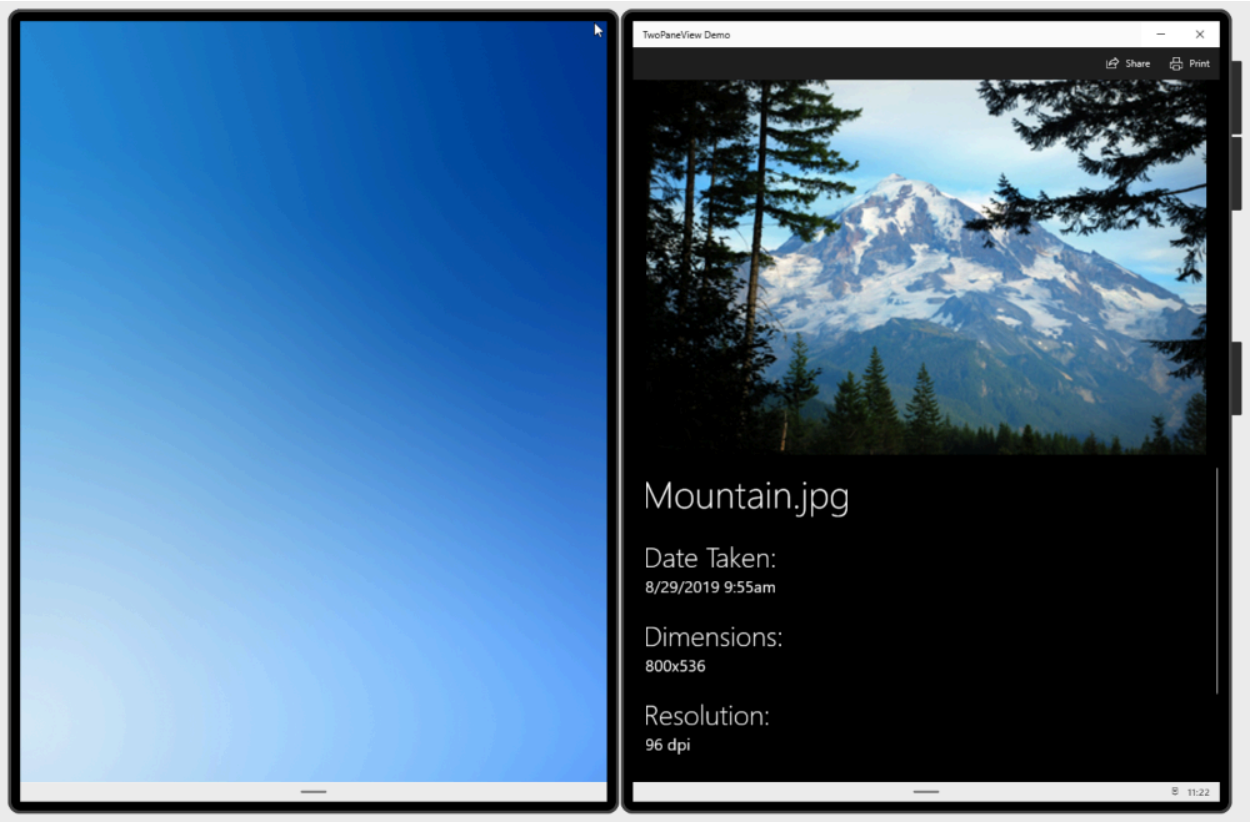
Is this the right control?

Use the two-pane view when you have 2 distinct areas of content and:

- The content should automatically rearrange and resize to best fit the window.
- The secondary area of content should show/hide based on available space.
- The content should split cleanly between the 2 screens of a dual-screen device.

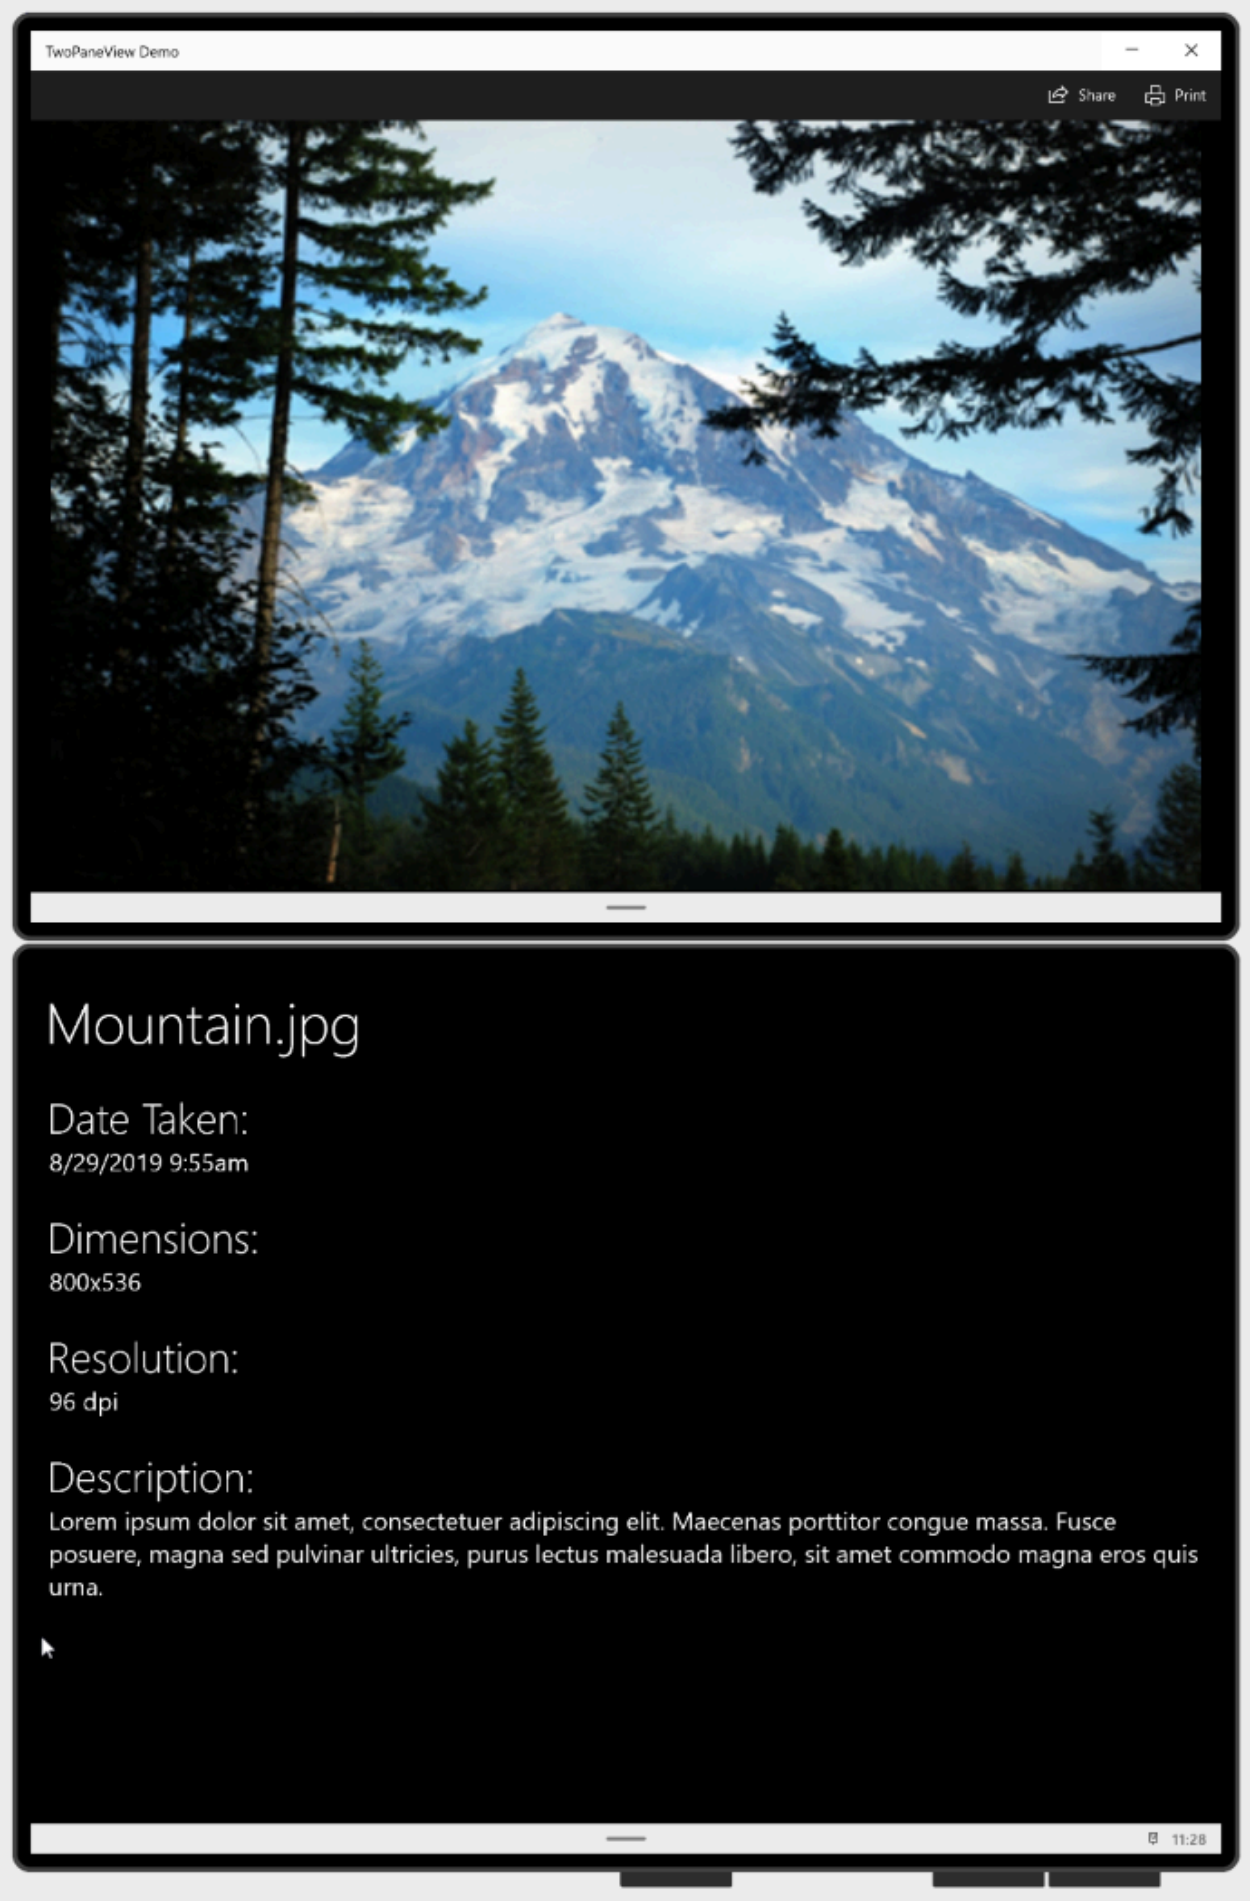
Examples

These images show an app running on a single-screen and spanned across dual-screens. The two-pane view adapts the app UI to the various screen configurations.



> *App on a single-screen.*

> *App spanning a dual-screen device in wide mode.*



> *App spanning a dual-screen device in tall mode.*

How it works

The two-pane view has two panes where you place your content. It adjusts the size and arrangement of the panes depending on the space available to the window. The possible pane layouts are defined by the TwoPaneViewMode enumeration:

Expand table

Enum value	Description
`SinglePane`	Only one pane is shown, as specified by the PanePriority property.
`Wide`	Panes are shown side-by-side, or a single pane is shown, as specified by the WideModeConfiguration property.
`Tall`	Panes are shown top-bottom, or a single pane is shown, as specified by the TallModeConfiguration property.

You configure the two-pane view by setting the PanePriority to specify which pane is shown when there is space for only one pane. Then, you specify whether `Pane1` is shown on the top or bottom for tall windows, or on the left or right for wide windows.

The two-pane view handles the size and arrangement of the panes, but you still need to make the content inside the pane adapt to the changes in size and orientation. See Responsive layouts with XAML and Layout panels for more info about creating an adaptive UI.

The TwoPaneView manages the display of the panes based on the spanning state of the app.

- On a single-screen

  When your app is on only a single screen, the `TwoPaneView` adjusts the size and position of its panes based on property settings you specify. We explain these properties in more detail in the next section. The only difference between devices is that some devices, like desktop PCs, allow re-sizable windows, while other devices don't.

- Spanned across dual-screens

  The `TwoPaneView` is designed to make it easy to optimize your UI for spanning on dual-screen devices. The window sizes itself to use all the available space on the screens. When your app spans both screens of a dual-screen device, each screen displays the content of one of the panes and properly spans content across the gap. Spanning-awareness is built-in when you use two-pane view. You only need

to set the tall/wide configuration to specify which pane is shown on which screen. The two-pane view takes care of the rest.

How to use the two-pane view control

The TwoPaneView doesn't have to be the root element of your page layout. In fact, you'll often use it inside a NavigationView control that provides the overall navigation for your app. The `TwoPaneView` adapts appropriately regardless of where it is in the XAML tree; however, we do recommend that you not nest a `TwoPaneView` inside another `TwoPaneView`. (If you do, only the outer `TwoPaneView` is spanning-aware.)

Add content to the panes

Each pane of a two-pane view can hold a single XAML `UIElement`. To add content, you typically place a XAML layout panel in each pane, and then add other controls and content to the panel. The panes can change size and switch between wide and tall modes, so you need to make sure the content in each pane can adapt to these changes. See Responsive layouts with XAML and Layout panels for more info about creating an adaptive UI.

This example creates the simple picture/info app UI shown previously in the *Examples* section. When the app is spanned across dual-screens, the picture and the info are shown on separate screens. On a single screen, the content can be shown in two panes, or combined into a single pane, depending on how much space is available. (When there's only space for one pane, you move the content of Pane2 into Pane1, and let the user scroll to see any hidden content. You'll see the code for this later in the *Responding to mode changes* section.)

XAML

```
<Grid>
    <Grid.RowDefinitions>
        <RowDefinition Height="Auto" MinHeight="40"/>
        <RowDefinition Height="*"/>
    </Grid.RowDefinitions>

    <CommandBar DefaultLabelPosition="Right">
        <AppBarButton x:Name="Share" Icon="Share" Label="Share"
Click="Share_Click"/>
        <AppBarButton x:Name="Print" Icon="Print" Label="Print"
Click="Print_Click"/>
    </CommandBar>

    <muxc:TwoPaneView
        x:Name="MyTwoPaneView"
        Grid.Row="1"
        MinWideModeWidth="959"
        MinTallModeHeight="863"
        ModeChanged="TwoPaneView_ModeChanged">

        <muxc:TwoPaneView.Pane1>
            <Grid x:Name="Pane1Root">
                <ScrollViewer>
                    <StackPanel x:Name="Pane1StackPanel">
                        <Image Source="Assets\LandscapeImage8.jpg"
                               VerticalAlignment="Top"
HorizontalAlignment="Center"
                               Margin="16,0"/>
                    </StackPanel>
                </ScrollViewer>
            </Grid>
        </muxc:TwoPaneView.Pane1>

        <muxc:TwoPaneView.Pane2>
            <Grid x:Name="Pane2Root">
                <ScrollViewer x:Name="DetailsContent">
                    <StackPanel Padding="16">
                        <TextBlock Text="Mountain.jpg" MaxLines="1"
                                   Style="{ThemeResource
HeaderTextBlockStyle}"/>
                        <TextBlock Text="Date Taken:"
                                   Style="{ThemeResource
SubheaderTextBlockStyle}"
                                   Margin="0,24,0,0"/>
                        <TextBlock Text="8/29/2019 9:55am"
                                   Style="{ThemeResource
SubtitleTextBlockStyle}"/>
                        <TextBlock Text="Dimensions:"
                                   Style="{ThemeResource
SubheaderTextBlockStyle}"
                                   Margin="0,24,0,0"/>
                        <TextBlock Text="800x536"
                                   Style="{ThemeResource
SubtitleTextBlockStyle}"/>
```

```
                        <TextBlock Text="Resolution:"
                                   Style="{ThemeResource
SubheaderTextBlockStyle}"
                                   Margin="0,24,0,0"/>
                        <TextBlock Text="96 dpi"
                                   Style="{ThemeResource
SubtitleTextBlockStyle}"/>
                        <TextBlock Text="Description:"
                                   Style="{ThemeResource
SubheaderTextBlockStyle}"
                                   Margin="0,24,0,0"/>
                        <TextBlock Text="Lorem ipsum dolor sit amet,
consectetuer adipiscing elit. Maecenas porttitor congue massa. Fusce
posuere, magna sed pulvinar ultricies, purus lectus malesuada libero, sit
amet commodo magna eros quis urna."
                                   Style="{ThemeResource
SubtitleTextBlockStyle}"
                                   TextWrapping="Wrap"/>
                    </StackPanel>
                </ScrollViewer>
            </Grid>
        </muxc:TwoPaneView.Pane2>
    </muxc:TwoPaneView>

    <VisualStateManager.VisualStateGroups>
        <VisualStateGroup x:Name="TwoPaneViewStates">
            <VisualState x:Name="Normal"/>
            <VisualState x:Name="Wide">
                <VisualState.Setters>
                    <Setter Target="MyTwoPaneView.Pane1Length"
                            Value="2*"/>
                </VisualState.Setters>
            </VisualState>
        </VisualStateGroup>
    </VisualStateManager.VisualStateGroups>
</Grid>
```

Specify which pane to display

When the two-pane view can only display a single pane, it uses the PanePriority property to determine which pane to display. By default, PanePriority is set to **Pane1**. Here's how you can set this property in XAML or in code.

XAML

```
<muxc:TwoPaneView x:Name="MyTwoPaneView" PanePriority="Pane2">
```

C#

```
MyTwoPaneView.PanePriority =
Microsoft.UI.Xaml.Controls.TwoPaneViewPriority.Pane2;
```

Pane sizing

On a single screen, the size of the panes is determined by the Pane1Length and Pane2Length properties. These use GridLength values that support *auto* and *star*(*) sizing. See the *Layout properties* section of Responsive layouts with XAML for an explanation of auto and star sizing.

By default, `Pane1Length` is set to `Auto` and it sizes itself to fit its content. `Pane2Length` is set to `*` and it uses all the remaining space.

> *Panes with default sizing*

The default values are useful for a typical list/detail layout, where you have a list of items in `Pane1`, and a lot of details in `Pane2`. However, depending on your content, you might prefer to divide the space differently. Here, `Pane1Length` is set to `2*` so it gets twice as much space as `Pane2`.

XAML

```
<muxc:TwoPaneView x:Name="MyTwoPaneView" Pane1Length="2*">
```

Panes sized 2 and **

> **Note**
>
> As mentioned previously, when the app is spanned across dual-screens, these properties are ignored and each pane fills one of the screens.

If you set a pane to use auto sizing, you can control the size by setting the height and width of the Panel that holds the pane's content. In this case, you might need to handle the ModeChanged event and set the height and width constraints of the content as appropriate for the current mode.

Display in wide or tall mode

On a single screen, the two-pane view's display Mode is determined by the MinWideModeWidth and MinTallModeHeight properties. Both properties have a default value of 641px, the same as NavigationView.CompactThresholdWidth.

This table shows how the Height and Width of the TwoPaneView determine which display mode is used.

Expand table

TwoPaneView condition	Mode
`Width` > `MinWideModeWidth`	`Wide` mode is used
`Width` <= `MinWideModeWidth`, and `Height` > `MinTallModeHeight`	`Tall` mode is used
`Width` <= `MinWideModeWidth`, and `Height` <= `MinTallModeHeight`	`SinglePane` mode is used

> **Note**

As mentioned previously, when the app is spanned across dual-screens, these properties are ignored and display mode is determined based on the device *posture*.

Wide configuration options

The two-pane view enters `Wide` mode when there's a single display that's wider than the `MinWideModeWidth` property. `MinWideModeWidth` controls when the two-pane view enters wide mode. The default value is 641px, but you can change it to whatever you want. In general, you should set this property to whatever you want the minimum width of your pane to be.

When the two-pane view is in wide mode, the WideModeConfiguration property determines what to show:

Expand table

Enum value	Description
`SinglePane`	A single pane (as determined by `PanePriority`). The pane takes up the full size of the `TwoPaneView` (ie, it's star sized in both directions).
`LeftRight`	`Pane1` on the left/`Pane2` on the right. Both panes are star sized vertically, `Pane1`'s width is autosized, and `Pane2`'s width is star sized.
`RightLeft`	`Pane1` on the right/`Pane2` on the left. Both panes are star sized vertically, `Pane2`'s width is autosized, and `Pane1`'s width is star sized.

The default setting is `LeftRight`.

Expand table

LeftRight	RightLeft

> **TIP:** When the device uses a right-to-left (RTL) language, the two-pane view automatically swaps the order: `RightLeft` renders as `LeftRight`, and `LeftRight` renders as `RightLeft`.

Tall configuration options

The two-pane view enters `Tall` mode when there's a single display that's narrower than `MinWideModeWidth`, and taller than `MinTallModeHeight`. The default value is 641px, but you can change it to whatever you want. In general, you should set this property to whatever you want the minimum height of your pane to be.

When the two-pane view is in tall mode, the TallModeConfiguration property determines what to show:

Expand table

Enum value	Description
`SinglePane`	A single pane (as determined by `PanePriority`). The pane takes up the full size of the `TwoPaneView` (ie, it's star sized in both directions).
`TopBottom`	`Pane1` on the top/`Pane2` on the bottom. Both panes are star sized horizontally, `Pane1`'s height is autosized, and `Pane2`'s height is star sized.
`BottomTop`	`Pane1` on the bottom/`Pane2` on the top. Both panes are star sized horizontally, `Pane2`'s height is autosized, and `Pane1`'s height is star sized.

The default is `TopBottom`.

Expand table

TopBottom	BottomTop

Special values for MinWideModeWidth and MinTallModeHeight

You can use the `MinWideModeWidth` property to prevent the two-pane view from entering Wide mode - just set `MinWideModeWidth` to Double.PositiveInfinity.

If you set `MinTallModeHeight` to Double.PositiveInfinity, it prevents the two-pane view from entering Tall mode.

If you set `MinTallModeHeight` to 0, it prevents the two-pane view from entering `SinglePane` mode.

Responding to mode changes

You can use the read-only Mode property to get the current display mode. Whenever the two-pane view changes which pane or panes it's displaying, the ModeChanged event occurs before it renders the updated content. You can handle the event to respond to changes in the display mode.

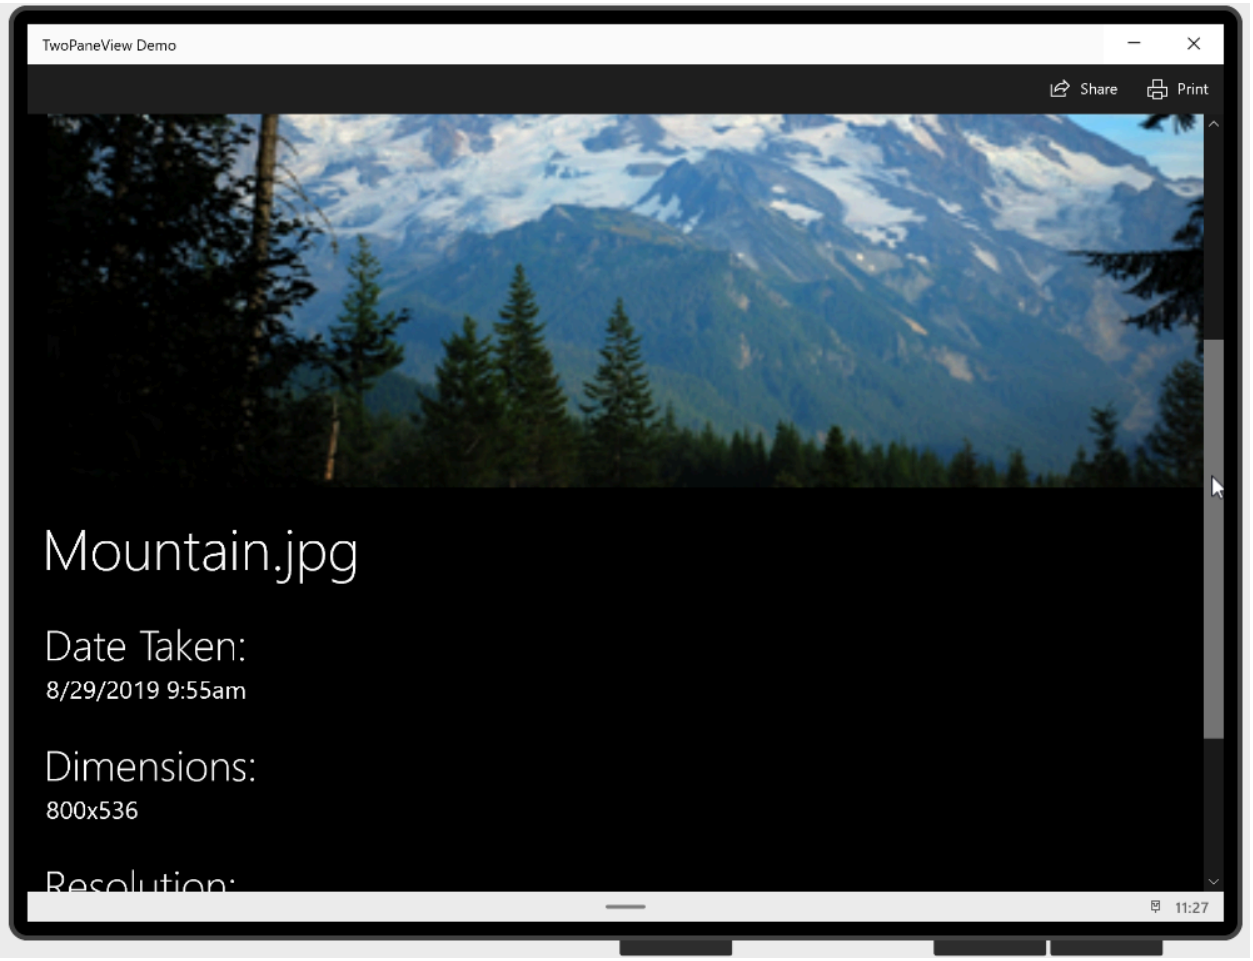
> **Tip**

The `ModeChanged` event does not occur when the page is initially loaded, so your default XAML should represent the UI as it should appear when first loaded.

One way you can use this event is to update your app's UI so users can view all the content in `SinglePane` mode. For example, the example app has a primary pane (the image) and an info pane.

> *Tall mode*

When there's only enough space to display one pane, you can move the content of `Pane2` into `Pane1` so the user can scroll to see all the content. It looks like this.



SinglePane mode

Remember that the `MinWideModeWidth` and `MinTallModeHeight` properties determine when the display mode changes, so you can change when the content is moved between panes by adjusting the values of these properties.

Here's the `ModeChanged` event handler code that moves the content between `Pane1` and `Pane2`. It also sets a VisualState to constrain the width of the image in Wide mode.

C#

```
private void TwoPaneView_ModeChanged(Microsoft.UI.Xaml.Controls.TwoPaneView
sender, object args)
{
    // Remove details content from it's parent panel.
    ((Panel)DetailsContent.Parent).Children.Remove(DetailsContent);
    // Set Normal visual state.
    Windows.UI.Xaml.VisualStateManager.GoToState(this, "Normal", true);

    // Single pane
    if (sender.Mode ==
Microsoft.UI.Xaml.Controls.TwoPaneViewMode.SinglePane)
    {
        // Add the details content to Pane1.
        Pane1StackPanel.Children.Add(DetailsContent);
```

```
    }
    // Dual pane.
    else
    {
        // Put details content in Pane2.
        Pane2Root.Children.Add(DetailsContent);

        // If also in Wide mode, set Wide visual state
        // to constrain the width of the image to 2*.
        if (sender.Mode == Microsoft.UI.Xaml.Controls.TwoPaneViewMode.Wide)
        {
            Windows.UI.Xaml.VisualStateManager.GoToState(this, "Wide",
true);
        }
    }
}
```

Dos and don'ts

- Do use the two-pane view whenever you can so that your app can take advantage of dual-screens and large screens.
- Don't put a two-pane view inside another two-pane view.

Progress controls

Article • 02/26/2025

A progress control provides feedback to the user that a long-running operation is underway. It can mean that the user cannot interact with the app when the progress indicator is visible, and can also indicate how long the wait time might be, depending on the indicator used.

Types of progress

There are two controls to show the user that an operation is underway – either through a ProgressBar or through a ProgressRing. Both ProgressBar and ProgressRing have two states that communicate if the user can interact with the application or not.

- The *determinate* state for both ProgressBar and ProgressRing shows the percentage completed of a task. This should be used during an operation whose duration is known, but its progress should not block the user's interaction with the app.
- The *indeterminate* state for ProgressBar shows that an operation is underway, does not block user interaction with the app, and its completion time is unknown.
- The *indeterminate* state for ProgressRing shows that an operation is underway, blocks user interaction with the app, and its completion time is unknown.

Additionally, a progress control is read only and not interactive. Meaning that the user cannot invoke or use these controls directly.

Expand table

Control	Display
Indeterminate ProgressBar	
Determinate ProgressBar	

Control	Display
Indeterminate ProgressRing	
Determinate ProgressRing	
Is this the right control?

It's not always obvious what control or what state (determinate vs indeterminate) to use when trying to show something is happening. Sometimes a task is obvious enough that it doesn't require a progress control at all – and sometimes even if a progress control is used, a line of text is still necessary in order to explain to the user what operation is underway.

ProgressBar

- **Does the control have a defined duration or predictable end?**

  Use a determinate ProgressBar then, and update the percentage or value accordingly.

- **Can the user continue without having to monitor the operation's progress?**

  When a ProgressBar is in use, interaction is non-modal, typically meaning that the user is not blocked by that operation's completion, and can continue to use the app in other ways until that aspect has completed.

- **Keywords**

  If your operation falls around these keywords, or if you're showing text that alongside the progress operation that matches these keywords; consider using a ProgressBar:
  - *Loading...*

- *Retrieving*
- *Working...*

ProgressRing

- **Will the operation cause the user to wait to continue?**

  If an operation requires all (or a large portion of) interaction with the app to wait until it has been completed, then the indeterminate ProgressRing is the better choice.
  - **Does the control have a defined duration or predictable end?**

  Use a determinate ProgressRing if you want the visual to be a ring instead of a bar, and update the percentage or value accordingly.

- **Is the app waiting for the user to complete a task?**

  If so, use an indeterminate ProgressRing, as they're meant to indicate an unknown wait time for the user.

- **Keywords**

  If your operation falls around these keywords, or if you're showing text alongside the progress operation that matches these keywords; consider using a ProgressRing:
  - *Refreshing*
  - *Signing in...*
  - *Connecting...*

No progress indication necessary

- **Does the user need to know that something is happening?**

  For example, if the app is downloading something in the background and the user didn't initiate the download, the user doesn't necessarily need to know about it.

- **Is the operation a background activity that doesn't block user activity and is of minimal (but still some) interest to the user?**

  Use text when your app is performing tasks that don't have to be visible all the time, but you still need to show the status.

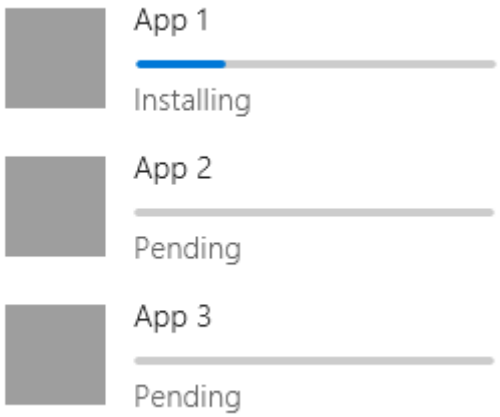
- **Does the user only care about the completion of the operation?**

> Sometimes it's best to show a notice only when the operation is completed, or give a visual that the operation has been completed immediately, and run the finishing touches in the background.

Progress controls best practices

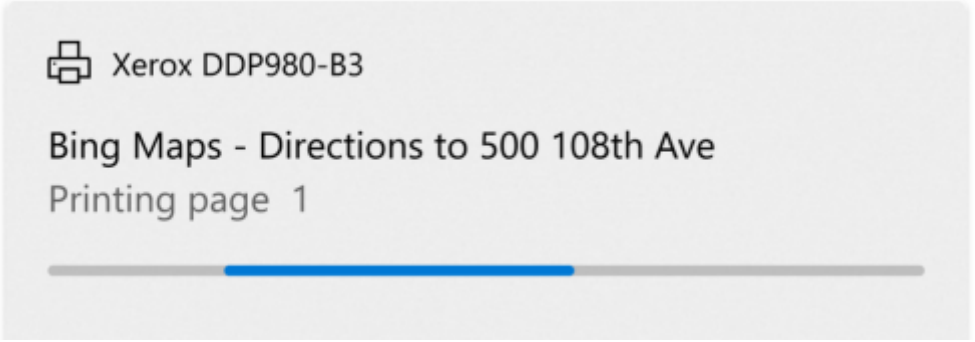
Sometimes it's best to see some visual representations of when and where to use these different progress controls:

ProgressBar - Determinate



The first example is the determinate ProgressBar. When the duration of the operation is known, when installing, downloading, setting up, etc; a determinate ProgressBar is best.

ProgressBar - Indeterminate

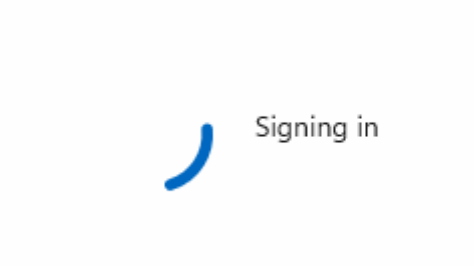


When it is not known how long the operation will take, use an indeterminate ProgressBar. Indeterminate ProgressBars are also good when filling a virtualized list, and creating a smooth visual transition between an indeterminate to determinate ProgressBar.

- **Is the operation in a virtualized collection?**

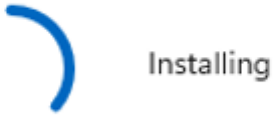
If so, do not put a progress indicator on each list item as they appear. Instead, use a ProgressBar and place it at the top of the collection of items being loaded in, to show that the items are being fetched.

ProgressRing - Indeterminate



The indeterminate ProgressRing is used when any further user interaction with the app is halted, or the app is waiting for the user's input to continue. The "signing in..." example above is a perfect scenario for the ProgressRing, the user cannot continue using the app until the sign is has completed.

ProgressRing - Determinate



When the duration of the operation is known and the ring visual is desired, when installing, downloading, setting up, etc; a determinate ProgressRing is best.

Create a progress control

✔ **Important APIs:** ProgressBar class, IsIndeterminate property, ProgressRing class, IsActive property

Open the WinUI 3 Gallery app and see the **ProgressBar** or **ProgressRing**.

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

Both progress controls are rather simple; but some visual features of the controls are not obvious to customize.

Sizing the ProgressRing

The ProgressRing can be sized as large as you want, but can only be as small as 20x20epx. In order to resize a ProgressRing, you must set its height and width. If only height or width are set, the control will assume minimum sizing (20x20epx) – conversely if the height and width are set to two different sizes, the smaller of the sizes will be assumed. To ensure your ProgressRing is correct for your needs, set both the height and the width to the same value:

XAML

```
<ProgressRing Height="100" Width="100"/>
```

To make your ProgressRing visible, and animate, you must set the IsActive property to true:

XAML

```
<ProgressRing IsActive="True" Height="100" Width="100"/>
```

C#

```
progressRing.IsActive = true;
```

Coloring the progress controls

By default, the main coloring of the progress controls is set to the accent color of the system. To override this brush simply change the foreground property on either control.

XAML

```
<ProgressRing IsActive="True" Height="100" Width="100" Foreground="Blue"/>
<ProgressBar Width="100" Foreground="Green"/>
```

Changing the foreground color for the ProgressRing will change the fill color of the ring. The foreground property for the ProgressBar will change the fill color of the bar – to alter the unfilled portion of the bar, simply override the background property.

Showing a wait cursor

Sometimes it's best to just show a brief wait cursor, when the app or operation needs time to think, and you need to indicate to the user that the app or area where the wait cursor is visible should not be interacted with until the wait cursor has disappeared.

```
C#

Window.Current.CoreWindow.PointerCursor = new
Windows.UI.Core.CoreCursor(Windows.UI.Core.CoreCursorType.Wait, 10);
```

UWP and WinUI 2

> **ⓘ Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

The progress controls for UWP apps are included as part of WinUI 2. For more info, including installation instructions, see WinUI 2. APIs for this control exist in both the Windows.UI.Xaml.Controls and Microsoft.UI.Xaml.Controls namespaces.

- ✓ **UWP APIs:** ProgressBar class, IsIndeterminate property, ProgressRing class, IsActive property
- ✓ **WinUI 2 Apis:** ProgressBar class, IsIndeterminate property, ProgressRing class, IsActive property
- ✓ Open the WinUI 2 Gallery app and see the ProgressBar or ProgressRing. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles, templates, and features for all controls. WinUI 2.2 or later includes a new template for this control that uses rounded corners. For more info, see Corner radius.

To use the code in this article with WinUI 2, use an alias in XAML (we use `muxc`) to represent the Windows UI Library APIs that are included in your project. See Get Started with WinUI 2 for more info.

XAML

```
xmlns:muxc="using:Microsoft.UI.Xaml.Controls"

<muxc:ProgressBar />
<muxc:ProgressRing />
```

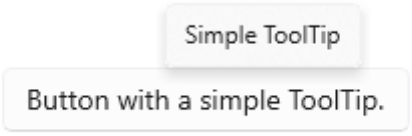
Tooltips

Article • 02/26/2025

A tooltip is a popup that contains additional information about another control or object. Tooltips display automatically when the user moves focus to, presses and holds, or hovers the pointer over the associated control. The tooltip disappears when the user moves focus from, stops pressing on, or stops hovering the pointer over the associated control (unless the pointer is moving towards the tooltip).

> **Note**
>
> Starting with Windows 11 version 21H2, a tooltip can also be dismissed by pressing the CTRL key.



Is this the right control?

Use a tooltip to reveal more info about a control before asking the user to perform an action. Tooltips should be used sparingly, and only when they are adding distinct value for the user who is trying to complete a task. One rule of thumb is that if the information is available elsewhere in the same experience, you do not need a tooltip. A valuable tooltip will clarify an unclear action.

When should you use a tooltip? To decide, consider these questions:

- **Should info become visible based on pointer hover?** If not, use another control. Display tips only as the result of user interaction, never display them on their own.
- **Does a control have a text label?** If not, use a tooltip to provide the label. It is a good UX design practice to label most controls inline and for these you don't need tooltips. Toolbar controls and command buttons showing only icons need tooltips.
- **Does an object benefit from a description or further info?** If so, use a tooltip. But the text must be supplemental — that is, not essential to the primary tasks. If it is essential, put it directly in the UI so that users don't have to discover or hunt for it.

- **Is the supplemental info an error, warning, or status?** If so, use another UI element, such as a flyout.
- **Do users need to interact with the tip?** If so, use another control. Users can't interact with tips because moving the mouse makes them disappear.
- **Do users need to print the supplemental info?** If so, use another control.
- **Will users find the tips annoying or distracting?** If so, consider using another solution — including doing nothing at all. If you do use tips where they might be distracting, allow users to turn them off.

Recommendations

- Use tooltips sparingly (or not at all). Tooltips are an interruption. A tooltip can be as distracting as a pop-up, so don't use them unless they add significant value.
- Keep the tooltip text concise. Tooltips are perfect for short sentences and sentence fragments. Large blocks of text can be overwhelming and the tooltip may time out before the user has finished reading.
- Create helpful, supplemental tooltip text. Tooltip text must be informative. Don't make it obvious or just repeat what is already on the screen. Because tooltip text isn't always visible, it should be supplemental info that users don't have to read. Communicate important info using self-explanatory control labels or in-place supplemental text.
- Use images when appropriate. Sometimes it's better to use an image in a tooltip. For example, when the user hovers over a hyperlink, you can use a tooltip to show a preview of the linked page.
- Keyboard accelerators are displayed in tooltips by default. If you add your own tooltip, make sure that it includes information about the keyboard accelerators which are available.
- Don't use a tooltip to display text already visible in the UI. For example, don't put a tooltip on a button that shows the same text of the button.
- Don't put interactive controls inside the tooltip.
- Don't put images that look like they are interactive inside the tooltip.

Create a tooltip

✓ **Important APIs:** ToolTip class, ToolTipService class

Open the WinUI 3 Gallery app and see the ToolTip in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

A ToolTip must be assigned to another UI element that is its owner. The ToolTipService class provides static methods to display a ToolTip.

In XAML, use the **ToolTipService.Tooltip** attached property to assign the ToolTip to an owner.

XAML

```
<Button Content="New" ToolTipService.ToolTip="Create a new document"/>
```

In code, use the ToolTipService.SetToolTip method to assign the ToolTip to an owner.

XAML

```
<Button x:Name="submitButton" Content="New"/>
```

C#

```
ToolTip toolTip = new ToolTip();
toolTip.Content = "Create a new document";
ToolTipService.SetToolTip(submitButton, toolTip);
```

Content

You can use any object as the Content of a ToolTip. Here's an example of using an Image in a ToolTip.

XAML

```
<TextBlock Text="store logo">
    <ToolTipService.ToolTip>
        <Image Source="Assets/StoreLogo.png"/>
    </ToolTipService.ToolTip>
</TextBlock>
```

Placement

By default, a ToolTip is displayed centered above the pointer. The placement is not constrained by the app window, so the ToolTip might be displayed partially or completely outside of the app window bounds.

For broad adjustments, use the Placement property or **ToolTipService.Placement** attached property to specify whether the ToolTip should draw above, below, left, or right of the pointer. You can set the VerticalOffset or HorizontalOffset properties to change the distance between the pointer and the ToolTip. Only one of the two offset values will influence the final position - VerticalOffset when Placement is Top or Bottom, HorizontalOffset when Placement is Left or Right.

XAML

```
<!-- An Image with an offset ToolTip. -->
<Image Source="Assets/StoreLogo.png">
    <ToolTipService.ToolTip>
        <ToolTip Content="Offset ToolTip."
                 Placement="Right"
                 HorizontalOffset="20"/>
    </ToolTipService.ToolTip>
</Image>
```

If a ToolTip obscures the content it is referring to, you can adjust its placement precisely using the **PlacementRect** property. PlacementRect anchors the ToolTip's position and also serves as an area that ToolTip will not occlude, provided there's sufficient screen space to draw ToolTip outside this area. You can specify the origin of the rectangle relative to the ToolTip's owner, and the height and width of the exclusion area. The Placement property will define if ToolTip should draw above, below, left, or right of the PlacementRect.

XAML

```
<!-- An Image with a non-occluding ToolTip. -->
<Image Source="Assets/StoreLogo.png" Height="64" Width="96">
    <ToolTipService.ToolTip>
        <ToolTip Content="Non-occluding ToolTip."
                 PlacementRect="0,0,96,64"/>
    </ToolTipService.ToolTip>
</Image>
```

UWP and WinUI 2

ⓘ Important

The information and examples in this article are optimized for apps that use the **Windows App SDK** and **WinUI 3**, but are generally applicable to UWP apps that use **WinUI 2**. See the UWP API reference for platform specific information and examples.

This section contains information you need to use the control in a UWP or WinUI 2 app.

APIs for this control exist in the Windows.UI.Xaml.Controls namespace.

- ✓ **UWP APIs:** ToolTip class, ToolTipService class
- ✓ Open the WinUI 2 Gallery app and see the ToolTip in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles and templates for all controls. WinUI 2.2 or later includes a new template for this control that uses rounded corners. For more info, see Corner radius.

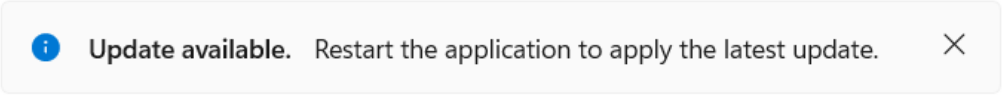
InfoBar

Article • 02/26/2025

The InfoBar control is for displaying app-wide status messages to users that are highly visible yet non-intrusive. There are built-in Severity levels to easily indicate the type of message shown as well as the option to include your own call to action or hyperlink button. Since the InfoBar is inline with other UI content the option is there for the control to always be visible or dismissed by the user.



Is this the right control?

Use an InfoBar control when a user should be informed of, acknowledge, or take action on a changed application state. By default the notification will remain in the content area until closed by the user but will not necessarily break user flow.

An InfoBar will take up space in your layout and behave like any other child elements. It will not cover up other content or float on top of it.

Do not use an InfoBar control to confirm or respond directly to a user action that doesn't change the state of the app, for time-sensitive alerts, or for non-essential messages.

Remarks

Use an InfoBar that is closed by the user or when the status is resolved for scenarios that **directly** impact app perception or experience.

Here are some examples:

- Internet connectivity lost
- Error while saving a document when triggered automatically, not related to specific user action
- No microphone plugged in when attempting to record

- The subscription to the application is expired

Use an InfoBar that is closed by the user for scenarios that **indirectly** impact app perception or experience

Here are some examples:

- A call has begun recording
- Update applied with link to 'Release Notes'
- The terms of service have been updated and require acknowledgement
- An app-wide backup has successfully, asynchronously completed
- The subscription to the application is close to expiring

When should a different control be used?

There are some scenarios where a ContentDialog, Flyout, or TeachingTip may be more appropriate to use.

- For scenarios where a persistent notification is not needed, e.g. displaying information in context of a specific UI element, a Flyout is a better option.
- For scenarios where the application is confirming a user action, showing information the user ***must*** read, use a ContentDialog.
  - Additionally, if a status change to the app is so severe that it needs to block all further ability for the user to interact with the app, use a ContentDialog.
- For scenarios where a notification is a transient teaching moment, a TeachingTip is a better option.

For more info about choosing the right notification control, see the Dialogs and Flyouts article.

Recommendations

Enter and Exit Usability

Flashing content

The InfoBar should not appear and disappear from view rapidly to prevent flashing on the screen. Avoid flashing visuals for people with photosensitivities and to improve the usability of your application.

For InfoBars that automatically enter and exit the view via an app status condition, we recommend you include logic in your application to prevent content from appearing or

disappearing rapidly or multiple times in a row. However, in general, this control should be used for long-lived status messages.

Updating the InfoBar

Once the control is open, any changes made to the various properties like updating the message or Severity will not raise a notification event. If you would like to inform users that use screen readers of the InfoBar's updated content we recommend you close and re-open the control to trigger the event.

Inline messages offsetting content

For InfoBars that are inline with other UI content, keep in mind how the rest of the page will responsively react to the addition of the element.

InfoBars with a substantial height could dramatically alter the layout of the other elements on the page. If the InfoBar appears or disappears rapidly, especially in succession, the user may be confused with the changing visual state.

Color and Icon

When customizing the color and icon outside of the preset Severity levels, keep in mind user expectations for the connotations from the set of standard icons and colors.

Additionally, the preset Severity colors have already been designed for theme changes, high-contrast mode, color confusion accessibility, and contrast with foreground colors. We recommend to use these colors when possible and to include custom logic in your application to adapt to the various color states and accessibility features.

Please view the UX guidance for Standard Icons and Color to ensure your message is communicated clearly and accessible to users.

Severity

Avoid setting the Severity property for a notification that does not match the information communicated in the Title, Message, or custom content.

The accompanying information should aim to communicate the following to use that Severity.

- Error: An error or problem that has occurred.
- Warning: A condition that might cause a problem in the future.

- Success: A long-running and/or background task has completed.
- Default: General information that requires the user's attention.

Icons and color should not be the only UI components signifying meaning for your notification. Text in the notification's Title and/or Message should be included to display information.

Message

Text in your notification will not be a constant length in all languages. For the Title and Message property this may impact whether your notification will expand to a second line. We recommend you avoid positioning based on message length or other UI elements set to a specific language.

The notification will follow standard mirroring behavior when localized to/from languages that are right to left (RTL) or left to right (LTR). The icon will only mirror if there is directionality.

Please view the guidance for Adjust layout and fonts, and support RTL for more information about text localization in your notification.

Create an InfoBar

✓ **Important APIs:** InfoBar class

Open the WinUI 3 Gallery app and see the InfoBar in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

The XAML below describes an inline InfoBar with the default styling for an informational notification. An info bar can be placed like any other element and will follow base layout behavior. For example, in a vertical StackPanel, the InfoBar will horizontally expand to fill the available width.

By default, the InfoBar will not be visible. Set the IsOpen property to true in the XAML or code behind to display the InfoBar.

XAML

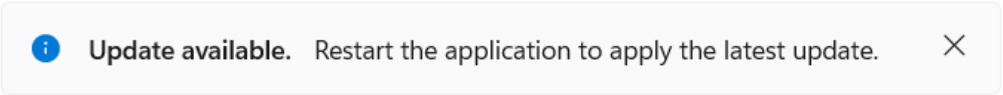
```
<InfoBar x:Name="UpdateAvailableNotification"
    Title="Update available."
```

```
    Message="Restart the application to apply the latest update.">
</InfoBar>
```

C#

```
public MainPage()
{
    this.InitializeComponent();

    if(IsUpdateAvailable())
    {
        UpdateAvailableNotification.IsOpen = true;
    }
}
```

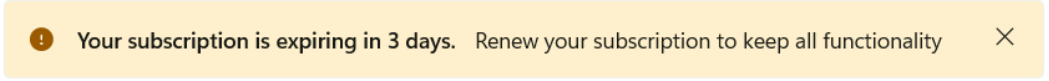


Using pre-defined severity levels

The type of the info bar can be set via the Severity property to automatically set a consistent status color, icon, and assistive technology settings dependent on the criticality of the notification. If no Severity is set, the default informational styling is applied.

XAML

```
<InfoBar x:Name="SubscriptionExpiringNotification"
    Severity="Warning"
    Title="Your subscription is expiring in 3 days."
    Message="Renew your subscription to keep all functionality" />
```



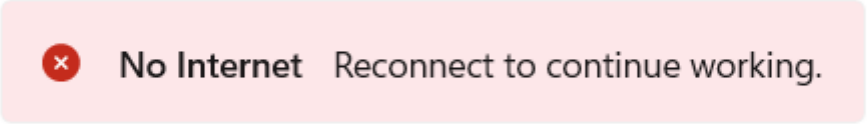
Programmatic close in InfoBar

An InfoBar can be closed by the user via the close button or programmatically. If the notification is required to be in view until the status is resolved and you would like to remove the ability for the user to close the info bar, you can set the IsClosable property to false.

The default value of this property is true, in which case the close button is present and takes the form of an 'X'.

XAML

```
<InfoBar x:Name="NoInternetNotification"
    Severity="Error"
    Title="No Internet"
    Message="Reconnect to continue working."
    IsClosable="False" />
```



Customization: Background color and icon

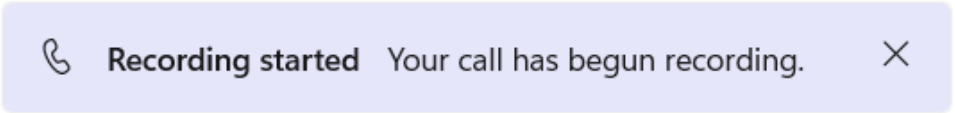
Outside of the pre-defined severity levels, the Background and IconSource properties can be set to customize the icon and background color. The InfoBar will retain the assistive technology settings of the severity defined, or default if none was defined.

A custom background color can be set via the standard Background property and will override the color set by Severity. Please keep in mind content readability and accessibility when setting your own color.

A custom icon can be set via the IconSource property. By default, an icon will be visible (assuming the control isn't collapsed). This icon can be removed by setting the IsIconVisible property to false. For custom icons, the recommended icon size is 20px.

XAML

```
<InfoBar x:Name="CallRecordingNotification"
    Title="Recording started"
    Message="Your call has begun recording."
    Background="{StaticResource LavenderBackgroundBrush}">
    <InfoBar.IconSource>
        <SymbolIconSource Symbol="Phone" />
    </InfoBar.IconSource>
</InfoBar>
```

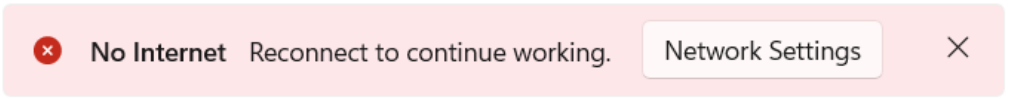


Add an action button

An additional action button can be added by defining your own button that inherits ButtonBase and setting it in the ActionButton property. Custom styling will be applied to action buttons of type Button and HyperlinkButton for consistency and accessibility. Aside from the ActionButton property, additional action buttons can be added via custom content and will appear below the message.

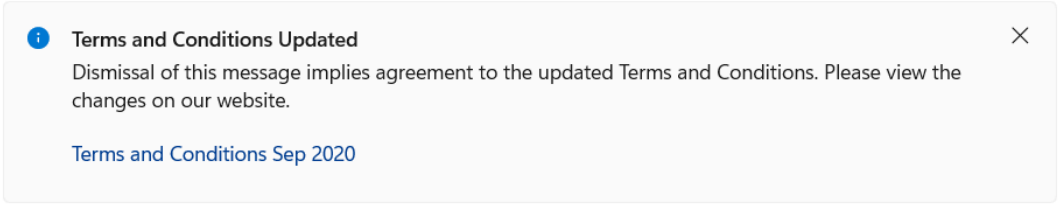
XAML

```
<InfoBar x:Name="NoInternetNotification"
    Severity="Error"
    Title="No Internet"
    Message="Reconnect to continue working.">
    <InfoBar.ActionButton>
        <Button Content="Network Settings"
Click="InternetInfoBarButton_Click" />
    </InfoBar.ActionButton>
</InfoBar>
```



XAML

```
<InfoBar x:Name="TermsAndConditionsUpdatedNotification"
    Title="Terms and Conditions Updated"
    Message="Dismissal of this message implies agreement to the updated
Terms and Conditions. Please view the changes on our website.">
    <InfoBar.ActionButton>
        <HyperlinkButton Content="Terms and Conditions Sep 2020"
            NavigateUri="https://www.example.com"
            Click="UpdateInfoBarHyperlinkButton_Click" />
    </InfoBar.ActionButton>
</InfoBar>
```



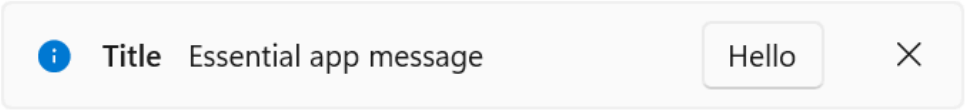
Right-aligned action button

By default, the action button is left-aligned in the available space directly to the right of the Message. Optionally, you can set HorizontalAlignment to "right" in your button to align this button to be directly to the left of the close button in the single line, horizontal, layout.

XAML

```
<InfoBar x:Name="RightAlignedButtonNotification"
    Title="Title"
    Message="Essential app message">
    <InfoBar.ActionButton>
        <Button Content="Hello" HorizontalAlignment="Right"/>
```

```
    </InfoBar.ActionButton>
</InfoBar>
```

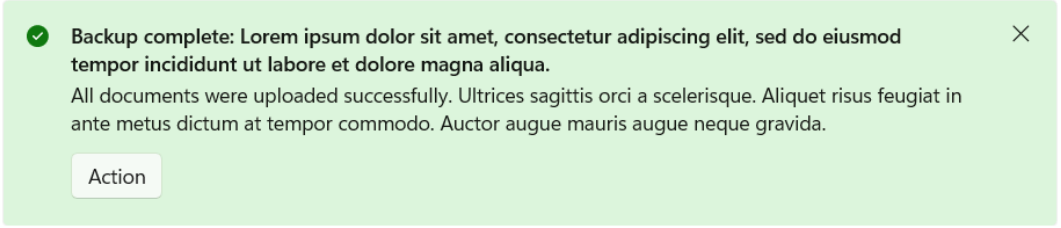


Content wrapping

If the InfoBar content, excluding custom content, is unable to fit on a single horizontal line they will be laid out vertically. The Title, Message, and ActionButton — if present — will each appear on separate lines.

XAML

```
<InfoBar x:Name="BackupCompleteNotification"
    Severity="Success"
    Title="Backup complete: Lorem ipsum dolor sit amet, consectetur
adipiscing elit, sed do eiusmod tempor incididunt ut labore et dolore magna
aliqua."
    Message="All documents were uploaded successfully. Ultrices sagittis
orci a scelerisque. Aliquet risus feugiat in ante metus dictum at tempor
commodo. Auctor augue mauris augue neque gravida.">
    <InfoBar.ActionButton>
        <Button Content="Action"
            Click="BackupInfoBarButton_Click" />
    </InfoBar.ActionButton>
</InfoBar>
```

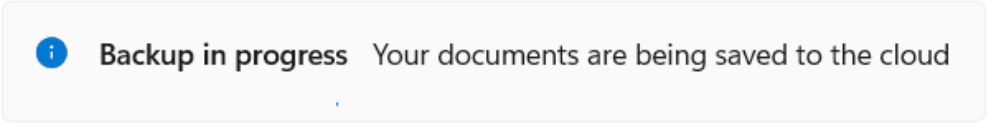


Custom content

XAML content can be added to an InfoBar using the Content property. It will appear in its own line below the rest of the control content. The InfoBar will expand to fit the content defined.

XAML

```
<InfoBar x:Name="BackupInProgressNotification"
    Title="Backup in progress"
    Message="Your documents are being saved to the cloud"
    IsClosable="False">
    <InfoBar.Content>
        <ProgressBar IsIndeterminate="True" Margin="0,0,0,6"
MaxWidth="200"/>
    </InfoBar.Content>
</InfoBar>
```



Lightweight styling

You can modify the default Style and ControlTemplate to give the control a unique appearance. See the Control Style and Template section of the InfoBar API docs for a list of the available theme resources.

For more info, see the Light-weight styling section of the Styling controls article.

For example, the following causes the background color for all informational InfoBars on a page to be blue:

XAML

```
<Page.Resources>
    <x:SolidColorBrush x:Key="InfoBarInformationalSeverityBackgroundBrush"
Color="LightBlue"></x:SolidColorBrush>
</Page.Resources>
```

Canceling close

The Closing event can be used to cancel and/or defer the close of an InfoBar. This can be used to keep the InfoBar open or allow time for a custom action to occur. When the closing of an InfoBar is canceled, IsOpen will go back to true. A programmatic close can also be canceled.

XAML

```
<InfoBar x:Name="UpdateAvailable"
    Title="Update Available"
    Message="Please close this tip to apply required security updates to
this application"
    Closing="InfoBar_Closing">
</InfoBar>
```

C#

```
public void InfoBar_Closing(InfoBar sender, InfoBarClosingEventArgs args)
{
    if (args.Reason == InfoBarCloseReason.CloseButton)
    {
        if (!ApplyUpdates())
        {
            // could not apply updates - do not close
            args.Cancel = true;
        }
    }
}
```

UWP and WinUI 2

> **ⓘ Important**
>

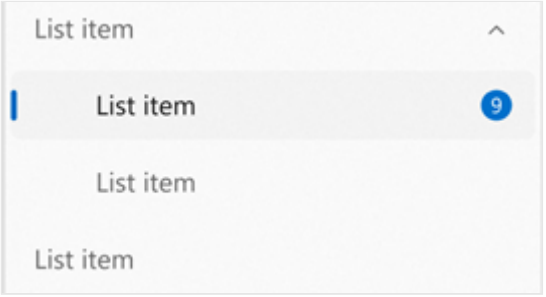
Info badge

Article • 02/26/2025

Badging is a non-intrusive and intuitive way to display notifications or bring focus to an area within an app - whether that be for notifications, indicating new content, or showing an alert. An info badge is a small piece of UI that can be added into an app and customized to display a number, icon, or a simple dot.

The info badge is built into the XAML navigation view, but can also be placed as a standalone element in the XAML tree, allowing you to place an info badge into any control or piece of UI of your choosing. When you use an info badge somewhere other than navigation view, you are responsible for programmatically determining when to show and dismiss the info badge, and where to place the info badge.



Is this the right control?

An info badge should be used when you want to bring the user's focus to a certain area of your app in an unintrusive way. When an info badge appears, it is meant to bring focus to an area and then let the user get back into their flow, giving them the choice of whether or not to look into the details of why the info badge appeared. Info badges should only represent messages that are dismissible and non-permanent – an info badge should have specific rules as to when it can appear, disappear, and change.

Examples of appropriate info badge usage:

- To indicate new messages have arrived.
- To indicate new articles are available to read.
- To indicate that there are new options available on a page.
- To indicate that there might be an issue with an item on a certain page that does not block the app from functioning.

When should a different control be used?

An info badge should not be used to display critical errors or convey highly important messages that need immediate action. Info badges should not be used in cases where they need to be interacted with immediately to continue using the app.

Examples of inappropriate info badge usage:

- To indicate an urgent matter on a page within the app that needs to be addressed before continuing to use the app. For this scenario, use a content dialog.
- Appearing in an app with no way for the user to dismiss the info badge. For a persistent alert like this, use an info bar.
- Using the info badge as a permanent way of bringing the user's focus to an area, without a way for the user to dismiss the info badge.
- Using an info badge as a regular icon or image in your app. Instead, use an appropriate image or icon (see IconElement and IconSource).

Types of info badges

There are three styles of info badge that you can choose from - *dot*, *icon*, and *numeric*, as shown in order below.

Dot info badge

The dot info badge is a simple ellipse with a diameter of 4px. It has no border, and is not meant to hold text or anything else inside of it.

You should use the dot info badge for general scenarios in which you want to guide the user's focus towards the info badge – for example, to indicate new content or updates are available.

Icon info badge

The icon info badge is an ellipse with a diameter of 16px that holds an icon inside of it. The info badge has an IconSource property that provides flexibility for the types of supported icons.

You should use the icon info badge to send a quick message along with getting the user's attention – for example, to alert the user that something non-blocking has gone wrong, an extra important update is available, or that something specific in the app is currently enabled (such as a countdown timer going).

If you'd like to use a BitmapIconSource for the `IconSource` of your info badge, you are responsible for ensuring that the bitmap fits inside of the info badge (either by changing the size of the icon, or changing the size of the info badge).

Numeric info badge

The numeric info badge is the same shape and size as the icon info badge, but it holds a number inside of it, determined by the Value property. Numbers must be whole integers and must be greater than or equal to zero. The width of the info badge will automatically expand as the number being displayed grows to multiple digits, with a smooth animation.

You should use the numeric info badge to show that there are a specific number of items that need attention – for example, new emails or messages.

Preset info badge styles

To help support the most common scenarios in which info badges are used, the control includes built-in preset info badge styles. While you can customize your info badge to use any color/icon/number combination that you want, these built-in presets are a quick option to make sure that your info badge is compliant with accessibility guidelines and is proportional in terms of icon and number sizing.

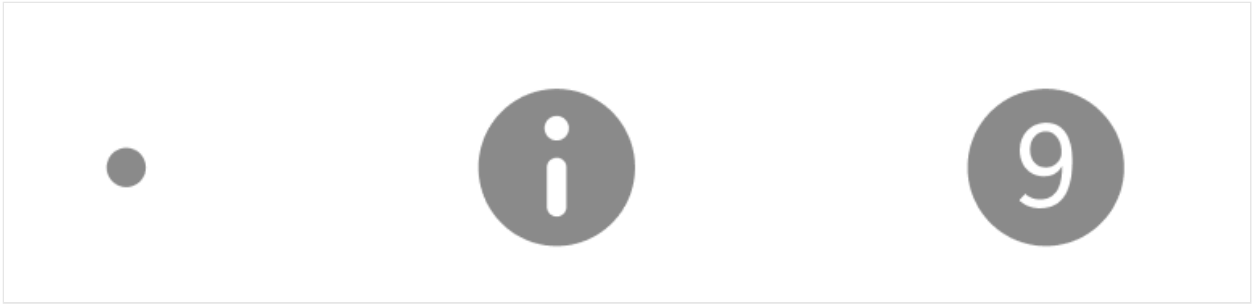
The following style presets are available for info badges:

Attention

- `AttentionDotInfoBadgeStyle`
- `AttentionIconInfoBadgeStyle`
- `AttentionValueInfoBadgeStyle`

Informational

- `InformationalDotInfoBadgeStyle`
- `InformationalIconInfoBadgeStyle`
- `InformationalValueInfoBadgeStyle`



Success

- `SuccessDotInfoBadgeStyle`
- `SuccessIconInfoBadgeStyle`
- `SuccessValueInfoBadgeStyle`

Caution

- `CautionDotInfoBadgeStyle`
- `CautionIconInfoBadgeStyle`
- `CautionValueInfoBadgeStyle`

Critical

- `CriticalDotInfoBadgeStyle`

- `CriticalIconInfoBadgeStyle`
- `CriticalValueInfoBadgeStyle`

If a style is set on an info badge and a conflicting property is also set, the property will overwrite the conflicting part of the style, but non-conflicting style elements will stay applied.

For example, if you apply the `CriticalIconInfoBadgeStyle` to an info badge, but also set `InfoBadge.Value = "1"`, you would end up with an info badge that has the "Critical" background color but displays the number 1 inside of it, rather than displaying the preset icon.

This example creates an info badge that takes on the color and icon of the *Attention Icon* preset style.

XAML

```
<InfoBadge Style="{ThemeResource AttentionIconInfoBadgeStyle}"/>
```

Accessibility

The info badge control does not have any screen reader functionality or user interface automation (UIA) built-in to it on its own, as the control is not focusable and cannot be interacted with.

If you're using an info badge inside of a navigation view, the navigation view provides built-in screen reader and assistive technology support. When you're tabbing through a navigation view and you land on a navigation view item with an info badge on it, the screen reader will announce that there is an info badge on this item. If the info badge in question is numeric, the screen reader will announce the info badge's value as well.

If you are using an info badge outside of a navigation view, we recommend the following to ensure your app is fully accessible:

- The parent element of the info badge should be focusable and accessible by tab.
- The parent element announces the info badge to screen readers.
- The app sends a UIA notification when the info badge appears for the first time.
- The app sends a UIA notification when an info badge disappears from the UI.
- The app sends a UIA notification when a significant change has occurred with an existing info badge.
    - The definition of "significant change" is up to you as the individual developer. Examples of this can include: an info badge switching between different types, an info badge changing color to represent its status, or an info badge's value exceeding a certain significant number.

To control what the parent element announces to screen readers, you can use attached properties of the AutomationProperties class. For an info badge, it's recommended that you set either the `AutomationProperties.FullDescription` or `AutomationProperties.ItemStatus` attached properties on the parent element.

To send UIA notifications upon the info badge's appearance or dismissal, you can use the AutomationPeer.RaiseAutomationEvent method.

The info badge comes at a default size that meets accessibility requirements. You can customize many aspects of the info badge including its height/width/color, etc., but it's important that the default info badge adheres to our accessibility guidelines for size and color.

Create an InfoBadge

>
> Some information relates to prerelease product that may be substantially modified before it's released. Microsoft makes no warranties, express or implied, with respect to the information provided here.

✓ **Important APIs:** InfoBadge class, IconSource property, Value property

Open the WinUI 3 Gallery app and see the InfoBadge in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source

> code on GitHub

You can create an InfoBadge in XAML or in code. The kind of InfoBadge you create is determined by which properties you set.

Dot

To create a dot InfoBadge, use a default InfoBadge control with no properties set.

XAML

```
<InfoBadge />
```

Icon

To create an icon InfoBadge, set the IconSource property.

XAML

```
<InfoBadge x:Name="SyncStatusInfoBadge">
    <InfoBadge.IconSource>
        <SymbolIconSource Symbol="Sync"/>
    </InfoBadge.IconSource>
</InfoBadge>
```

Numeric

To create a numeric InfoBadge, set the Value property.

XAML

```
<InfoBadge x:Name="EmailInfoBadge" Value="{x:Bind numUnreadMail}"/>
```

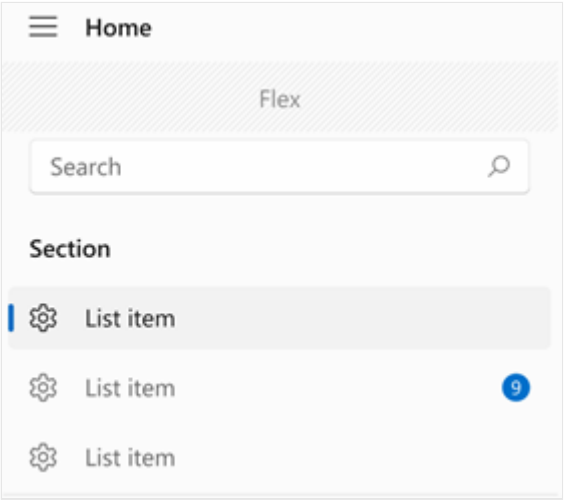
In most scenarios, you'll bind the `Value` property of the InfoBadge to a changing integer value in your app's backend so you can easily increment/decrement and show/hide the InfoBadge based on that specific value.

> ⓘ **Note**
>
> If both the `Icon` and `Value` properties are set, the `Value` property takes precedence and the InfoBadge appears as a numeric InfoBadge.

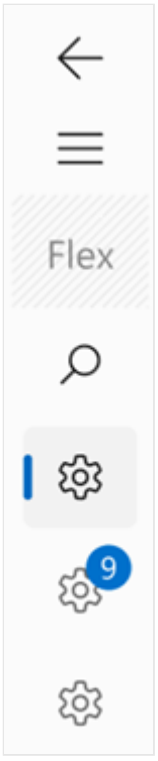
Using an InfoBadge in NavigationView

If you're using a NavigationView in your app, we recommend that you use an InfoBadge in the NavigationView to show app-wide notifications and alerts. To place the InfoBadge on a NavigationViewItem, assign the InfoBadge object to the `NavigationViewItem.InfoBadge` property.

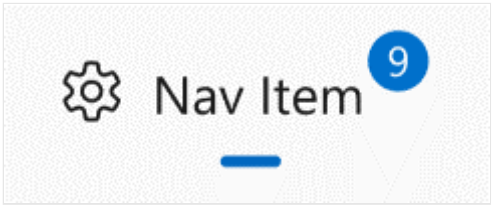
In Left-Expanded mode, the InfoBadge appears right-aligned to the edge of the NavigationViewItem.



In Left-Compact mode, the InfoBadge appears overlayed on the top right corner of the icon.



In Top mode, the InfoBadge is aligned to the upper right hand corner of the overall item.



We recommend that you not use different types of InfoBadges in one NavigationView, such as attaching a numeric InfoBadge to one NavigationViewItem and a dot InfoBadge to another NavigationViewItem in the same NavigationView.

Example: Incrementing a numeric InfoBadge in a NavigationView

This example simulates how an email app could use an InfoBadge in a NavigationView to display the number of new emails in the inbox, and increment the number shown in the InfoBadge when a new message is received.

XAML

```
<NavigationView SelectionChanged="NavigationView_SelectionChanged">
    <NavigationView.MenuItems>
        <NavigationViewItem Content="Home" Icon="Home"/>
        <NavigationViewItem Content="Account" Icon="Contact"/>
        <NavigationViewItem x:Name="InboxPage" Content="Inbox" Icon="Mail">
            <NavigationViewItem.InfoBadge>
```

```
                <InfoBadge x:Name="bg1"
                                Value="{x:Bind mailBox.NewMailCount,
Mode=OneWay}"
                                Visibility="{x:Bind mailBox.HasNewMail,
Mode=OneWay}"/>
            </NavigationViewItem.InfoBadge>
        </NavigationViewItem>
    </NavigationView.MenuItems>
    <Frame x:Name="contentFrame" />
</NavigationView>
```

C#

```
public sealed partial class MainWindow : Window
{
    MailBox mailBox = new MailBox();

    public MainWindow()
    {
        this.InitializeComponent();

    }

    private void NavigationView_SelectionChanged(NavigationView sender,
                                NavigationViewSelectionChangedEventArgs args)
    {
        if (args.SelectedItem == InboxPage)
        {
            mailBox.ResetNewMailCount();
        }
        else
        {
            mailBox.CheckMail();
        }
    }
}

public class MailBox : DependencyObject
{
    DispatcherQueueTimer timer;

    // Dependency Properties for binding.
    public int NewMailCount
    {
        get { return (int)GetValue(NewMailCountProperty); }
        set { SetValue(NewMailCountProperty, value); }
    }
    public static readonly DependencyProperty NewMailCountProperty =
        DependencyProperty.Register("NewMailCount", typeof(int),
typeof(MailBox), new PropertyMetadata(0));

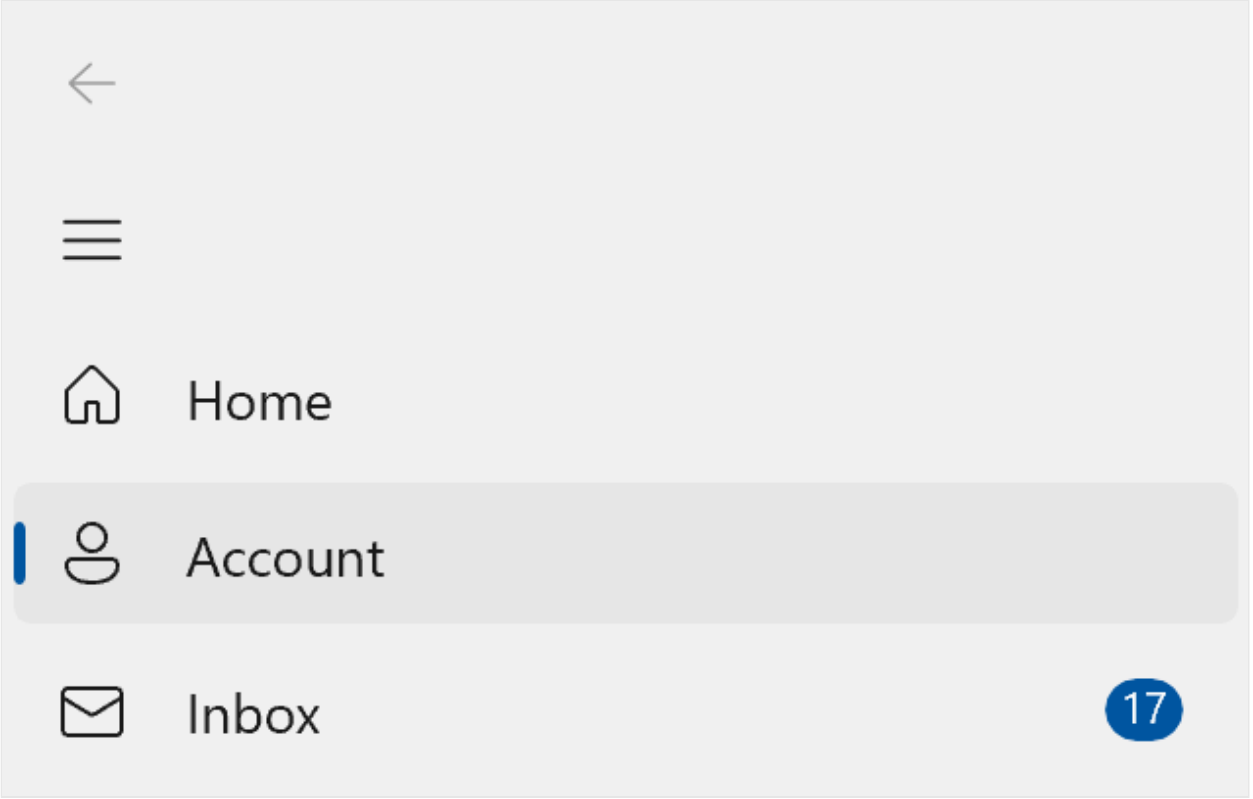
    public bool HasNewMail
    {
```

```
        get { return (bool)GetValue(HasNewMailProperty); }
        set { SetValue(HasNewMailProperty, value); }
    }
    public static readonly DependencyProperty HasNewMailProperty =
        DependencyProperty.Register("HasNewMail", typeof(bool),
typeof(MailBox), new PropertyMetadata(false));

    public MailBox()
    {
        timer = this.DispatcherQueue.CreateTimer();
        timer.Interval = new TimeSpan(15000000);
        timer.Tick += (s, e) =>
        {
            NewMailCount++;
            if (HasNewMail == false) { HasNewMail = true; }
        };
        timer.Start();
    }

    public void ResetNewMailCount()
    {
        NewMailCount = 0;
        HasNewMail = false;
        timer.Stop();
    }

    public void CheckMail()
    {
        timer.Start();
    }
}
```

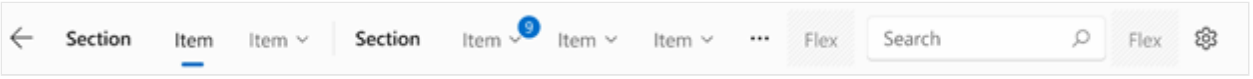


Hierarchy in NavigationView

If you have a hierarchical NavigationView, with NavigationViewItems nested in other NavigationViewItems, parent items will follow the same design/placement patterns as described above.

The parent NavigationViewItem and child NavigationViewItems will each have their own InfoBadge property. You can bind the value of the parent's InfoBadge to factors that determine the children's InfoBadge values, such as showing the sum of the children's numeric InfoBadges on the parent's InfoBadge.

This image shows a hierarchical NavigationView with its PaneDisplayMode set to Top, where the top-level (parent) item shows a numeric InfoBadge. The app has set the parent item InfoBadge to represent what's being displayed in the child items' InfoBadges, as the child items are currently not expanded (and therefore not visible).



Using an InfoBadge in another control

You might want to show alerts or notifications on elements within your app other than NavigationView. You might have a ListViewItem that needs special attention, or a menu item that displays a notification. In these cases, you can integrate InfoBadge directly into your UI with other controls.

InfoBadge is a UIElement and therefore cannot be used as a shared resource.

To do this, use InfoBadge as you would any other control – simply add the InfoBadge markup where you'd like it to appear. Since InfoBadge inherits from Control, it has all the built-in positioning properties, such as margin, alignment, padding, and more, which you can use to position your InfoBadge exactly where you want it.

If you place an InfoBadge inside of another control, such as a Button or a ListViewItem, it will likely get cropped if you position it to extend beyond the bounding box of the parent control. If your InfoBadge is inside of another control, it should not be positioned past the corners of the control's overall bounding box.

Example: Placing an InfoBadge inside another control

Here's a Button that has an InfoBadge placed in its upper right hand corner, with the badge layered on top of the content. This example can be applied to many controls

other than Button as well – it simply shows how to place, position, and show an InfoBadge inside of another WinUI control.

XAML

```
<Button Width="200" Height="60" Padding="4"
        HorizontalContentAlignment="Stretch"
VerticalContentAlignment="Stretch">
    <Grid>
        <SymbolIcon Symbol="Sync"/>
        <InfoBadge x:Name="buttonInfoBadge"
                        Background="#C42B1C"
                        HorizontalAlignment="Right"
                        VerticalAlignment="Top"
                        Width="16" Height="16">
            <InfoBadge.IconSource>
                <FontIconSource Glyph="&#xEA6A;"/>
            </InfoBadge.IconSource>
        </InfoBadge>
    </Grid>
</Button>
```

Managing an InfoBadge

An InfoBadge typically displays a transient alert, so it's common to show or hide it, and change it's style periodically while your app is running.

Showing and hiding an InfoBadge

You can use either the Visibility property or Opacity property to show and hide an InfoBadge based on user actions, program logic, counters, etc.

As with other UIElements, setting `Visibility.Collapsed` will make the InfoBadge not take space in your layout, so it might cause other elements to move around when it's shown and hidden.

If elements being repositioned is a concern, you can use the `Opacity` property to show and hide the InfoBadge. `Opacity` is set to `1.0` by default; you can set it to `0` to hide the InfoBadge. When you use the `Opacity` property, InfoBadge will still take up space in the layout even if it is currently hidden.

Change the InfoBadge style

You can change the icon or number displayed in an InfoBadge while it is being shown. Decrementing or incrementing a numeric InfoBadge based on user action can be achieved by changing the value of `InfoBadge.Value`. Changing the icon of an InfoBadge can be achieved by setting `InfoBadge.IconSource` to a new `IconSource` object. When changing icons, ensure that the new icon is the same size as the old icon to avoid a jarring visual effect.

Default behavior

If neither `InfoBadge.Value` nor `InfoBadge.IconSource` are set, the InfoBadge defaults to showing a dot (specifically if `Value` is set to `-1` and `IconSource` is set to `null`, which are the default values). If both the `Value` and `IconSource` properties are set, the InfoBadge will honor the `Value` property and display a number value.

You can also change the InfoBadge's type while it is being shown. To change the type of InfoBadge, be sure that the current type's corresponding property (`Value` or `IconSource`) is set to its default value (`-1` or `null`), and set the new type's property equal to an appropriate value. To change the type of InfoBadge from numeric or icon to a dot type InfoBadge, make sure that `InfoBadge.Value` is set to `-1` and `InfoBadge.IconSource` is set to `null`.

Depending on how you've positioned your InfoBadge, be aware that this may cause items to shift as the size and shape of the InfoBadge may change.

UWP and WinUI 2

> **ⓘ Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.

This section contains information you need to use the control in a UWP or WinUI 2 app.

The InfoBadge for UWP apps requires WinUI 2. For more info, including installation instructions, see WinUI 2. APIs for this control exist in the Microsoft.UI.Xaml.Controls namespace.

- ✓ **WinUI 2 Apis:** InfoBadge class, IconSource property, Value property
- ✓ Open the WinUI 2 Gallery app and see InfoBadge in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

To use the code in this article with WinUI 2, use an alias in XAML (we use `muxc`) to represent the Windows UI Library APIs that are included in your project. See Get Started with WinUI 2 for more info.

XAML

```
xmlns:muxc="using:Microsoft.UI.Xaml.Controls"

<muxc:InfoBadge/>
```

Text controls

Article • 06/09/2022

Text controls consist of text input boxes, password boxes, auto-suggest boxes, and text blocks. The XAML framework provides several controls for rendering, entering, and editing text, and a set of properties for formatting the text.

- The controls for displaying read-only text are TextBlock and RichTextBlock.
- The controls for text entry and editing are: TextBox, RichEditBox, AutoSuggestBox, and PasswordBox.

> **Important APIs**: TextBlock class, RichTextBlock class, TextBox class, RichEditBox class, AutoSuggestBox class, PasswordBox class

Is this the right control?

The text control you use depends on your scenario. Use this info to pick the right text control to use in your app.

Render read-only text

Use a **TextBlock** to display most read-only text in your app. You can use it to display single-line or multi-line text, inline hyperlinks, and text with formatting like bold, italic, or underlined.

TextBlock is typically easier to use and provides better text rendering performance than RichTextBlock, so it's preferred for most app UI text. You can easily access and use text from a TextBlock in your app by getting the value of the Text property.

It also provides many of the same formatting options for customizing how your text is rendered. Although you can put line breaks in the text, TextBlock is designed to display a single paragraph and doesn't support text indentation.

Use a **RichTextBlock** when you need support for multiple paragraphs, multi-column text or other complex text layouts, or inline UI elements like images. RichTextBlock provides several features for advanced text layout.

The content property of RichTextBlock is the Blocks property, which supports paragraph based text via the Paragraph element. It doesn't have a **Text** property that you can use to easily access the control's text content in your app.

Text input

Use a **TextBox** control to let a user enter and edit unformatted text, such as in a form. You can use the Text property to get and set the text in a TextBox.

You can make a TextBox read-only, but this should be a temporary, conditional state. If the text is never editable, consider using a TextBlock instead.

Use a **PasswordBox** control to collect a password or other private data, such as a Social Security number. A password box is a text input box that conceals the characters typed in it for the sake of privacy. A password box looks like a text input box, except that it renders bullets in place of the text that has been entered. The bullet character can be customized.

Use an **AutoSuggestBox** control to show the user a list of suggestions to choose from as they type. An auto-suggest box is a text entry box that triggers a list of basic search suggestions. Suggested terms can draw from a combination of popular search terms and historical user-entered terms.

You should also use an AutoSuggestBox control to implement a search box.

Use a **RichEditBox** to display and edit text files. You don't use a RichEditBox to get user input into your app the way you use other standard text input boxes. Rather, you use it to work with text files that are separate from your app. You typically save text entered into a RichEditBox to a .rtf file.

Is text input the best option?

There are many ways you can get user input in your app. These questions will help answer whether one of the standard text input boxes or another control is the best fit for getting user input.

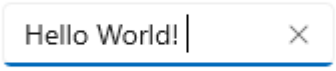
- **Is it practical to efficiently enumerate all valid values?** If so, consider using one of the selection controls, such as a check box, drop-down list, list box, radio button, slider, toggle switch, date picker, or time picker.
- **Is there a fairly small set of valid values?** If so, consider a drop-down list or a list box, especially if the values are more than a few characters long.
- **Is the valid data completely unconstrained? Or is the valid data only constrained by format (constrained length or character types)?** If so, use a text input control. You can limit the number of characters that can be entered, and you can validate the format in your app code.
- **Does the value represent a data type that has a specialized common control?** If so, use the appropriate control instead of a text input control. For example, use a DatePicker instead of a text input control to accept a date entry.

- If the data is strictly numeric:
  - **Is the value being entered approximate and/or relative to another quantity on the same page?** If so, use a slider.
  - **Would the user benefit from instant feedback on the effect of setting changes?** If so, use a slider, possibly with an accompanying control.
  - **Is the value entered likely to be adjusted after the result is observed, such as with volume or screen brightness?** If so, use a slider.

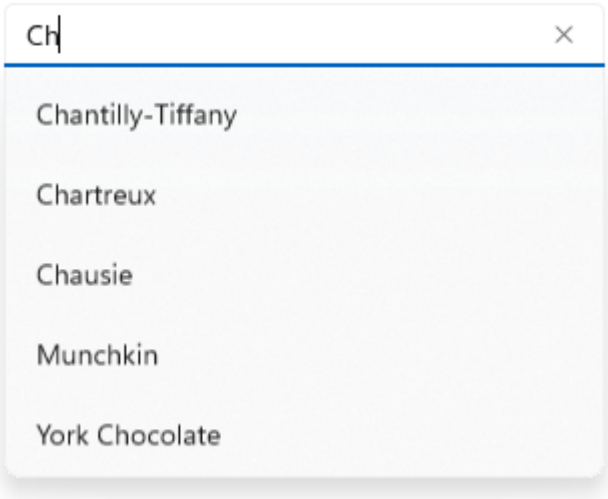
Examples

WinUI 2 Gallery
If you have the **WinUI 2 Gallery** app installed, click here to open the app and see the text controls in action. • Get the WinUI 2 Gallery app (Microsoft Store) • Get the source code (GitHub)

Text box



Auto suggest box



Password box

Create a text control

- PasswordBox
- RichEditBox
- RichTextBlock
- TextBlock
- TextBox

Font and style guidelines

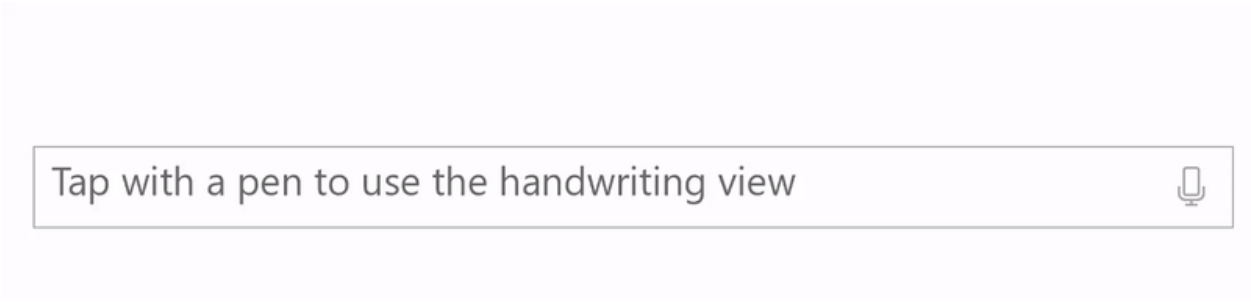
See these articles for font guidelines:

- Typography guidelines
- Segoe MDL2 icon list and guidelines

Pen input

Applies to: TextBox, RichEditBox, AutoSuggestBox

Starting with Windows 10, version 1803, XAML text input boxes feature embedded support for pen input using Windows Ink. When a user taps into a text input box using a Windows pen, the text box transforms to let the user write directly into it with a pen, rather than opening a separate input panel.



For more info, see Text input with the handwriting view.

Choose the right keyboard for your text control

Applies to: TextBox, PasswordBox RichEditBox

To help users to enter data using the touch keyboard, or Soft Input Panel (SIP), you can set the input scope of the text control to match the kind of data the user is expected to enter.

> Tip This info applies only to the SIP. It does not apply to hardware keyboards or the On-Screen Keyboard available in the Windows Ease of Access options.

The touch keyboard can be used for text entry when your app runs on a device with a touch screen. The touch keyboard is invoked when the user taps on an editable input field, such as a TextBox or RichEditBox. You can make it much faster and easier for users to enter data in your app by setting the input scope of the text control to match the kind of data you expect the user to enter. The input scope provides a hint to the system about the type of text input expected by the control so the system can provide a specialized touch keyboard layout for the input type.

For example, if a text box is used only to enter a 4-digit PIN, set the InputScope property to **Number**. This tells the system to show the number keypad layout, which makes it easier for the user to enter the PIN.

> Important
> The input scope does not cause any input validation to be performed, and does not prevent the user from providing any input through a hardware keyboard or other input device. You are still responsible for validating the input in your code as needed.

For more info, see Use input scope to change the touch keyboard.

Color fonts

Applies to: TextBlock, RichTextBlock, TextBox, RichEditBox

Windows has the ability for fonts to include multiple colored layers for each glyph. For example, the Segoe UI Emoji font defines color versions of the Emoticon and other Emoji characters.

The standard and rich text controls support display color fonts. By default, the **IsColorFontEnabled** property is **true** and fonts with these additional layers are rendered in color. The default color font on the system is Segoe UI Emoji and the controls will fall back to this font to display the glyphs in color.

XAML

```
<TextBlock FontSize="30">Hello ☺⛄☂♨⛅</TextBlock>
```

The rendered text looks like this:

For more info, see the IsColorFontEnabled property.

Guidelines for line and paragraph separators

Applies to: TextBlock, RichTextBlock, multi-line TextBox, RichEditBox

Use the line separator character (0x2028) and the paragraph separator character (0x2029) to divide plain text. A new line is begun after each line separator. A new paragraph is begun after each paragraph separator.

It isn't necessary to start the first line or paragraph in a file with these characters or to end the last line or paragraph with them; doing so indicates that there is an empty line

or paragraph in that location.

Your app can use the line separator to indicate an unconditional end of line. However, line separators do not correspond to the separate carriage return and linefeed characters, or to a combination of these characters. Line separators must be processed separately from carriage return and linefeed characters.

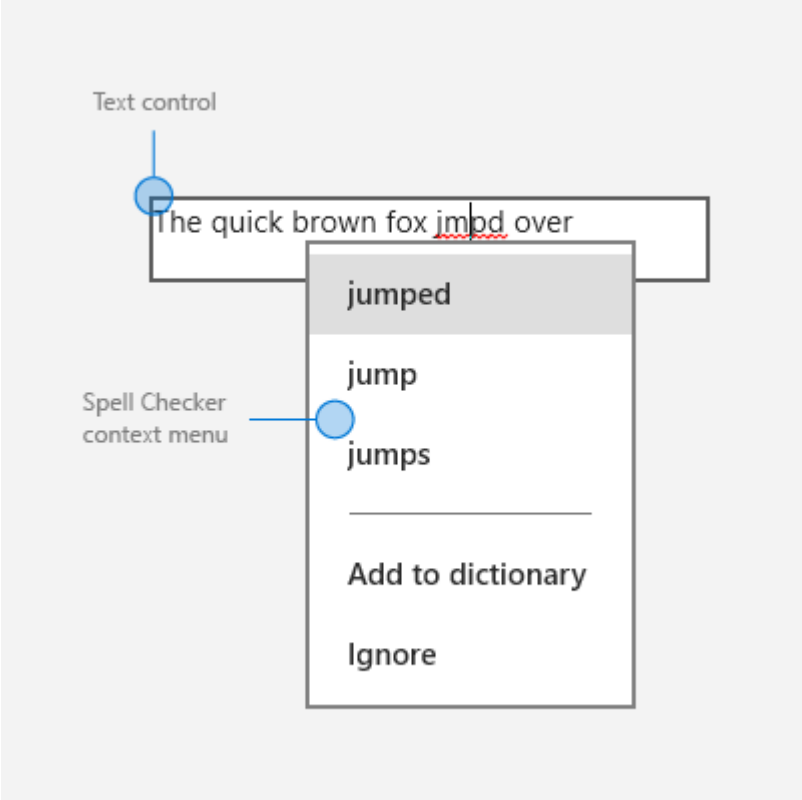
Your app can insert a paragraph separator between paragraphs of text. Use of this separator allows creation of plain text files that can be formatted with different line widths on different operating systems. The target system can ignore any line separators and break paragraphs only at the paragraph separators.

Guidelines for spell checking

Applies to: TextBox, RichEditBox

During text entry and editing, spell checking informs the user that a word is misspelled by highlighting it with a red squiggle and provides a way for the user to correct the misspelling.

Here's an example of the built-in spell checker:



Use spell checking with text input controls for these two purposes:

- **To auto-correct misspellings**

The spell checking engine automatically corrects misspelled words when it's confident about the correction. For example, the engine automatically changes "teh" to "the."

- **To show alternate spellings**

  When the spell checking engine is not confident about the corrections, it adds a red line under the misspelled word and displays the alternates in a context menu when you tap or right-click the word.

- Use spell checking to help users as they enter words or sentences into text input controls. Spell checking works with touch, mouse, and keyboard inputs.

- Don't use spell checking when a word is not likely to be in the dictionary or if users wouldn't value spell checking. For example, don't turn it on if the text box is intended to capture a telephone number or name.

- Don't disable spell checking just because the current spell checking engine doesn't support your app language. When the spell checker doesn't support a language, it doesn't do anything, so there's no harm in leaving the option on. Also, some users might use an Input Method Editor (IME) to enter another language into your app, and that language might be supported. For example, when building a Japanese language app, even though the spell checking engine might not currently recognize that language, don't turn spell checking off. The user may switch to an English IME and type English into the app; if spell checking is enabled, the English will get spell checked.

For TextBox and RichEditBox controls, spell checking is turned on by default. You can turn it off by setting the **IsSpellCheckEnabled** property to **false**.

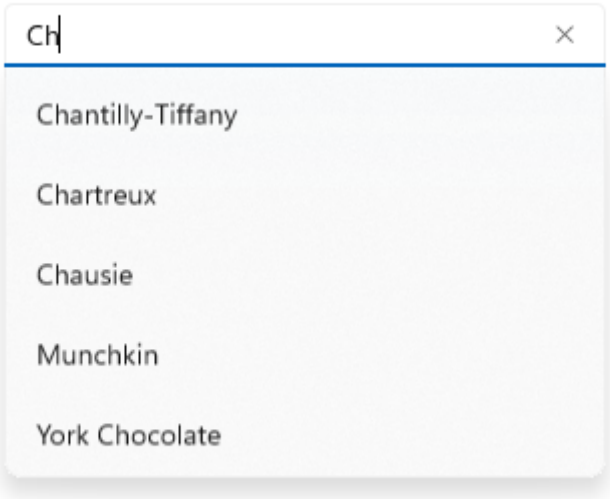
Auto-suggest box

Article • 02/26/2025

Use an AutoSuggestBox to provide a list of suggestions for a user to select from as they type.



Is this the right control?

If you'd like a simple, customizable control that allows text search with a list of suggestions, then choose an auto-suggest box.

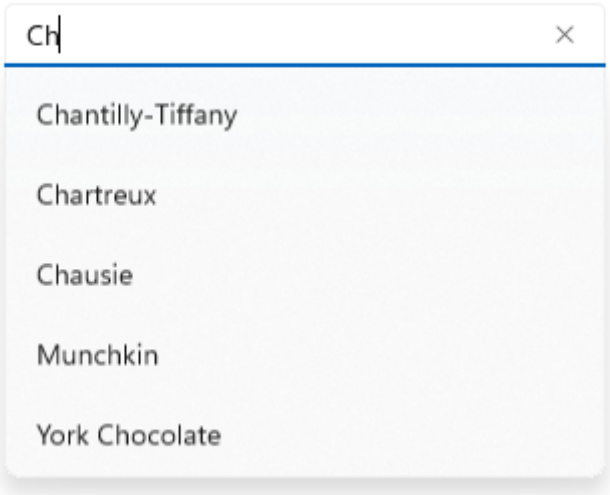
For more info about choosing the right text control, see the Text controls article.

Anatomy

The entry point for the auto-suggest box consists of an optional header and a text box with optional hint text:

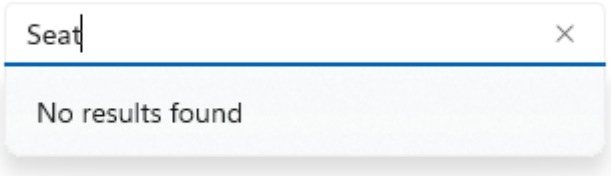
The auto-suggest results list populates automatically once the user starts to enter text. The results list can appear above or below the text entry box. A "clear all" button

appears:



Recommendations

- When using the auto-suggest box to perform searches and no search results exist for the entered text, display a single-line "No results" message as the result so that users know their search request executed:



Create an auto-suggest box

✓ **Important APIs:** AutoSuggestBox class, TextChanged event, SuggestionChose event, QuerySubmitted event

Open the WinUI 3 Gallery app and see the AutoSuggestBox in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

To use an AutoSuggestBox, you need to respond to 3 user actions.

- Text changed - When the user enters text, update the suggestion list.
- Suggestion chosen - When the user chooses a suggestion in the suggestion list, update the text box.
- Query submitted - When the user submits a query, show the query results.

Text changed

The TextChanged event occurs whenever the content of the text box is updated. Use the event args Reason property to determine whether the change was due to user input. If the change reason is **UserInput**, filter your data based on the input. Then, set the filtered data as the ItemsSource of the AutoSuggestBox to update the suggestion list.

To control how items are displayed in the suggestion list, you can use DisplayMemberPath or ItemTemplate.

- To display the text of a single property of your data item, set the DisplayMemberPath property to choose which property from your object to display in the suggestion list.
- To define a custom look for each item in the list, use the ItemTemplate property.

Suggestion chosen

When a user navigates through the suggestion list using the keyboard, you need to update the text in the text box to match.

You can set the TextMemberPath property to choose which property from your data object to display in the text box. If you specify a TextMemberPath, the text box is updated automatically. You should typically specify the same value for DisplayMemberPath and TextMemberPath so the text is the same in the suggestion list and the text box.

If you need to show more than a simple property, handle the SuggestionChosen event to populate the text box with custom text based on the selected item.

Query submitted

Handle the QuerySubmitted event to perform a query action appropriate to your app and show the result to the user.

The QuerySubmitted event occurs when a user commits a query string. The user can commit a query in one of these ways:

- While the focus is in the text box, press Enter or click the query icon. The event args ChosenSuggestion property is **null**.
- While the focus is in the suggestion list, press Enter, click, or tap an item. The event args ChosenSuggestion property contains the item that was selected from the list.

In all cases, the event args QueryText property contains the text from the text box.

Here is a simple AutoSuggestBox with the required event handlers.

XAML

```
<AutoSuggestBox PlaceholderText="Search" QueryIcon="Find" Width="200"
                TextChanged="AutoSuggestBox_TextChanged"
                QuerySubmitted="AutoSuggestBox_QuerySubmitted"
                SuggestionChosen="AutoSuggestBox_SuggestionChosen"/>
```

C#

```
private void AutoSuggestBox_TextChanged(AutoSuggestBox sender,
AutoSuggestBoxTextChangedEventArgs args)
{
    // Only get results when it was a user typing,
    // otherwise assume the value got filled in by TextMemberPath
    // or the handler for SuggestionChosen.
    if (args.Reason == AutoSuggestionBoxTextChangeReason.UserInput)
    {
        //Set the ItemsSource to be your filtered dataset
        //sender.ItemsSource = dataset;
    }
}

private void AutoSuggestBox_SuggestionChosen(AutoSuggestBox sender,
AutoSuggestBoxSuggestionChosenEventArgs args)
{
    // Set sender.Text. You can use args.SelectedItem to build your text
string.
}

private void AutoSuggestBox_QuerySubmitted(AutoSuggestBox sender,
AutoSuggestBoxQuerySubmittedEventArgs args)
{
    if (args.ChosenSuggestion != null)
    {
        // User selected an item from the suggestion list, take an action on
it here.
    }
    else
    {
        // Use args.QueryText to determine what to do.
```

```
    }
}
```

Use AutoSuggestBox for search

Use an AutoSuggestBox to provide a list of suggestions for a user to select from as they type.

By default, the text entry box doesn't have a query button shown. You can set the QueryIcon property to add a button with the specified icon on the right side of the text box. For example, to make the AutoSuggestBox look like a typical search box, add a 'find' icon, like this.

XAML

```
<AutoSuggestBox QueryIcon="Find"/>
```

Here's an AutoSuggestBox with a 'find' icon.

UWP and WinUI 2

> **ⓘ Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

APIs for this control exist in the Windows.UI.Xaml.Controls namespace.

- ✓ **UWP APIs:** AutoSuggestBox class, TextChanged event, SuggestionChose event, QuerySubmitted event

- ✓ Open the WinUI 2 Gallery app and see the AutoSuggestBox in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles and templates for all controls. WinUI 2.2 or later includes a new template for this control that uses rounded corners. For more info, see Corner radius.

Text block

Article • 02/05/2025

Text block is the primary control for displaying read-only text in apps. You can use it to display single-line or multi-line text, inline hyperlinks, and text with formatting like bold, italic, or underlined.

Is this the right control?

A text block is typically easier to use and provides better text rendering performance than a rich text block, so it's preferred for most app UI text. You can easily access and use text from a text block in your app by getting the value of the Text property. It also provides many of the same formatting options for customizing how your text is rendered.

Although you can put line breaks in the text, text block is designed to display a single paragraph and doesn't support text indentation. Use a **RichTextBlock** when you need support for multiple paragraphs, multi-column text or other complex text layouts, or inline UI elements like images.

For more info about choosing the right text control, see the Text controls article.

Create a text block

✓ **Important APIs:** TextBlock class, Text property, Inlines property

Open the WinUI 3 Gallery app and see the TextBlock in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

Here's how to define a simple TextBlock control and set its `Text` property to a string.

XAML

```
<TextBlock Text="Hello, world!" />
```

C#

```
TextBlock textBlock1 = new TextBlock();
textBlock1.Text = "Hello, world!";
```

Content model

There are two properties you can use to add content to a TextBlock: Text and Inlines.

The most common way to display text is to set the `Text` property to a string value, as shown in the previous example.

You can also add content by placing inline flow content elements in the `Inlines` property, like this. (`Inlines` is the default content property of a TextBlock, so you don't need to explicitly add it in XAML.)

XAML

```
<TextBlock>Text can be <Bold>bold</Bold>, <Underline>underlined</Underline>,
    <Italic>italic</Italic>, or a <Bold><Italic>combination</Italic></Bold>.
</TextBlock>
```

Elements derived from the Inline class, such as Bold, Italic, Run, Span, and LineBreak, enable different formatting for different parts of the text. For more info, see the Formatting text section. The inline Hyperlink element lets you add a hyperlink to your text. However, using `Inlines` also disables fast path text rendering, which is discussed in the next section.

Performance considerations

Whenever possible, XAML uses a more efficient code path to layout text. This fast path both decreases overall memory use and greatly reduces the CPU time to do text measuring and arranging. This fast path applies only to TextBlock, so it should be preferred when possible over RichTextBlock.

Certain conditions require TextBlock to fall back to a more feature-rich and CPU intensive code path for text rendering. To keep text rendering on the fast path, be sure to follow these guidelines when setting the properties listed here.

- Text: The most important condition is that the fast path is used only when you set text by explicitly setting the `Text` property, either in XAML or in code (as shown in the previous examples). Setting the text via TextBlock's `Inlines` collection (such as

`<TextBlock>Inline text</TextBlock>`) will disable the fast path, due to the potential complexity of multiple formats.

- CharacterSpacing: Only the default value of 0 is fast path.
- TextTrimming: Only the `None`, `CharacterEllipsis`, and `WordEllipsis` values are fast path. The `Clip` value disables the fast path.

> ⓘ Note
>
> **UWP Only:** Prior to Windows 10, version 1607, additional properties also affect the fast path. If your app is run on an earlier version of Windows, these conditions will cause your text to render on the slow path. For more info about versions, see Version adaptive code.
>
> - Typography: Only the default values for the various `Typography` properties are fast path.
> - LineStackingStrategy: If LineHeight is not 0, the `BaselineToBaseline` and `MaxHeight` values disable the fast path.
> - IsTextSelectionEnabled: Only `false` is fast path. Setting this property to `true` disables the fast path.

You can set the DebugSettings.IsTextPerformanceVisualizationEnabled property to `true` during debugging to determine whether text is using fast path rendering. When this property is set to `true`, the text that is on the fast path displays in a bright green color.

You typically set debug settings in the OnLaunched method override in the code-behind page for `App.xaml`, like this.

C#

```
protected override void OnLaunched(LaunchActivatedEventArgs e)
{
#if DEBUG
    if (System.Diagnostics.Debugger.IsAttached)
    {
        this.DebugSettings.IsTextPerformanceVisualizationEnabled = true;
    }
#endif

// ...

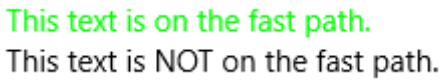
}
```

In this example, the first TextBlock is rendered using the fast path, while the second is not.

XAML

```
<StackPanel>
    <TextBlock Text="This text is on the fast path."/>
    <TextBlock>This text is NOT on the fast path.</TextBlock>
<StackPanel/>
```

When you run this XAML in debug mode with IsTextPerformanceVisualizationEnabled set to `true`, the result looks like this.



> **⊗ Caution**
>
> The color of text that is not on the fast path is not changed. If you have text in your app with its color specified as bright green, it is still displayed in bright green when it's on the slower rendering path. Be careful to not confuse text that is set to green in the app with text that is on the fast path and green because of the debug settings.

Formatting text

Although the Text property stores plain text, you can apply various formatting options to the TextBlock control to customize how the text is rendered in your app. You can set standard control properties like FontFamily, FontSize, FontStyle, Foreground, and CharacterSpacing to change the look of the text. You can also use inline text elements and Typography attached properties to format your text. These options affect only how the TextBlock displays the text locally, so if you copy and paste the text into a rich text control, for example, no formatting is applied.

> **ⓘ Note**
>
> Remember, as noted in the previous section, inline text elements and non-default typography values are not rendered on the fast path.

Inline elements

The Microsoft.UI.Xaml.Documents namespace provides a variety of inline text elements that you can use to format your text, such as Bold, Italic, Run, Span, and LineBreak.

You can display a series of strings in a TextBlock, where each string has different formatting. You can do this by using a `Run` element to display each string with its formatting and by separating each `Run` element with a `LineBreak` element.

Here's how to define several differently formatted text strings in a TextBlock by using `Run` objects separated with a `LineBreak`.

XAML

```
<TextBlock FontFamily="Segoe UI" Width="400" Text="Sample text formatting
runs">
    <LineBreak/>
    <Run Foreground="Gray" FontFamily="Segoe UI Light" FontSize="24">
        Segoe UI Light 24
    </Run>
    <LineBreak/>
    <Run Foreground="Teal" FontFamily="Georgia" FontSize="18"
FontStyle="Italic">
        Georgia Italic 18
    </Run>
    <LineBreak/>
    <Run Foreground="Black" FontFamily="Arial" FontSize="14"
FontWeight="Bold">
        Arial Bold 14
    </Run>
</TextBlock>
```

Here's the result.

Typography

The attached properties of the Typography class provide access to a set of Microsoft OpenType typography properties. You can set these attached properties either on the TextBlock, or on individual inline text elements. These examples show both.

XAML

```
<TextBlock Text="Hello, world!"
           Typography.Capitals="SmallCaps"
```

```
            Typography.StylisticSet4="True"/>
```

C#

```
TextBlock textBlock1 = new TextBlock();
textBlock1.Text = "Hello, world!";
Typography.SetCapitals(textBlock1, FontCapitals.SmallCaps);
Typography.SetStylisticSet4(textBlock1, true);
```

XAML

```
<TextBlock>12 x <Run Typography.Fraction="Slashed">1/3</Run> = 4.
</TextBlock>
```

UWP and WinUI 2

> **ⓘ Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

APIs for this control exist in the Windows.UI.Xaml.Controls namespace.

- ✓ **UWP APIs:** TextBlock class, Text property, Inlines property
- ✓ Open the WinUI 2 Gallery app and see the TextBlock in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

Rich text block

Article • 02/26/2025

Rich text blocks provide several features for advanced text layout that you can use when you need support for paragraphs, inline UI elements, or complex text layouts.

Is this the right control?

Use a **RichTextBlock** when you need support for multiple paragraphs, multi-column or other complex text layouts, or inline UI elements like images.

Use a **TextBlock** to display most read-only text in your app. You can use it to display single-line or multi-line text, inline hyperlinks, and text with formatting like bold, italic, or underlined. TextBlock provides a simpler content model, so it's typically easier to use, and it can provide better text rendering performance than RichTextBlock. It's preferred for most app UI text. Although you can put line breaks in the text, TextBlock is designed to display a single paragraph and doesn't support text indentation.

For more info about choosing the right text control, see the Text controls article.

Recommendations

See Typography and Guidelines for fonts.

Create a rich text block

✓ **Important APIs:** RichTextBlock class, RichTextBlockOverflow class, Paragraph class, Typography class

Open the WinUI 3 Gallery app and see the RichTextBlock in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

The content property of RichTextBlock is the Blocks property, which supports paragraph based text via the Paragraph element. It doesn't have a **Text** property that you can use to easily access the control's text content in your app. However, RichTextBlock provides several unique features that TextBlock doesn't provide.

RichTextBlock supports:

- Multiple paragraphs. Set the indentation for paragraphs by setting the TextIndent property.
- Inline UI elements. Use an InlineUIContainer to display UI elements, such as images, inline with your text.
- Overflow containers. Use RichTextBlockOverflow elements to create multi-column text layouts.

Paragraphs

You use Paragraph elements to define the blocks of text to display within a RichTextBlock control. Every RichTextBlock should include at least one Paragraph.

You can set the indent amount for all paragraphs in a RichTextBlock by setting the RichTextBlock.TextIndent property. You can override this setting for specific paragraphs in a RichTextBlock by setting the Paragraph.TextIndent property to a different value.

XAML

```
<RichTextBlock TextIndent="12">
  <Paragraph TextIndent="24">First paragraph.</Paragraph>
  <Paragraph>Second paragraph.</Paragraph>
  <Paragraph>Third paragraph. <Bold>With an inline.</Bold></Paragraph>
</RichTextBlock>
```

Inline UI elements

The InlineUIContainer class lets you embed any UIElement inline with your text. A common scenario is to place an Image inline with your text, but you can also use interactive elements, like a Button or CheckBox.

If you want to embed more than one element inline in the same position, consider using a panel as the single InlineUIContainer child, and then place the multiple elements within that panel.

This example shows how to use an InlineUIContainer to insert an image into a RichTextBlock.

XAML

```
<RichTextBlock>
    <Paragraph>
        <Italic>This is an inline image.</Italic>
```

```
        <InlineUIContainer>
            <Image Source="Assets/Square44x44Logo.png" Height="30"
Width="30"/>
        </InlineUIContainer>
        Mauris auctor tincidunt auctor.
    </Paragraph>
</RichTextBlock>
```

Overflow containers

You can use a RichTextBlock with RichTextBlockOverflow elements to create multi-column or other advanced page layouts. The content for a RichTextBlockOverflow element always comes from a RichTextBlock element. You link RichTextBlockOverflow elements by setting them as the OverflowContentTarget of a RichTextBlock or another RichTextBlockOverflow.

Here's a simple example that creates a two column layout. See the Examples section for a more complex example.

XAML

```
<Grid>
    <Grid.ColumnDefinitions>
        <ColumnDefinition/>
        <ColumnDefinition/>
    </Grid.ColumnDefinitions>
    <RichTextBlock Grid.Column="0"
                   OverflowContentTarget="{Binding
ElementName=overflowContainer}" >
        <Paragraph>
            Proin ac metus at quam luctus ultricies.
        </Paragraph>
    </RichTextBlock>
    <RichTextBlockOverflow x:Name="overflowContainer" Grid.Column="1"/>
</Grid>
```

Formatting text

Although the RichTextBlock stores plain text, you can apply various formatting options to customize how the text is rendered in your app. You can set standard control properties like FontFamily, FontSize, FontStyle, Foreground, and CharacterSpacing to change the look of the text. You can also use inline text elements and Typography attached properties to format your text. These options affect only how the RichTextBlock displays the text locally, so if you copy and paste the text into a rich text control, for example, no formatting is applied.

Inline elements

The Microsoft.UI.Xaml.Documents namespace provides a variety of inline text elements that you can use to format your text, such as Bold, Italic, Run, Span, and LineBreak. A typical way to apply formatting to sections of text is to place the text in a Run or Span element, and then set properties on that element.

Here's a Paragraph with the first phrase shown in bold, blue, 16pt text.

XAML

```
<Paragraph>
    <Bold><Span Foreground="DarkSlateBlue" FontSize="16">Lorem ipsum dolor
sit amet</Span></Bold>
    , consectetur adipiscing elit.
</Paragraph>
```

Typography

The attached properties of the Typography class provide access to a set of Microsoft OpenType typography properties. You can set these attached properties either on the RichTextBlock, or on individual inline text elements, as shown here.

XAML

```
<RichTextBlock Typography.StylisticSet4="True">
    <Paragraph>
        <Span Typography.Capitals="SmallCaps">Lorem ipsum dolor sit
amet</Span>
        , consectetur adipiscing elit.
    </Paragraph>
</RichTextBlock>
```

UWP and WinUI 2

ⓘ Important

The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.

This section contains information you need to use the control in a UWP or WinUI 2 app.

APIs for this control exist in the Windows.UI.Xaml.Controls namespace.

- ✓ **UWP APIs:** RichTextBlock class, RichTextBlockOverflow class, Paragraph class, Typography class
- ✓ Open the WinUI 2 Gallery app and see the RichTextBox in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles and templates for all controls. WinUI 2.2 or later includes a new template for this control that uses rounded corners. For more info, see Corner radius.

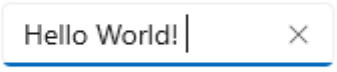
Text box

Article • 02/26/2025

The TextBox control lets a user type text into an app. It's typically used to capture a single line of text, but can be configured to capture multiple lines of text. The text displays on the screen in a simple, uniform, plaintext format.



TextBox has a number of features that can simplify text entry. It comes with a familiar, built-in context menu with support for copying and pasting text. The "clear all" button lets a user quickly delete all text that has been entered. It also has spell checking capabilities built in and enabled by default.

Is this the right control?

Use a **TextBox** control to let a user enter and edit unformatted text, such as in a form. You can use the Text property to get and set the text in a TextBox.

You can make a TextBox read-only, but this should be a temporary, conditional state. If the text is never editable, consider using a TextBlock instead.

Use a PasswordBox control to collect a password or other private data, such as a Social Security number. A password box looks like a text input box, except that it renders bullets in place of the text that has been entered.

Use an AutoSuggestBox control to let the user enter search terms or to show the user a list of suggestions to choose from as they type.

Use a RichEditBox to display and edit rich text files.

For more info about choosing the right text control, see the Text controls article.

Recommendations

- Use a label or placeholder text if the purpose of the text box isn't clear. A label is visible whether or not the text input box has a value. Placeholder text is displayed

inside the text input box and disappears once a value has been entered.
- Give the text box an appropriate width for the range of values that can be entered. Word length varies between languages, so take localization into account if you want your app to be world-ready.
- A text input box is typically single-line (`TextWrap = "NoWrap"`). When users need to enter or edit a long string, set the text input box to multi-line (`TextWrap = "Wrap"`).
- Generally, a text input box is used for editable text. But you can make a text input box read-only so that its content can be read, selected, and copied, but not edited.
- If you need to reduce clutter in a view, consider making a set of text input boxes appear only when a controlling checkbox is checked. You can also bind the enabled state of a text input box to a control such as a checkbox.
- Consider how you want a text input box to behave when it contains a value and the user taps it. The default behavior is appropriate for editing the value rather than replacing it; the insertion point is placed between words and nothing is selected. If replacing is the most common use case for a given text input box, you can select all the text in the field whenever the control receives focus, and typing replaces the selection.

Single-line input boxes

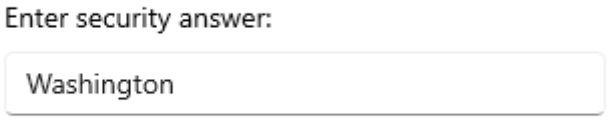
- Use several single-line text boxes to capture many small pieces of text information. If the text boxes are related in nature, group those together.

- Make the size of single-line text boxes slightly wider than the longest anticipated input. If doing so makes the control too wide, separate it into two controls. For example, you could split a single address input into "Address line 1" and "Address line 2".

- Set a maximum length for characters that can be entered. If the backing data source doesn't allow a long input string, limit the input and use a validation popup to let users know when they reach the limit.

- Use single-line text input controls to gather small pieces of text from users.

  The following example shows a single-line text box to capture an answer to a security question. The answer is expected to be short, and so a single-line text box is appropriate here.

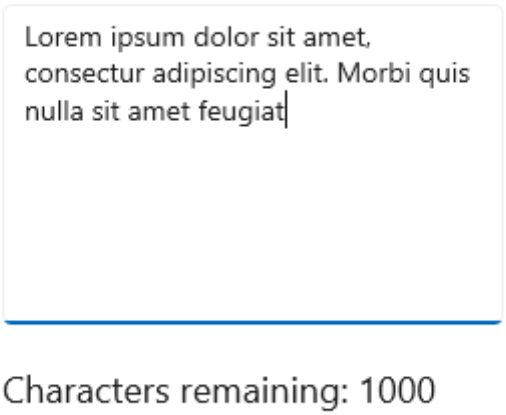


- Use a set of short, fixed-sized, single-line text input controls to enter data with a specific format.

- Use a single-line, unconstrained text input control to enter or edit strings, combined with a command button that helps users select valid values.

Multi-line text input controls

- When you create a rich text box, provide styling buttons and implement their actions.
- Use a font that's consistent with the style of your app.
- Make the height of the text control tall enough to accommodate typical entries.
- When capturing long spans of text with a maximum character or word count, use a plain text box and provide a live-running counter to show the user how many characters or words they have left before they reach the limit. You'll need to create the counter yourself; place it below the text box and dynamically update it as the user enters each character or word.



- Don't let your text input controls grow in height while users type.
- Don't use a multi-line text box when users only need a single line.
- Don't use a rich text control if a plain text control is adequate.

Create a text box

✔ **Important APIs:** TextBox class, Text property

Open the WinUI 3 Gallery app and see the TextBox in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

Here's the XAML for a simple text box with a header and placeholder text.

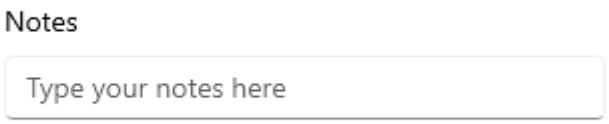
XAML

```
<TextBox Width="500" Header="Notes" PlaceholderText="Type your notes here"/>
```

C#

```
TextBox textBox = new TextBox();
textBox.Width = 300;
textBox.Header = "Notes";
textBox.PlaceholderText = "Type your notes here";
// Add the TextBox to the visual tree.
rootGrid.Children.Add(textBox);
```

Here's the text box that results from this XAML.



Use a text box for data input in a form

It's common to use a text box to accept data input on a form, and use the Text property to get the complete text string from the text box. You typically use an event like a submit button click to access the Text property, but you can handle the TextChanged or TextChanging event if you need to do something when the text changes.

This example shows how to get and set the current content of a text box.

XAML

```
<TextBox name="SampleTextBox" Text="Sample Text"/>
```

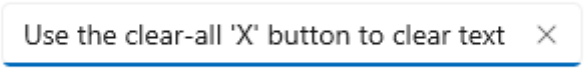
C#

```
string sampleText = SampleTextBox.Text;
...
SampleTextBox.Text = "Sample text retrieved";
```

You can add a Header (or label) and PlaceholderText (or watermark) to the text box to give the user an indication of what the text box is for. To customize the look of the header, you can set the HeaderTemplate property instead of Header. *For design info, see Guidelines for labels*.

You can restrict the number of characters the user can type by setting the MaxLength property. However, MaxLength does not restrict the length of pasted text. Use the Paste event to modify pasted text if this is important for your app.

The text box includes a clear all button ("X") that appears when text is entered in the box. When a user clicks the "X", the text in the text box is cleared. It looks like this.



The clear all button is shown only for editable, single-line text boxes that contain text and have focus.

The clear all button is not shown in any of these cases:

- **IsReadOnly** is **true**
- **AcceptsReturn** is **true**
- **TextWrap** has a value other than **NoWrap**

This example shows how to get and set the current content of a text box.

XAML

```
<TextBox name="SampleTextBox" Text="Sample Text"/>
```

C#

```
string sampleText = SampleTextBox.Text;
...
SampleTextBox.Text = "Sample text retrieved";
```

Make a text box read-only

You can make a text box read-only by setting the IsReadOnly property to **true**. You typically toggle this property in your app code based on conditions in your app. If need text that is always read-only, consider using a TextBlock instead.

You can make a TextBox read-only by setting the IsReadOnly property to true. For example, you might have a TextBox for a user to enter comments that is enabled only under certain conditions. You can make the TextBox read-only until the conditions are met. If you need only to display text, consider using a TextBlock or RichTextBlock instead.

A read-only text box looks the same as a read/write text box, so it might be confusing to a user. A user can select and copy text. IsEnabled

Enable multi-line input

There are two properties that you can use to control whether the text box displays text on more than one line. You typically set both properties to make a multi-line text box.

- To let the text box allow and display the newline or return characters, set the AcceptsReturn property to **true**.
- To enable text wrapping, set the TextWrapping property to **Wrap**. This causes the text to wrap when it reaches the edge of the text box, independent of line separator characters.

> **Note**
>
> TextBox and RichEditBox don't support the **WrapWholeWords** value for their TextWrapping properties. If you try to use WrapWholeWords as a value for TextBox.TextWrapping or RichEditBox.TextWrapping an invalid argument exception is thrown.

A multi-line text box will continue to grow vertically as text is entered unless it's constrained by its Height or MaxHeight property, or by a parent container. You should test that a multi-line text box doesn't grow beyond its visible area, and constrain its growth if it does. We recommend that you always specify an appropriate height for a multi-line text box, and not let it grow in height as the user types.

Scrolling using a scroll-wheel or touch is automatically enabled when needed. However, the vertical scrollbars are not visible by default. You can show the vertical scrollbars by setting the ScrollViewer.VerticalScrollBarVisibility to **Auto** on the embedded ScrollViewer, as shown here.

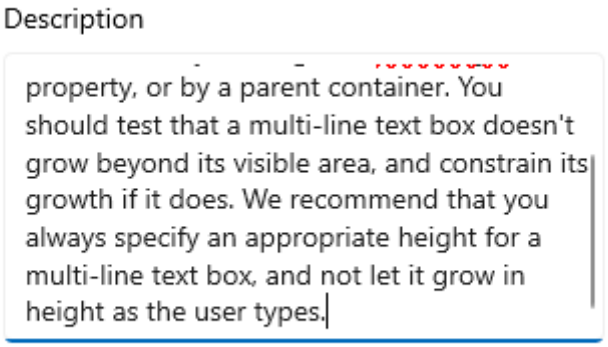
XAML

```
<TextBox AcceptsReturn="True" TextWrapping="Wrap"
         MaxHeight="172" Width="300" Header="Description"
         ScrollViewer.VerticalScrollBarVisibility="Auto"/>
```

C#

```
TextBox textBox = new TextBox();
textBox.AcceptsReturn = true;
textBox.TextWrapping = TextWrapping.Wrap;
textBox.MaxHeight = 172;
textBox.Width = 300;
textBox.Header = "Description";
ScrollViewer.SetVerticalScrollBarVisibility(textBox,
ScrollBarVisibility.Auto);
```

Here's what the text box looks like after text is added.



Format the text display

Use the TextAlignment property to align text within a text box. To align the text box within the layout of the page, use the HorizontalAlignment and VerticalAlignment properties.

While the text box supports only unformatted text, you can customize how the text is displayed in the text box to match your branding. You can set standard Control properties like FontFamily, FontSize, FontStyle, Background, Foreground, and CharacterSpacing to change the look of the text. These properties affect only how the text box displays the text locally, so if you were to copy and paste the text into a rich text control, for example, no formatting would be applied.

This example shows a read-only text box with several properties set to customize the appearance of the text.

XAML

```
<TextBox Text="Sample Text" IsReadOnly="True"
         FontFamily="Verdana" FontSize="24"
         FontWeight="Bold" FontStyle="Italic"
         CharacterSpacing="200" Width="300"
         Foreground="Blue" Background="Beige"/>
```

C#

```
TextBox textBox = new TextBox();
textBox.Text = "Sample Text";
textBox.IsReadOnly = true;
textBox.FontFamily = new FontFamily("Verdana");
textBox.FontSize = 24;
textBox.FontWeight = Windows.UI.Text.FontWeights.Bold;
```

```
textBox.FontStyle = Windows.UI.Text.FontStyle.Italic;
textBox.CharacterSpacing = 200;
textBox.Width = 300;
textBox.Background = new SolidColorBrush(Windows.UI.Colors.Beige);
textBox.Foreground = new SolidColorBrush(Windows.UI.Colors.Blue);
// Add the TextBox to the visual tree.
rootGrid.Children.Add(textBox);
```

The resulting text box looks like this.

Modify the context menu

By default, the commands shown in the text box context menu depend on the state of the text box. For example, the following commands can be shown when the text box is editable.

Expand table

Command	Shown when...
Copy	text is selected.
Cut	text is selected.
Paste	the clipboard contains text.
Select all	the TextBox contains text.
Undo	text has been changed.

To modify the commands shown in the context menu, handle the ContextMenuOpening event. For an example of this, see the **Customizing RichEditBox's CommandBarFlyout - adding 'Share'** example in the WinUI 2 Gallery. For design info, see Guidelines for context menus.

Select, copy, and paste

You can get or set the selected text in a text box using the SelectedText property. Use the SelectionStart and SelectionLength properties, and the Select and SelectAll methods,

to manipulate the text selection. Handle the SelectionChanged event to do something when the user selects or de-selects text. You can change the color used to highlight the selected text by setting the SelectionHighlightColor property.

TextBox supports copy and paste by default. You can provide custom handling of the Paste event on editable text controls in your app. For example, you might remove the line breaks from a multi-line address when pasting it into a single-line search box. Or, you might check the length of the pasted text and warn the user if it exceeds the maximum length that can be saved to a database. For more info and examples, see the Paste event.

Here, we have an example of these properties and methods in use. When you select text in the first text box, the selected text is displayed in the second text box, which is read-only. The values of the SelectionLength and SelectionStart properties are shown in two text blocks. This is done using the SelectionChanged event.

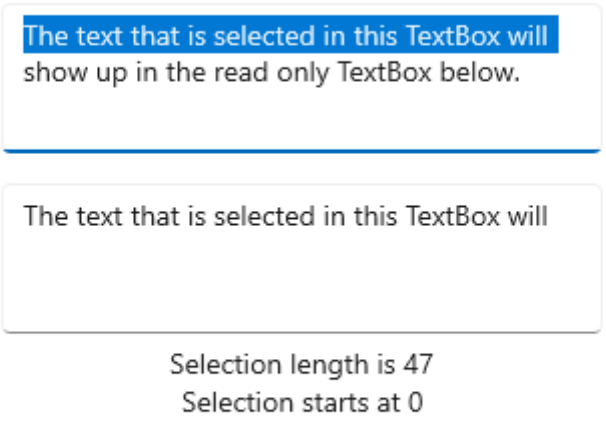
XAML

```
<StackPanel>
   <TextBox x:Name="textBox1" Height="75" Width="300" Margin="10"
         Text="The text that is selected in this TextBox will show up in the
read only TextBox below."
         TextWrapping="Wrap" AcceptsReturn="True"
         SelectionChanged="TextBox1_SelectionChanged" />
   <TextBox x:Name="textBox2" Height="75" Width="300" Margin="5"
         TextWrapping="Wrap" AcceptsReturn="True" IsReadOnly="True"/>
   <TextBlock x:Name="label1" HorizontalAlignment="Center"/>
   <TextBlock x:Name="label2" HorizontalAlignment="Center"/>
</StackPanel>
```

C#

```
private void TextBox1_SelectionChanged(object sender, RoutedEventArgs e)
{
    textBox2.Text = textBox1.SelectedText;
    label1.Text = "Selection length is " +
textBox1.SelectionLength.ToString();
    label2.Text = "Selection starts at " +
textBox1.SelectionStart.ToString();
}
```

Here's the result of this code.



Choose the right keyboard for your text control

To help users to enter data using the touch keyboard, or Soft Input Panel (SIP), you can set the input scope of the text control to match the kind of data the user is expected to enter.

The touch keyboard can be used for text entry when your app runs on a device with a touch screen. The touch keyboard is invoked when the user taps on an editable input field, such as a TextBox or RichEditBox. You can make it much faster and easier for users to enter data in your app by setting the input scope of the text control to match the kind of data you expect the user to enter. The input scope provides a hint to the system about the type of text input expected by the control so the system can provide a specialized touch keyboard layout for the input type.

For example, if a text box is used only to enter a 4-digit PIN, set the InputScope property to **Number**. This tells the system to show the number keypad layout, which makes it easier for the user to enter the PIN.

> **Important** The input scope does not cause any input validation to be performed, and does not prevent the user from providing any input through a hardware keyboard or other input device. You are still responsible for validating the input in your code as needed.

Other properties that affect the touch keyboard are IsSpellCheckEnabled, IsTextPredictionEnabled, and PreventKeyboardDisplayOnProgrammaticFocus. (IsSpellCheckEnabled also affects the TextBox when a hardware keyboard is used.)

For more info and examples, see Use input scope to change the touch keyboard and the property documentation.

UWP and WinUI 2

> **Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

APIs for this control exist in the Windows.UI.Xaml.Controls namespace.

- ✓ **UWP APIs:** TextBox class, Text property
- ✓ Open the WinUI 2 Gallery app and see the TextBox in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles and templates for all controls. WinUI 2.2 or later includes a new template for this control that uses rounded corners. For more info, see Corner radius.

Rich edit box

Article • 02/26/2025

You can use a RichEditBox control to enter and edit rich text documents that contain formatted text, hyperlinks, and images. You can make a RichEditBox read-only by setting its IsReadOnly property to **true**.

Is this the right control?

Use a **RichEditBox** to display and edit text files. You don't use a RichEditBox to get user input into you app the way you use other standard text input boxes. Rather, you use it to work with text files that are separate from your app. You typically save text entered into a RichEditBox to a .rtf file.

- If the primary purpose of the multi-line text box is for creating read-only documents (such as blog entries or the contents of an email message), and those documents require rich text, use a rich text block instead.
- When capturing text that will only be consumed and not redisplayed to users, use a plain text input control.
- For all other scenarios, use a plain text input control.

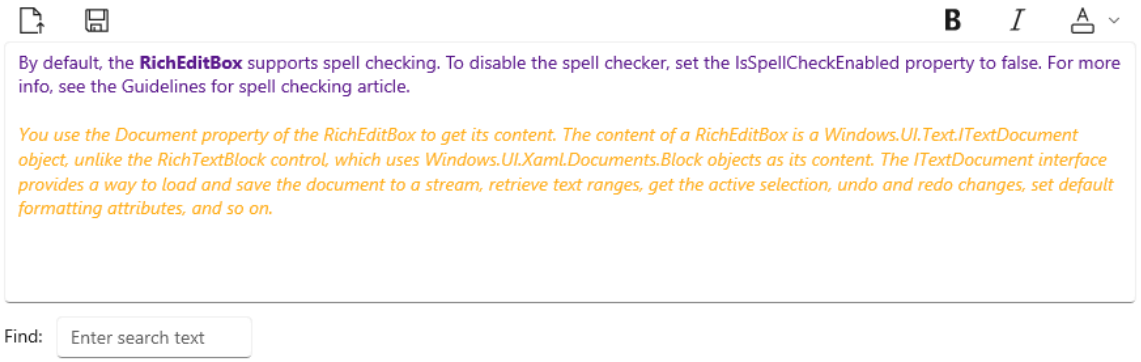
For more info about choosing the right text control, see the Text controls article.

Recommendations

- When you create a rich text box, provide styling buttons and implement their actions.
- Use a font that's consistent with the style of your app.
- Make the height of the text control tall enough to accommodate typical entries.
- Don't let your text input controls grow in height while users type.
- Don't use a multi-line text box when users only need a single line.
- Don't use a rich text control if a plain text control is adequate.

Examples

This rich edit box has a rich text document open in it. The formatting and file buttons aren't part of the rich edit box, but you should provide at least a minimal set of styling buttons and implement their actions.



Create a rich edit box

✔ **Important APIs:** RichEditBox class, Document property, IsReadOnly property, IsSpellCheckEnabled property

Open the WinUI 3 Gallery app and see the RichEditBox in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

By default, the RichEditBox supports spell checking. To disable the spell checker, set the IsSpellCheckEnabled property to **false**. For more info, see the Guidelines for spell checking article.

You use the Document property of the RichEditBox to get its content. The content of a RichEditBox is an ITextDocument object, unlike the RichTextBlock control, which uses Block objects as its content. The ITextDocument interface provides a way to load and save the document to a stream, retrieve text ranges, get the active selection, undo and redo changes, set default formatting attributes, and so on.

This example shows how to edit, load, and save a Rich Text Format (.rtf) file in a RichEditBox.

XAML

```
<RelativePanel Margin="20" HorizontalAlignment="Stretch">
    <RelativePanel.Resources>
        <Style TargetType="AppBarButton">
            <Setter Property="IsCompact" Value="True"/>
        </Style>
    </RelativePanel.Resources>
    <AppBarButton x:Name="openFileButton" Icon="OpenFile"
```

```
                Click="OpenButton_Click" ToolTipService.ToolTip="Open
file"/>
    <AppBarButton Icon="Save" Click="SaveButton_Click"
                  ToolTipService.ToolTip="Save file"
                  RelativePanel.RightOf="openFileButton" Margin="8,0,0,0"/>

    <AppBarButton Icon="Bold" Click="BoldButton_Click"
ToolTipService.ToolTip="Bold"
                  RelativePanel.LeftOf="italicButton" Margin="0,0,8,0"/>

        await file.OpenAsync(Windows.Storage.FileAccessMode.Read);

            // Load the file into the Document property of the RichEditBox.

editor.Document.LoadFromStream(Windows.UI.Text.TextSetOptions.FormatRtf,
randAccStream);
        }
        catch (Exception)
        {
            ContentDialog errorDialog = new ContentDialog()
            {
```

```
                Title = "File open error",
                Content = "Sorry, I couldn't open the file.",
                PrimaryButtonText = "Ok"
            };

            await errorDialog.ShowAsync();
        }
    }
}

private async void SaveButton_Click(object sender, RoutedEventArgs e)
{
    Windows.Storage.Pickers.FileSavePicker savePicker = new
Windows.Storage.Pickers.FileSavePicker();
    savePicker.SuggestedStartLocation =
Windows.Storage.Pickers.PickerLocationId.DocumentsLibrary;

    // Dropdown of file types the user can save the file as
    savePicker.FileTypeChoices.Add("Rich Text", new List<string>() { ".rtf"
});

    // Default file name if the user does not type one in or select a file
to replace
    savePicker.SuggestedFileName = "New Document";

    Windows.Storage.StorageFile file = await savePicker.PickSaveFileAsync();
    if (file != null)
    {
        // Prevent updates to the remote version of the file until we
        // finish making changes and call CompleteUpdatesAsync.
        Windows.Storage.CachedFileManager.DeferUpdates(file);
        // write to file
        Windows.Storage.Streams.IRandomAccessStream randAccStream =
            await file.OpenAsync(Windows.Storage.FileAccessMode.ReadWrite);

editor.Document.SaveToStream(Windows.UI.Text.TextGetOptions.FormatRtf,
randAccStream);

        // Let Windows know that we're finished changing the file so the
        // other app can update the remote version of the file.
        Windows.Storage.Provider.FileUpdateStatus status = await
Windows.Storage.CachedFileManager.CompleteUpdatesAsync(file);
        if (status != Windows.Storage.Provider.FileUpdateStatus.Complete)
        {
            Windows.UI.Popups.MessageDialog errorBox =
                new Windows.UI.Popups.MessageDialog("File " + file.Name + "
couldn't be saved.");
            await errorBox.ShowAsync();
        }
    }
}

private void BoldButton_Click(object sender, RoutedEventArgs e)
{
```

```
    Windows.UI.Text.ITextSelection selectedText = editor.Document.Selection;
    if (selectedText != null)
    {
        Windows.UI.Text.ITextCharacterFormat charFormatting =
selectedText.CharacterFormat;
        charFormatting.Bold = Windows.UI.Text.FormatEffect.Toggle;
        selectedText.CharacterFormat = charFormatting;
    }
}

private void ItalicButton_Click(object sender, RoutedEventArgs e)
{
    Windows.UI.Text.ITextSelection selectedText = editor.Document.Selection;
    if (selectedText != null)
    {
        Windows.UI.Text.ITextCharacterFormat charFormatting =
selectedText.CharacterFormat;
        charFormatting.Italic = Windows.UI.Text.FormatEffect.Toggle;
        selectedText.CharacterFormat = charFormatting;
    }
}

private void UnderlineButton_Click(object sender, RoutedEventArgs e)
{
    Windows.UI.Text.ITextSelection selectedText = editor.Document.Selection;
    if (selectedText != null)
    {
        Windows.UI.Text.ITextCharacterFormat charFormatting =
selectedText.CharacterFormat;
        if (charFormatting.Underline == Windows.UI.Text.UnderlineType.None)
        {
            charFormatting.Underline = Windows.UI.Text.UnderlineType.Single;
        }
        else {
            charFormatting.Underline = Windows.UI.Text.UnderlineType.None;
        }
        selectedText.CharacterFormat = charFormatting;
    }
}
```

Choose the right keyboard for your text control

To help users to enter data using the touch keyboard, or Soft Input Panel (SIP), you can set the input scope of the text control to match the kind of data the user is expected to enter. The default keyboard layout is usually appropriate for working with rich text documents.

For more info about how to use input scopes, see Use input scope to change the touch keyboard.

UWP and WinUI 2

Password box

Article • 02/26/2025

A password box is a text input box that conceals the characters typed into it for the purpose of privacy. A password box looks like a text box, except that it renders placeholder characters in place of the text that has been entered. You can configure the placeholder character.

By default, the password box provides a way for the user to view their password by holding down a reveal button. You can disable the reveal button, or provide an alternate mechanism to reveal the password, such as a check box.

Is this the right control?

Use a **PasswordBox** control to collect a password or other private data, such as a Social Security number.

For more info about choosing the right text control, see the Text controls article.

Recommendations

- Use a label or placeholder text if the purpose of the password box isn't clear. A label is visible whether or not the text input box has a value. Placeholder text is displayed inside the text input box and disappears once a value has been entered.
- Give the password box an appropriate width for the range of values that can be entered. Word length varies between languages, so take localization into account if you want your app to be world-ready.
- Don't put another control right next to a password input box. The password box has a password reveal button for users to verify the passwords they have typed, and having another control right next to it might make users accidentally reveal their passwords when they try to interact with the other control. To prevent this from happening, put some spacing between the password in put box and the other control, or put the other control on the next line.

- Consider presenting two password boxes for account creation: one for the new password, and a second to confirm the new password.
- Only show a single password box for logins.
- When a password box is used to enter a PIN, consider providing an instant response as soon as the last number is entered instead of using a confirmation button.

Examples

The password box has several states, including these notable ones.

A password box at rest can show hint text so that the user knows its purpose:

When the user types in a password box, the default behavior is to show bullets that hide the text being entered:

Pressing the "reveal" button on the right gives a peek at the password text being entered:

Create a password box

✓ **Important APIs:** PasswordBox class, Password property, PasswordChar property, PasswordRevealMode property, PasswordChanged event

Open the WinUI 3 Gallery app and see PasswordBox in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

Use the Password property to get or set the contents of the PasswordBox. You can do this in the handler for the PasswordChanged event to perform validation while the user enters the password. Or, you can use another event, like a button Click, to perform validation after the user completes the text entry.

Here's the XAML for a password box control that demonstrates the default look of the PasswordBox. When the user enters a password, you check to see if it's the literal value, "Password". If it is, you display a message to the user.

XAML

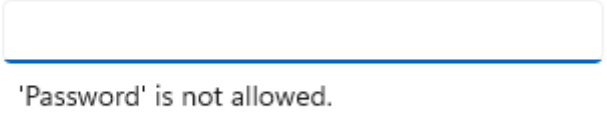
```
<StackPanel>
  <PasswordBox x:Name="passwordBox" Width="200" MaxLength="16"
               PasswordChanged="passwordBox_PasswordChanged"/>

  <TextBlock x:Name="statusText" Margin="10" HorizontalAlignment="Center" />
</StackPanel>
```

C#

```
private void passwordBox_PasswordChanged(object sender, RoutedEventArgs e)
{
    if (passwordBox.Password == "Password")
    {
        statusText.Text = "'Password' is not allowed as a password.";
    }
    else
    {
        statusText.Text = string.Empty;
    }
}
```

Here's the result when this code runs and the user enters "Password".



Password character

You can change the character used to mask the password by setting the PasswordChar property. Here, the default bullet is replaced with a pound sign.

XAML

```
<PasswordBox x:Name="passwordBox" Width="300" PasswordChar="#"/>
```

The result looks like this.

Headers and placeholder text

You can use the Header and PlaceholderText properties to provide context for the PasswordBox. This is especially useful when you have multiple boxes, such as on a form to change a password.

XAML

```
<PasswordBox x:Name="passwordBox" Width="200" Header="Password"
PlaceholderText="Enter your password"/>
```

Maximum length

Specify the maximum number of characters that the user can enter by setting the MaxLength property. There is no property to specify a minimum length, but you can check the password length, and perform any other validation, in your app code.

Password reveal mode

The PasswordBox has a built-in button that the user can press to display the password text. Here's the result of the user's action. When the user releases it, the password is automatically hidden again.

Peek mode

By default, the password reveal button (or "peek" button) is shown. The user must continuously press the button to view the password, so that a high level of security is maintained.

The value of the PasswordRevealMode property is not the only factor that determines whether a password reveal button is visible to the user. Other factors include whether the control is displayed above a minimum width, whether the PasswordBox has focus, and whether the text entry field contains at least one character. The password reveal button is shown only when the PasswordBox receives focus for the first time and a character is entered. If the PasswordBox loses focus and then regains focus, the reveal button is not shown again unless the password is cleared and character entry starts over.

Hidden and Visible modes

The other PasswordRevealMode enumeration values, **Hidden** and **Visible**, hide the password reveal button and let you programmatically manage whether the password is obscured.

To always obscure the password, set PasswordRevealMode to Hidden. Unless you need the password to be always obscured, you can provide a custom UI to let the user toggle the PasswordRevealMode between Hidden and Visible. For example, you can use a check box to toggle whether the password is obscured, as shown in the following example. You can also use other controls, like ToggleButton, to let the user switch modes.

This example shows how to use a CheckBox to let a user switch the reveal mode of a PasswordBox.

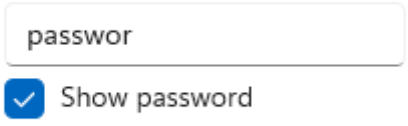
XAML

```
<StackPanel Width="200">
    <PasswordBox Name="passwordBox1"
                 PasswordRevealMode="Hidden"/>
    <CheckBox Name="revealModeCheckBox" Content="Show password"
              IsChecked="False"
              Checked="CheckBox_Changed" Unchecked="CheckBox_Changed"/>
</StackPanel>
```

C#

```
private void CheckBox_Changed(object sender, RoutedEventArgs e)
{
    if (revealModeCheckBox.IsChecked == true)
    {
        passwordBox1.PasswordRevealMode = PasswordRevealMode.Visible;
    }
    else
    {
        passwordBox1.PasswordRevealMode = PasswordRevealMode.Hidden;
    }
}
```

This PasswordBox looks like this.



Choose the right keyboard for your text control

To help users to enter data using the touch keyboard, or Soft Input Panel (SIP), you can set the input scope of the text control to match the kind of data the user is expected to enter. PasswordBox supports only the **Password** and **NumericPin** input scope values. Any other value is ignored.

For more info about how to use input scopes, see Use input scope to change the touch keyboard.

UWP and WinUI 2

> **Important**
>
> The information and examples in this article are optimized for apps that use the Windows App SDK and WinUI 3, but are generally applicable to UWP apps that use WinUI 2. See the UWP API reference for platform specific information and examples.
>
> This section contains information you need to use the control in a UWP or WinUI 2 app.

APIs for this control exist in the Windows.UI.Xaml.Controls namespace.

- ✓ **UWP APIs:** PasswordBox class, Password property, PasswordChar property, PasswordRevealMode property, PasswordChanged event
- ✓ Open the WinUI 2 Gallery app and see PasswordBox in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

We recommend using the latest WinUI 2 to get the most current styles and templates for all controls. WinUI 2.2 or later includes a new template for this control that uses rounded corners. For more info, see Corner radius.

Number box

Article • 02/26/2025

Represents a control that can be used to display and edit numbers. This supports validation, increment stepping, and computing inline calculations of basic equations, such as multiplication, division, addition, and subtraction.

Is this the right control?

You can use a NumberBox control to capture and display mathematic input. If you need an editable text box that accepts more than numbers, use the TextBox control. If you need an editable text box that accepts passwords or other sensitive input, see PasswordBox. If you need a text box to enter search terms, see AutoSuggestBox. If you need to enter or edit formatted text, see RichEditBox.

Recommendations

- `Text` and `Value` make it easy to capture the value of a NumberBox as a String or as a Double without needing to convert the value between types. When programmatically altering the value of a NumberBox, it is recommended to do so through the `Value` property. `Value` will overwrite `Text` in initial set up. After the initial set up, changes to one will be propagated to the other, but consistently making programmatic changes through `Value` helps avoid any conceptual misunderstanding that NumberBox will accept non-numeric characters through `Text`.
- Use `Header` or `PlaceholderText` to inform users that NumberBox accepts only numerical characters as input. Spelled representation of numbers, such as "one", will not resolve to an accepted value.

Create a NumberBox

✔ **Important APIs:** NumberBox class

Open the WinUI 3 Gallery app and see NumberBox in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

Here's the XAML for a basic NumberBox that demonstrates the default look. Use x:Bind to ensure the data displayed to the user remains in sync with the data stored in your app.

XAML

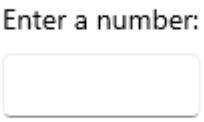
```
<NumberBox Value="{x:Bind Path=ViewModel.NumberBoxValue, Mode=TwoWay}" />
```

Labeling NumberBox

Use `Header` or `PlaceholderText` if the purpose of the NumberBox isn't clear. `Header` is visible whether or not the NumberBox has a value.

XAML

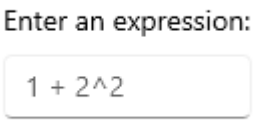
```
<NumberBox Header="Enter a number:"
    Value="{x:Bind Path=ViewModel.NumberBoxValue, Mode=TwoWay}" />
```



`PlaceholderText` is displayed inside the NumberBox and will only appear when `Value` is set to `NaN` or when the input is cleared by the user.

XAML

```
<NumberBox PlaceholderText="1+2^2"
    Value="{x:Bind Path=ViewModel.NumberBoxValue, Mode=TwoWay}" />
```



Enable calculation support

Setting the `AcceptsExpression` property to true enables NumberBox to evaluate basic inline expressions such as multiplication, division, addition, and subtraction using standard order of operations. Evaluation is triggered on loss of focus or when the user presses the "Enter" key. Once an expression is evaluated, the original form of the expression is not preserved.

XAML

```
<NumberBox Value="{x:Bind Path=ViewModel.NumberBoxValue, Mode=TwoWay}"
    AcceptsExpression="True" />
```

Increment and decrement stepping

Use the `SmallChange` property to configure how much the value inside a NumberBox is changed when the NumberBox is in focus and the user:

- scrolls
- presses the up arrow key
- presses the down arrow key

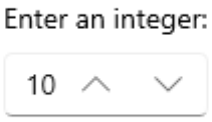
Use the `LargeChange` property to configure how much the value inside a NumberBox is changed when the NumberBox is in focus and the user press the PageUp or PageDown key.

Use the `SpinButtonPlacementMode` property to enable buttons that can be clicked to increment or decrement the value in the NumberBox by the amount specified by the `SmallChange` property. These buttons will be disabled if a Maximum or Minimum value would be surpassed with another step.

Set `SpinButtonPlacementMode` to `Inline` to enable the buttons to appear beside the control.

XAML

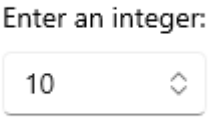
```
<NumberBox Value="{x:Bind Path=ViewModel.NumberBoxValue, Mode=TwoWay}"
    SmallChange="10"
    LargeChange="100"
    SpinButtonPlacementMode="Inline" />
```

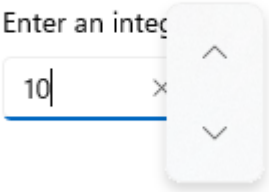


Set `SpinButtonPlacementMode` to `Compact` to enable the buttons to appear as a Flyout only when the NumberBox is in focus.

XAML

```
<NumberBox Value="{x:Bind Path=ViewModel.NumberBoxValue, Mode=TwoWay}"
    SmallChange="10"
    LargeChange="100"
    SpinButtonPlacementMode="Compact" />
```





Enabling input validation

Setting `ValidationMode` to `InvalidInputOverwritten` will enable NumberBox to overwrite invalid input that is not numerical nor legally formulaic with the last valid value when evaluation is triggered on loss of focus or a press of the "Enter" key.

XAML

```
<NumberBox Header="Quantity"
    Value="{x:Bind Path=ViewModel.NumberBoxValue, Mode=TwoWay}"
    ValidationMode="InvalidInputOverwritten" />
```

Setting `ValidationMode` to `Disabled` allows custom input validation to be configured.

With regard to decimal points and commas, the formatting used by a user will be replaced by the formatting configured for the NumberBox. An input validation error will not be triggered.

Formatting input

Number formatting can be used to format the value of a NumberBox by configuring an instance of a formatting class and assigning it to the `NumberFormatter` property. Decimal, currency, percent, and significant figures are few of the number formatting classes available. Note that rounding is also defined by number formatting properties.

Here is an example of using DecimalFormatter to format a NumberBox's value to have one integer digit, two fraction digits, and round up to the nearest 0.25:

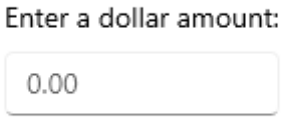
XAML

```
<NumberBox  x:Name="FormattedNumberBox"
    Value="{x:Bind Path=ViewModel.NumberBoxValue, Mode=TwoWay}" />
```

C#

```
private void SetNumberBoxNumberFormatter()
{
    IncrementNumberRounder rounder = new IncrementNumberRounder();
    rounder.Increment = 0.25;
    rounder.RoundingAlgorithm = RoundingAlgorithm.RoundUp;

    DecimalFormatter formatter = new DecimalFormatter();
    formatter.IntegerDigits = 1;
    formatter.FractionDigits = 2;
    formatter.NumberRounder = rounder;
    FormattedNumberBox.NumberFormatter = formatter;
}
```



With regard to decimal points and commas, the formatting used by a user will be replaced by the formatting configured for the NumberBox. An input validation error will not be triggered.

Remarks

Input Scope

`Number` will be used for the input scope. This input scope is intended for working with digits 0-9. This may be overwritten but alternative InputScope types will not be explicitly supported.

Not a Number

When a NumberBox is cleared of input, `Value` will be set to `NaN` to indicate no numerical value is present.

Expression evaluation

NumberBox uses infix notation to evaluate expressions. In order of precedence, the allowable operators are:

- ^
- */
- +-

Note that parentheses can be used to override precedence rules.

UWP and WinUI 2

> **ⓘ Important**

The information and examples in this article are optimized for apps that use the **Windows App SDK** and **WinUI 3**, but are generally applicable to UWP apps that use **WinUI 2**. See the UWP API reference for platform specific information and examples.

This section contains information you need to use the control in a UWP or WinUI 2 app.

The NumberBox for UWP apps requires WinUI 2. For more info, including installation instructions, see WinUI 2. APIs for this control exist in the Microsoft.UI.Xaml.Controls namespace.

- ✓ **WinUI 2 Apis:** NumberBox class
- ✓ Open the WinUI 2 Gallery app and see NumberBox in action. The **WinUI 2 Gallery** app includes interactive examples of most WinUI 2 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub.

To use the code in this article with WinUI 2, use an alias in XAML (we use `muxc`) to represent the Windows UI Library APIs that are included in your project. See Get Started with WinUI 2 for more info.

XAML

```
xmlns:muxc="using:Microsoft.UI.Xaml.Controls"

<muxc:NumberBox />
```

Labels

Article • 06/09/2022

A label is the name or title of a control or a group of related controls.

> **Important APIs**: Header property, TextBlock class

In XAML, many controls have a built-in Header property that you use to display the label. For controls that don't have a Header property, or to label groups of controls, you can use a TextBlock instead.

Recommendations

- Use a label to indicate to the user what they should enter into an adjacent control. You can also label a group of related controls, or display instructional text near a group of related controls.
- When labeling controls, write the label as a noun or a concise noun phrase, not as a sentence, and not as instructional text. Avoid colons or other punctuation.
- When you do have instructional text in a label, you can be more generous with text-string length and also use punctuation.

Content links in text controls

Article • 05/03/2022

Content links provide a way to embed rich data in your text controls, which lets a user find and use more information about a person or place without leaving the context of your app.

> **ⓘ Important**
>
> The Windows features that enable content links are not available in versions of Windows after Windows 10 version 1903. Content links for XAML text controls will not function in versions of Windows later than version 1903.

When the user prefixes an entry with the at (@) symbol in a RichEditBox, they're shown a list of people and/or place suggestions that matches the entry. Then, for example, when the user picks a place, a ContentLink for that place is inserted into the text. When the user invokes the content link from the RichEditBox, a flyout is shown with a map and additional info about the place.

> **Important APIs**: ContentLink class, ContentLinkInfo class, RichEditTextRange class

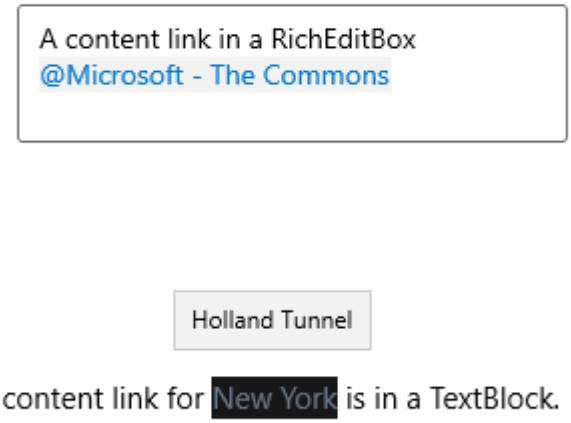
> **ⓘ Note**
>
> The APIs for content links are spread across the following namespaces: Windows.UI.Xaml.Controls, Windows.UI.Xaml.Documents, and Windows.UI.Text.

Content links in rich edit vs. text block controls

There are two distinct ways to use content links:

1. In a RichEditBox, the user can open a picker to add a content link by prefixing text with an @ symbol. The content link is stored as part the rich text content.
2. In a TextBlock or RichTextBlock, the content link is a text element with usage and behavior much like a Hyperlink.

Here's how content links look by default in a RichEditBox and in a TextBlock.



Differences in usage, rendering, and behavior are covered in detail in the following sections. This table gives a quick comparison of the main differences between a content link in a RichEditBox and a text block.

Expand table

Feature	RichEditBox	text block
Usage	ContentLinkInfo instance	ContentLink text element
Cursor	Determined by type of content link, can't be changed	Determined by Cursor property, **null** by default
ToolTip	Not rendered	Shows secondary text

Enable content links in a RichEditBox

The most common use of a content link is to let a user quickly add information by prefixing a person or place name with an ampersand (@) symbol in their text. When enabled in a RichEditBox, this opens a picker and lets the user insert a person from their contact list, or a nearby place, depending on what you've enabled.

The content link can be saved with the rich text content, and you can extract it to use in other parts of your app. For example, in an email app, you might extract the person info and use it to populate the To box with an email address.

> **Note**
>
> The content link picker is an app that's part of Windows, so it runs in a separate process from your app.

Content link providers

You enable content links in a RichEditBox by adding one or more content link providers to the RichEditBox.ContentLinkProviders collection. There are 2 content link providers built into the XAML framework.

- ContactContentLinkProvider – looks up contacts using the **People** app.
- PlaceContentLinkProvider – looks up places using the **Maps** app.

> ⓘ **Important**
>
> The default value for the RichEditBox.ContentLinkProviders property is **null**, not an empty collection. You need to explicitly create the **ContentLinkProviderCollection** before you add content link providers.

Here's how to add the content link providers in XAML.

XAML

```
<RichEditBox>
    <RichEditBox.ContentLinkProviders>
        <ContentLinkProviderCollection>
            <ContactContentLinkProvider/>
            <PlaceContentLinkProvider/>
        </ContentLinkProviderCollection>
    </RichEditBox.ContentLinkProviders>
</RichEditBox>
```

You can also add content link providers in a Style and apply it to multiple RichEditBoxes like this.

XAML

```
<Page.Resources>
    <Style TargetType="RichEditBox" x:Key="ContentLinkStyle">
        <Setter Property="ContentLinkProviders">
            <Setter.Value>
                <ContentLinkProviderCollection>
                    <PlaceContentLinkProvider/>
                    <ContactContentLinkProvider/>
                </ContentLinkProviderCollection>
            </Setter.Value>
        </Setter>
    </Style>
</Page.Resources>

<RichEditBox x:Name="RichEditBox01" Style="{StaticResource
```

```
ContentLinkStyle}" />
<RichEditBox x:Name="RichEditBox02" Style="{StaticResource
ContentLinkStyle}" />
```

Here's how to add content link providers in code.

```
C#

RichEditBox editor = new RichEditBox();
editor.ContentLinkProviders = new ContentLinkProviderCollection
{
    new ContactContentLinkProvider(),
    new PlaceContentLinkProvider()
};
```

Content link colors

The appearance of a content link is determined by its foreground, background, and icon. In a RichEditBox, you can set the ContentLinkForegroundColor and ContentLinkBackgroundColor properties to change the default colors.

You can't set the cursor. The cursor is rendered by the RichEditbox based on the type of content link - a Person cursor for a person link, or a Pin cursor for a place link.

The ContentLinkInfo object

When the user makes a selection from the people or places picker, the system creates a ContentLinkInfo object and adds it to the **ContentLinkInfo** property of the current RichEditTextRange.

The ContentLinkInfo object contains the information used to display, invoke, and manage the content link.

- **DisplayText** – This is the string that is shown when the content link is rendered. In a RichEditBox, the user can edit the text of a content link after it's created, which alters the value of this property.
- **SecondaryText** – This string is shown in the tooltip of a rendered content link.
  - In a Place content link created by the picker, it contains the address of the location, if available.
- **Uri** – The link to more information about the subject of the content link. This Uri can open an installed app or a website.
- **Id** - This is a read-only, per control, counter created by the RichEditBox control. It's used to track this ContentLinkInfo during actions such as delete or edit. If the

ContentLinkInfo is cut and paste back into the control, it will get a new Id. Id values are incremental.
- **LinkContentKind** – A string that describes the type of the content link. The built-in content types are *Places* and *Contacts*. The value is case sensitive.

Link content kind

There are several situations where the LinkContentKind is important.

- When a user copies a content link from a RichEditBox and pastes it into another RichEditBox, both controls must have a ContentLinkProvider for that content type. If not, the link is pasted as text.
- You can use LinkContentKind in a ContentLinkChanged event handler to determine what to do with a content link when you use it in other parts of your app. See the Example section for more info.
- The LinkContentKind influences how the system opens the Uri when the link is invoked. We'll see this in the discussion of Uri launching next.

Uri launching

The Uri property works much like the NavigateUri property of a Hyperlink. When a user clicks it, it launches the Uri in the default browser, or in the app that's registered for the particular protocol specified in the Uri value.

The specific behavior for the 2 built in kinds of link content are described here.

Places

The Places picker creates a ContentLinkInfo with a Uri root of https://maps.windows.com/. This link can be opened in 3 ways:

- If LinkContentKind = "Places", it opens an info card in a flyout. The flyout is similar to the content link picker flyout. It's part of Windows, and runs in a separate process from your app.
- If LinkContentKind is not "Places", it attempts to open the **Maps** app to the specified location. For example, this can happen if you've modified the LinkContentKind in the ContentLinkChanged event handler.
- If the Uri can't be opened in the Maps app, the map is opened in the default browser. This typically happens when the user's *Apps for websites* settings don't allow opening the Uri with the **Maps** app.

People

The People picker creates a ContentLinkInfo with a Uri that uses the **ms-people** protocol.

- If LinkContentKind = "People", it opens an info card in a flyout. The flyout is similar to the content link picker flyout. It's part of Windows, and runs in a separate process from your app.
- If LinkContentKind is not "People", it opens the **People** app. For example, this can happen if you've modified the LinkContentKind in the ContentLinkChanged event handler.

> **Tip**
>
> For more info about opening other apps and websites from your app, see the topics under **Launch an app with a Uri**.

Invoked

When the user invokes a content link, the ContentLinkInvoked event is raised before the default behavior of launching the Uri happens. You can handle this event to override or cancel the default behavior.

This example shows how you can override the default launching behavior for a Place content link. Instead of opening the map in a Place info card, Maps app, or default web browser, you mark the event as Handled and open the map in an in-app WebView control.

XAML

```
<RichEditBox x:Name="editor"
             ContentLinkInvoked="editor_ContentLinkInvoked">
    <RichEditBox.ContentLinkProviders>
        <ContentLinkProviderCollection>
            <PlaceContentLinkProvider/>
        </ContentLinkProviderCollection>
    </RichEditBox.ContentLinkProviders>
</RichEditBox>

<WebView x:Name="webView1"/>
```

C#

```
private void editor_ContentLinkInvoked(RichEditBox sender,
ContentLinkInvokedEventArgs args)
{
    if (args.ContentLinkInfo.LinkContentKind == "Places")
    {
        args.Handled = true;
        webView1.Navigate(args.ContentLinkInfo.Uri);
    }
}
```

ContentLinkChanged

You can use the ContentLinkChanged event to be notified when a content link is added, modified, or removed. This lets you extract the content link from the text and use it in other places in your app. This is shown later in the Examples section.

The properties of the ContentLinkChangedEventArgs are:

- **ChangedKind** - This ContentLinkChangeKind enum is the action within the ContentLink. For example, if the ContentLink is inserted, removed, or edited.
- **Info** - The ContentLinkInfo that was the target of the action.

This event is raised for each ContentLinkInfo action. For example, if the user copies and pastes several content links into the RichEditBox at once, this event is raised for each added item. Or if the user selects and deletes several content links at the same time, this event is raised for each deleted item.

This event is raised on the RichEditBox after the **TextChanging** event and before the **TextChanged** event.

Enumerate content links in a RichEditBox

You can use the RichEditTextRange.ContentLink property to get a content link from a rich edit document. The TextRangeUnit enumeration has the value ContentLink to specify the content link as a unit to use when navigating a text range.

This example shows how you can enumerate all the content links in a RichEditBox, and extract the people into a list.

XAML

```
<StackPanel Width="300">
    <RichEditBox x:Name="Editor" Height="200">
        <RichEditBox.ContentLinkProviders>
            <ContentLinkProviderCollection>
```

```
                <ContactContentLinkProvider/>
                <PlaceContentLinkProvider/>
            </ContentLinkProviderCollection>
        </RichEditBox.ContentLinkProviders>
    </RichEditBox>

    <Button Content="Get people" Click="Button_Click"/>

    <ListView x:Name="PeopleList" Header="People">
        <ListView.ItemTemplate>
            <DataTemplate x:DataType="ContentLinkInfo">
                <TextBlock>
                    <ContentLink Info="{x:Bind}" Background="Transparent"/>
                </TextBlock>
            </DataTemplate>
        </ListView.ItemTemplate>
    </ListView>
</StackPanel>
```

C#

```
private void Button_Click(object sender, RoutedEventArgs e)
{
    PeopleList.Items.Clear();
    RichEditTextRange textRange = Editor.Document.GetRange(0, 0) as
RichEditTextRange;

    do
    {
        // The Expand method expands the Range EndPosition
        // until it finds a ContentLink range.
        textRange.Expand(TextRangeUnit.ContentLink);
        if (textRange.ContentLinkInfo != null
            && textRange.ContentLinkInfo.LinkContentKind == "People")
        {
            PeopleList.Items.Add(textRange.ContentLinkInfo);
        }
    } while (textRange.MoveStart(TextRangeUnit.ContentLink, 1) > 0);
}
```

ContentLink text element

To use a content link in a TextBlock or RichTextBlock control, you use the ContentLink text element (from the Windows.UI.Xaml.Documents namespace).

Typical sources for a ContentLink in a text block are:

- A content link created by a picker that you extracted from a RichTextBlock control.
- A content link for a place that you create in your code.

For other situations, a Hyperlink text element is usually appropriate.

ContentLink appearance

The appearance of a content link is determined by its foreground, background, and cursor. In a text block, you can set the Foreground (from TextElement) and Background properties to change the default colors.

By default, the Hand cursor is shown when the user hovers over the content link. Unlike RichEditBlock, text block controls don't change the cursor automatically based on the link type. You can set the Cursor property to change the cursor based on link type or other factors.

Here's an example of a ContentLink used in a TextBlock. The ContentLinkInfo is created in code and assigned to the Info property of the ContentLink text element that's created in XAML.

XAML

```
<StackPanel>
    <TextBlock>
        <Span xml:space="preserve">
            <Run>This volcano erupted in 1980: </Run><ContentLink
x:Name="placeContentLink" Cursor="Pin"/>
            <LineBreak/>
        </Span>
    </TextBlock>

    <Button Content="Show" Click="Button_Click"/>
</StackPanel>
```

C#

```
private void Button_Click(object sender, RoutedEventArgs e)
{
    var info = new Windows.UI.Text.ContentLinkInfo();
    info.DisplayText = "Mount St. Helens";
    info.SecondaryText = "Washington State";
    info.LinkContentKind = "Places";
    info.Uri = new Uri("https://maps.windows.com?cp=46.1912~-122.1944");
    placeContentLink.Info = info;
}
```

Tip

When you use a ContentLink in a text control with other text elements in XAML, place the content in a **Span** container and apply the `xml:space="preserve"` attribute to the Span to keep the white space between the ContentLink and other elements.

Examples

In this example, a user can enter a person or place content link into a RickTextBlock. You handle the ContentLinkChanged event to extract the content links and keep them up-to-date in either a people list or places list.

In the item templates for the lists, you use a TextBlock with a ContentLink text element to show the content link info. The ListView provides its own background for each item, so the ContentLink background is set to Transparent.

XAML

```
<StackPanel Orientation="Horizontal" Grid.Row="1">
    <RichEditBox x:Name="Editor"
                 ContentLinkChanged="Editor_ContentLinkChanged"
                 Margin="20" Width="300" Height="200"
                 VerticalAlignment="Top">
        <RichEditBox.ContentLinkProviders>
            <ContentLinkProviderCollection>
                <ContactContentLinkProvider/>
                <PlaceContentLinkProvider/>
            </ContentLinkProviderCollection>
        </RichEditBox.ContentLinkProviders>
    </RichEditBox>

    <ListView x:Name="PeopleList" Header="People">
        <ListView.ItemTemplate>
            <DataTemplate x:DataType="ContentLinkInfo">
                <TextBlock>
                    <ContentLink Info="{x:Bind}"
                                 Background="Transparent"
                                 Cursor="Person"/>
                </TextBlock>
            </DataTemplate>
        </ListView.ItemTemplate>
    </ListView>

    <ListView x:Name="PlacesList" Header="Places">
        <ListView.ItemTemplate>
            <DataTemplate x:DataType="ContentLinkInfo">
                <TextBlock>
                    <ContentLink Info="{x:Bind}"
                                 Background="Transparent"
                                 Cursor="Pin"/>
                </TextBlock>
```

```
            </DataTemplate>
        </ListView.ItemTemplate>
    </ListView>
</StackPanel>
```

C#

```
private void Editor_ContentLinkChanged(RichEditBox sender,
ContentLinkChangedEventArgs args)
{
    var info = args.ContentLinkInfo;
    var change = args.ChangeKind;
    ListViewBase list = null;

    // Determine whether to update the people or places list.
    if (info.LinkContentKind == "People")
    {
        list = PeopleList;
    }
    else if (info.LinkContentKind == "Places")
    {
        list = PlacesList;
    }

    // Determine whether to add, delete, or edit.
    if (change == ContentLinkChangeKind.Inserted)
    {
        Add();
    }
    else if (args.ChangeKind == ContentLinkChangeKind.Removed)
    {
        Remove();
    }
    else if (change == ContentLinkChangeKind.Edited)
    {
        Remove();
        Add();
    }

    // Add content link info to the list. It's bound to the
    // Info property of a ContentLink in XAML.
    void Add()
    {
        list.Items.Add(info);
    }

    // Use ContentLinkInfo.Id to find the item,
    // then remove it from the list using its index.
    void Remove()
    {
        var items = list.Items.Where(i => ((ContentLinkInfo)i).Id ==
info.Id);
        var item = items.FirstOrDefault();
```

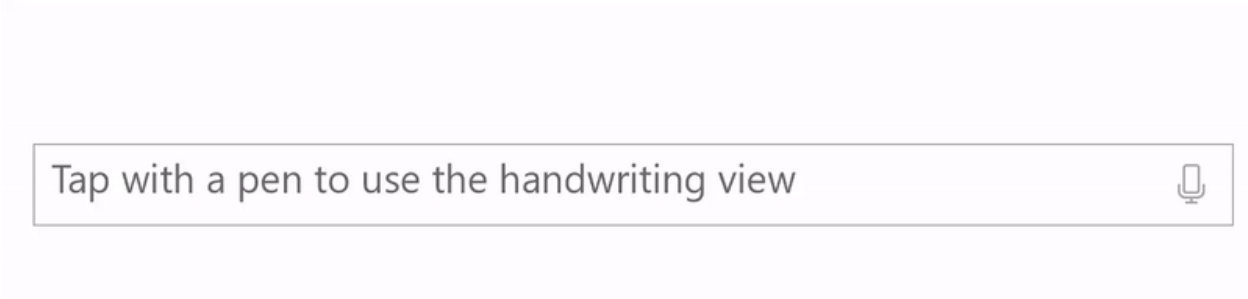
```
        var idx = list.Items.IndexOf(item);

        list.Items.RemoveAt(idx);
    }
}
```

Text input with the handwriting view

Article • 03/24/2023

> **Note**
>
> Handwriting view is not supported by text controls in the **Windows App SDK**. This article applies to UWP apps only.



Customize the handwriting view (for ink to text input) that is built into UWP text input controls such as the TextBox, RichEditBox, and AutoSuggestBox.

Overview

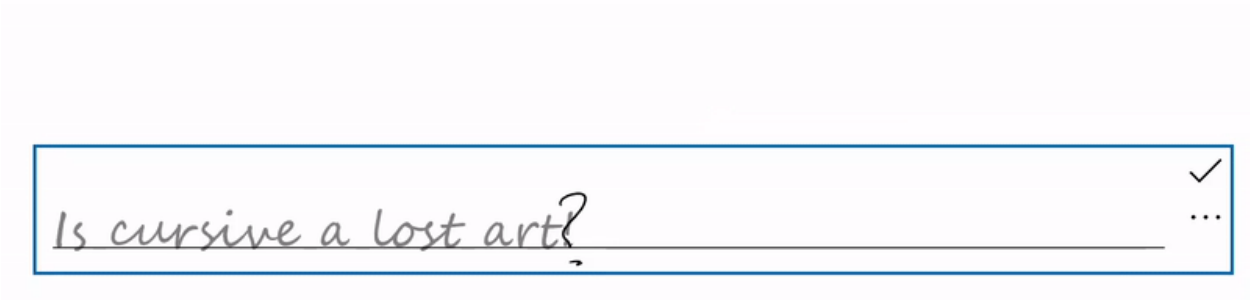
UWP text input controls support pen input using Windows Ink by transforming into a handwriting surface when a user taps into a text input box using a pen.

Text is recognized as the user writes anywhere in the handwriting surface while a candidate window shows the recognition results. The user can tap a result to choose it, or continue writing to accept the proposed candidate. The literal (letter-by-letter) recognition results are included in the candidate window, so recognition is not restricted to words in a dictionary. As the user writes, the accepted text input is converted to a script font that retains the feel of natural writing.

> **Note**
>
> The handwriting view is enabled by default, but you can disable it on a per-control basis and revert to the text input panel instead.

A user can edit their text using standard gestures and actions:

- *strike through* or *scratch out* - draw through to delete a word or part of a word
- *join* - draw an arc between words to delete the space between them
- *insert* - draw a caret symbol to insert a space
- *overwrite* - write over existing text to replace it



Disable the handwriting view

The built-in handwriting view is enabled by default.

You might want to disable the handwriting view if you already provide equivalent ink-to-text functionality in your application, or your text input experience relies on some kind of formatting or special character (such as a tab) not available through handwriting.

In this example, we disable the handwriting view by setting the IsHandwritingViewEnabled property of the TextBox control to false. All text controls that support the handwriting view support a similar property.

XAML

```
<TextBox Name="SampleTextBox"
    Height="50" Width="500"
    FontSize="36" FontFamily="Segoe UI"
    PlaceholderText="Try taping with your pen"
    IsHandwritingViewEnabled="False">
</TextBox>
```

Specify the alignment of the handwriting view

The handwriting view is located above the underlying text control and sized to accommodate the user's handwriting preferences (see **Settings -> Bluetooth & devices -> Pen & Windows Ink -> Handwriting -> Font size**). The view is also automatically aligned relative to the text control and its location within the app.

The application UI does not reflow to accommodate the larger control, which might occlude important UI.

The following snippet shows how to use the PlacementAlignment property of a TextBox HandwritingView to specify which anchor on the underlying text control is used to align the handwriting view.

XAML

```
<TextBox Name="SampleTextBox"
    Height="50" Width="500"
    FontSize="36" FontFamily="Segoe UI"
    PlaceholderText="Try taping with your pen">
        <TextBox.HandwritingView>
            <HandwritingView PlacementAlignment="TopLeft"/>
        </TextBox.HandwritingView>
</TextBox>
```

Disable auto-completion candidates

The text suggestion popup is enabled by default. It provides a list of top ink recognition candidates from which the user can select in case the primary candidate is incorrect.

If your application already provides robust, custom recognition functionality, you can use the AreCandidatesEnabled property to disable the built-in suggestions, as shown in the following example.

XAML

```
<TextBox Name="SampleTextBox"
    Height="50" Width="500"
    FontSize="36" FontFamily="Segoe UI"
    PlaceholderText="Try taping with your pen">
        <TextBox.HandwritingView>
            <HandwritingView AreCandidatesEnabled="False"/>
        </TextBox.HandwritingView>
</TextBox>
```

Use handwriting font preferences

A user can choose from a pre-defined collection of handwriting-based fonts to use when rendering text based on ink recognition (see **Settings -> Bluetooth & devices -> Pen & Windows Ink -> Handwriting -> Font**).

Your app can access this setting and use the selected font for the recognized text in the text control.

In this example, we listen for the TextChanged event of a TextBox and apply the user's selected font if the text change originated from the HandwritingView (or a default font, if not).

C#

```
private void SampleTextBox_TextChanged(object sender, TextChangedEventArgs
e)
{
    ((TextBox)sender).FontFamily =
        ((TextBox)sender).HandwritingView.IsOpen ?
            new FontFamily(PenAndInkSettings.GetDefault().FontFamilyName) :
            new FontFamily("Segoe UI");
}
```

Access the HandwritingView in composite controls

Composite controls that use either the TextBox or RichEditBox control (such as AutoSuggestBox), also support a HandwritingView.

To access the HandwritingView in a composite control, use the VisualTreeHelper API.

The following XAML snippet displays an AutoSuggestBox control.

XAML

```
<AutoSuggestBox Name="SampleAutoSuggestBox"
    Height="50" Width="500"
    PlaceholderText="Auto Suggest Example"
    FontSize="16" FontFamily="Segoe UI"
    Loaded="SampleAutoSuggestBox_Loaded">
</AutoSuggestBox>
```

In the corresponding code-behind, we show how to disable the HandwritingView on the AutoSuggestBox.

1. First, we handle the element's Loaded event and call a `FindInnerTextBox` function to start the visual tree traversal.

```
C#

private void SampleAutoSuggestBox_Loaded(object sender, RoutedEventArgs
e)
{
    if (FindInnerTextBox((AutoSuggestBox)sender))
        autoSuggestInnerTextBox.IsHandwritingViewEnabled = false;
}
```

2. In the `FindInnerTextBox` function, we iterate through the visual tree (starting at an AutoSuggestBox) by calling a `FindVisualChildByName` function.

```
csharp

private bool FindInnerTextBox(AutoSuggestBox autoSuggestBox)
{
    if (autoSuggestInnerTextBox == null)
    {
        // Cache textbox to avoid multiple tree traversals.
        autoSuggestInnerTextBox =
            (TextBox)FindVisualChildByName<TextBox>(autoSuggestBox);
    }
    return (autoSuggestInnerTextBox != null);
}
```

3. Finally, the `FindVisualChildByName` function iterates through the visual tree until the TextBox is retrieved.

```
C#

private FrameworkElement FindVisualChildByName<T>(DependencyObject obj)
{
    FrameworkElement element = null;
    int childrenCount =
        VisualTreeHelper.GetChildrenCount(obj);
    for (int i = 0; (i < childrenCount) && (element == null); i++)
    {
        FrameworkElement child =
            (FrameworkElement)VisualTreeHelper.GetChild(obj, i);
        if ((child.GetType()).Equals(typeof(T)) ||
(child.GetType().GetTypeInfo().IsSubclassOf(typeof(T))))
        {
            element = child;
        }
```

```
            else
            {
                element = FindVisualChildByName<T>(child);
            }
        }
        return (element);
    }
```

Reposition the HandwritingView

In some cases, you might need to ensure that the HandwritingView covers UI elements that it otherwise might not.

Here, we create a TextBox that supports dictation (implemented by placing a TextBox and a dictation button into a StackPanel).

As the StackPanel is now larger than the TextBox, the HandwritingView might not occlude all of the composite control.

To address this, set the PlacementTarget property of the HandwritingView to the UI element to which it should be aligned.

XAML

```
<StackPanel Name="DictationBox"
    Orientation="Horizontal"
    VerticalAlignment="Top"
    HorizontalAlignment="Left"
    BorderThickness="1" BorderBrush="DarkGray"
    Height="55" Width="500" Margin="50">
    <TextBox Name="DictationTextBox"
        Width="450" BorderThickness="0"
        FontSize="24" VerticalAlignment="Center">
        <TextBox.HandwritingView>
            <HandwritingView PlacementTarget="{Binding
ElementName=DictationBox}"/>
        </TextBox.HandwritingView>
    </TextBox>
```

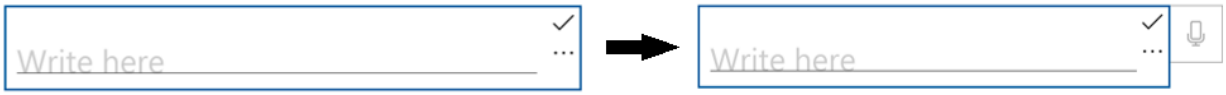
```
    <Button Name="DictationButton"
        Height="48" Width="48"
        FontSize="24"
        FontFamily="Segoe MDL2 Assets"
        Content="&#xE720;"
        Background="White" Foreground="DarkGray"
Tapped="DictationButton_Tapped" />
</StackPanel>
```

Resize the HandwritingView

You can also set the size of the HandwritingView, which can be useful when you need to ensure the view doesn't occlude important UI.

Like the previous example, we create a TextBox that supports dictation (implemented by placing a TextBox and a dictation button into a StackPanel).

In this case, we resize the HandwritingView to ensure that the dictation button is visible.



To do this, we bind the MaxWidth property of the HandwritingView to the width of the UI element that it should occlude.

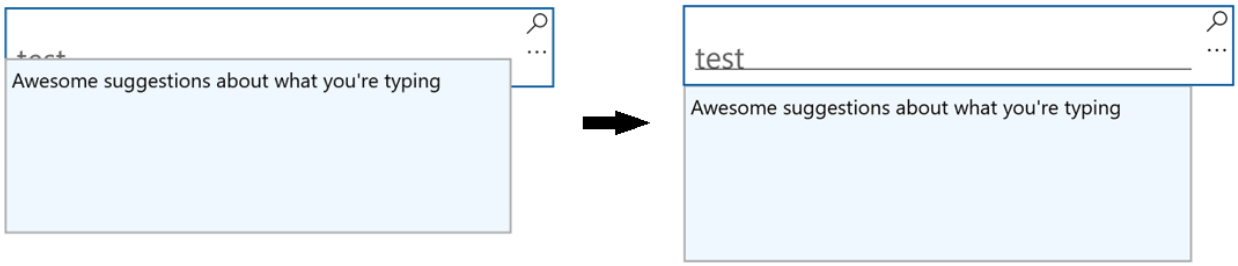
XAML

```
<StackPanel Name="DictationBox"
    Orientation="Horizontal"
    VerticalAlignment="Top"
    HorizontalAlignment="Left"
    BorderThickness="1"
    BorderBrush="DarkGray"
    Height="55" Width="500"
    Margin="50">
    <TextBox Name="DictationTextBox"
        Width="450"
        BorderThickness="0"
        FontSize="24"
        VerticalAlignment="Center">
        <TextBox.HandwritingView>
            <HandwritingView
                PlacementTarget="{Binding ElementName=DictationBox}"
```

```
                MaxWidth="{Binding ElementName=DictationTextBox,
Path=Width"/>
        </TextBox.HandwritingView>
    </TextBox>
    <Button Name="DictationButton"
        Height="48" Width="48"
        FontSize="24"
        FontFamily="Segoe MDL2 Assets"
        Content="&#xE720;"
        Background="White" Foreground="DarkGray"
        Tapped="DictationButton_Tapped" />
</StackPanel>
```

Reposition custom UI

If you have custom UI that appears in response to text input, such as an informational popup, you might need to reposition that UI so it doesn't occlude the handwriting view.



The following example shows how to listen for the Opened, Closed, and SizeChanged events of the HandwritingView to set the position of a Popup.

C#

```
private void Search_HandwritingViewOpened(
    HandwritingView sender, HandwritingPanelOpenedEventArgs args)
{
    UpdatePopupPositionForHandwritingView();
}

private void Search_HandwritingViewClosed(
    HandwritingView sender, HandwritingPanelClosedEventArgs args)
{
    UpdatePopupPositionForHandwritingView();
}

private void Search_HandwritingViewSizeChanged(
    object sender, SizeChangedEventArgs e)
{
    UpdatePopupPositionForHandwritingView();
}

private void UpdatePopupPositionForHandwritingView()
```

```
{
if (CustomSuggestionUI.IsOpen)
    CustomSuggestionUI.VerticalOffset = GetPopupVerticalOffset();
}

private double GetPopupVerticalOffset()
{
    if (SearchTextBox.HandwritingView.IsOpen)
        return (SearchTextBox.Margin.Top +
SearchTextBox.HandwritingView.ActualHeight);
    else
        return (SearchTextBox.Margin.Top + SearchTextBox.ActualHeight);
}
```

Re-template the HandwritingView control

As with all XAML framework controls, you can customize both the visual structure and visual behavior of a HandwritingView for your specific requirements.

To see a full example of creating a custom template check out the Create custom transport controls how-to or the Custom Edit Control sample.

Title bar

Article • 03/31/2025

The TitleBar control provides a simplified way to create a custom title bar for your app. The title bar is a fundamental component of a Windows app's user interface that identifies the app via its icon and title, houses the system caption buttons that let a user close, maximize, minimize, and restore the window, and lets a user drag the window around the screen.

You can use a custom title bar to better integrate the title bar area with your app UI. The title bar can be customized to match the app's visual style using Mica theming. It can include other relevant information, such as a document title or the current state (e.g., “Editing,” “Viewing,” etc.). It can also host other WinUI controls, like AutoSuggestBox and PersonPicture, providing a cohesive user experience for your app.

Is this the right control?

Use the TitleBar control when you want to integrate the title bar area with your app UI using customizations such as subtitles, Mica theming, and integrations with WinUI controls.

Anatomy

By default, the title bar shows only the system caption buttons. Other parts of the title bar are shown or hidden depending on associated property settings.

The title bar is divided into these areas:

- **Back button:** IsBackButtonEnabled, IsBackButtonVisible, BackRequested - A built-in back button for navigation.
- **Pane toggle button:** IsPaneToggleButtonVisible, PaneToggleRequested - This button is intended to be used in conjunction with the NavigationView control.
- **Left header:** LeftHeader
- **Icon:** IconSource
- **Title:** Title
- **Subtitle:** Subtitle
- **Content:** Content
- **Right header:** RightHeader
- **Min drag region:** This area is reserved next to the system caption buttons so that the user always has a place to grab the window for dragging.
- **System caption buttons:** These buttons are not part of the TitleBar control - it simply allocates space where the caption buttons appear, depending on RTL or LTR settings. Caption buttons and customizations are handled by the AppWindowTitleBar.

The layout is reversed when the FlowDirection is **RightToLeft**.

Create a title bar

✔ **Important APIs:** TitleBar class, Title property

Open the WinUI 3 Gallery app and see the TitleBar in action

> The **WinUI 3 Gallery** app includes interactive examples of most WinUI 3 controls, features, and functionality. Get the app from the Microsoft Store or get the source code on GitHub

This example creates a simple title bar that replaces the system title bar. It has a title, icon, and Mica theming.

XAML

```
<Window
    ...  >
    <Window.SystemBackdrop>
        <MicaBackdrop Kind="Base"/>
    </Window.SystemBackdrop>

    <Grid>
        <Grid.RowDefinitions>
            <RowDefinition Height="Auto" />
            <RowDefinition Height="*" />
```

```
        </Grid.RowDefinitions>

        <TitleBar x:Name="SimpleTitleBar"
                  Title="My App">
            <TitleBar.IconSource>
                <FontIconSource Glyph="&#xF4AA;"/>
            </TitleBar.IconSource>
        </TitleBar>

        <!-- App content -->
        <Frame x:Name="RootFrame" Grid.Row="1"/>
    </Grid>
</Window>
```

C#

```
public MainWindow()
{
    this.InitializeComponent();

    // Hides the default system title bar.
    ExtendsContentIntoTitleBar = true;
    // Replace system title bar with the WinUI TitleBar control.
    SetTitleBar(SimpleTitleBar);
}
```

Integration with NavigationView

The Navigation view has a built-in back button and pane toggle button. Fluent Design guidance recommends that these controls be placed in the title bar when a custom title bar is used.

This example demonstrates how to integrate the TitleBar control with a NavigationView control by hiding the back button and pane toggle button in the navigation view and using the corresponding buttons on the title bar instead.

XAML

```
<Grid>
    <Grid.RowDefinitions>
        <RowDefinition Height="Auto" />
        <RowDefinition Height="*" />
    </Grid.RowDefinitions>

    <TitleBar Title="My App"
              IsBackButtonVisible="True"
              IsBackButtonEnabled="{x:Bind RootFrame.CanGoBack,
Mode=OneWay}"
```

```
                BackRequested="TitleBar_BackRequested"
                IsPaneToggleButtonVisible="True"
                PaneToggleRequested="TitleBar_PaneToggleRequested">
    </TitleBar>

    <NavigationView x:Name="RootNavigationView" Grid.Row="1"
                    IsBackButtonVisible="Collapsed"
                    IsPaneToggleButtonVisible="False">
        <Frame x:Name="RootFrame" />
    </NavigationView>
</Grid>
```

C#

```
private void TitleBar_BackRequested(TitleBar sender, object args)
{
    if (RootFrame.CanGoBack)
    {
        RootFrame.GoBack();
    }
}

private void TitleBar_PaneToggleRequested(TitleBar sender, object args)
{
    RootNavigationView.IsPaneOpen = !RootNavigationView.IsPaneOpen;
}
```

UWP and WinUI 2

The TitleBar control is not available for UWP and WinUI 2. Instead, see Title bar customization (UWP apps).

Learn how to use tiles, badges, toasts, and notifications to provide entry points into your app and keep users up-to-date.

Toast notifications

Adaptive and interactive toast notifications let you create flexible notifications with text, images, and buttons/inputs.

Badge notifications

A notification badge conveys summary or status information specific to your app.

Push notifications

Push notifications let third-party developers send toast, tile, badge, and raw updates from their own cloud service.

Taskbar

Ask your user to pin your app to the taskbar to make it easier to find.

Title bar

Extend your app content into the title bar and add custom content.

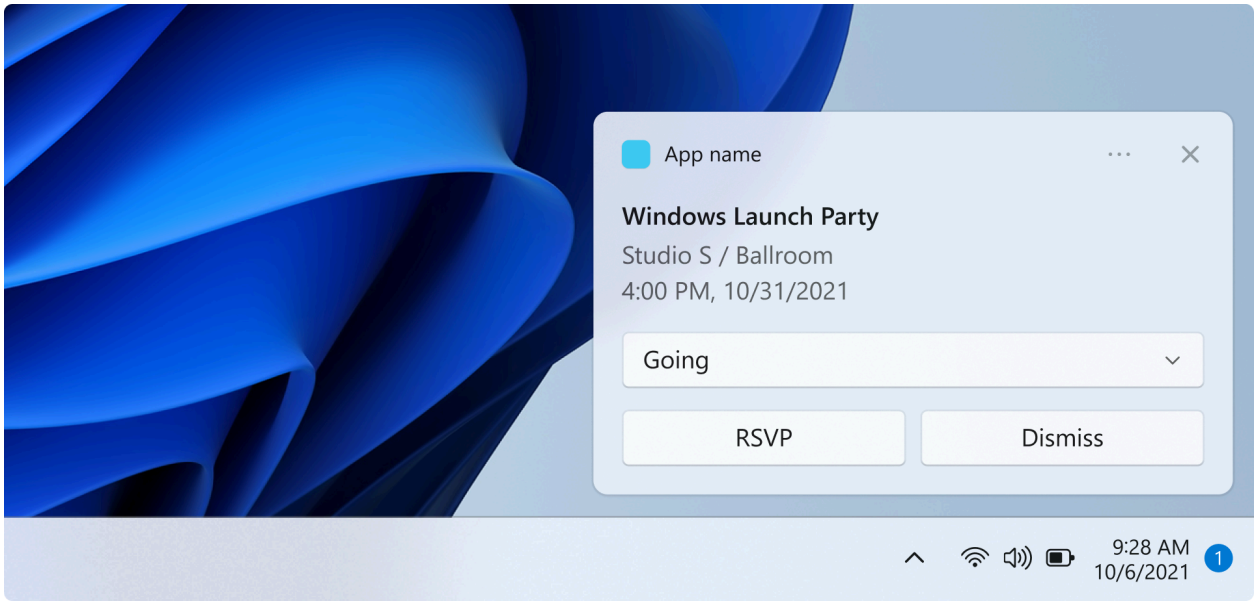
Toast notifications

Article • 11/26/2024



This section provides design and implementation guidance for toast notifications, which are messages that your app can construct and deliver to your user while they are not currently inside your app.

Toast notification UX and implementation guidance

- Toast notification UX guidance
- Send a local toast notification from C# apps
- Send a local toast notification from C++ UWP apps
- Send a local toast notification from Win32 C++ WRL apps
- Send a local toast notification from other types of unpackaged apps
- Toast content
- Toast content schema
- Schedule a toast notification

Additional toast notifications features

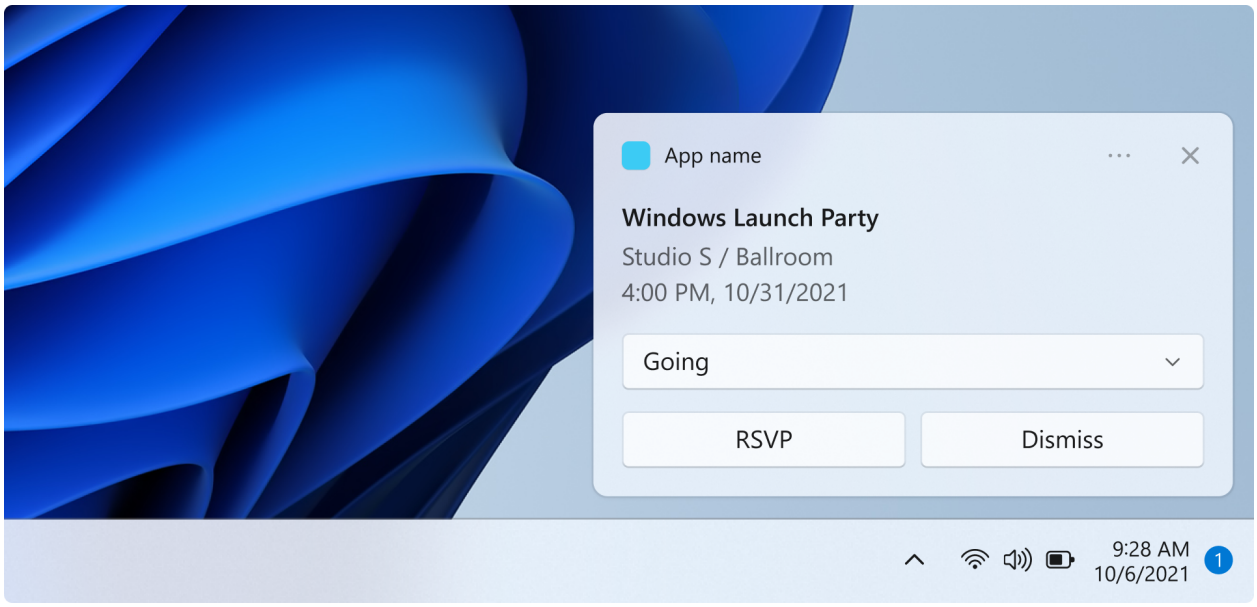
- Custom audio on toasts
- Toast progress bar and data binding
- Toast with pending update activation
- Custom timestamps on toasts
- Grouping toast notifications with collections

- Toast headers
- Notification listener: Access all notifications

Notifications design basics

Article • 06/03/2022

Drive user engagement with your app by providing personalized, actionable, and useful toast notifications. Toast notifications are the Windows notifications that appear in the lower right of the user's screen and the Notification Center (called Action Center in Windows 10). This article provides design guidance to consider as you plan and implement the toast notification experience for your app.

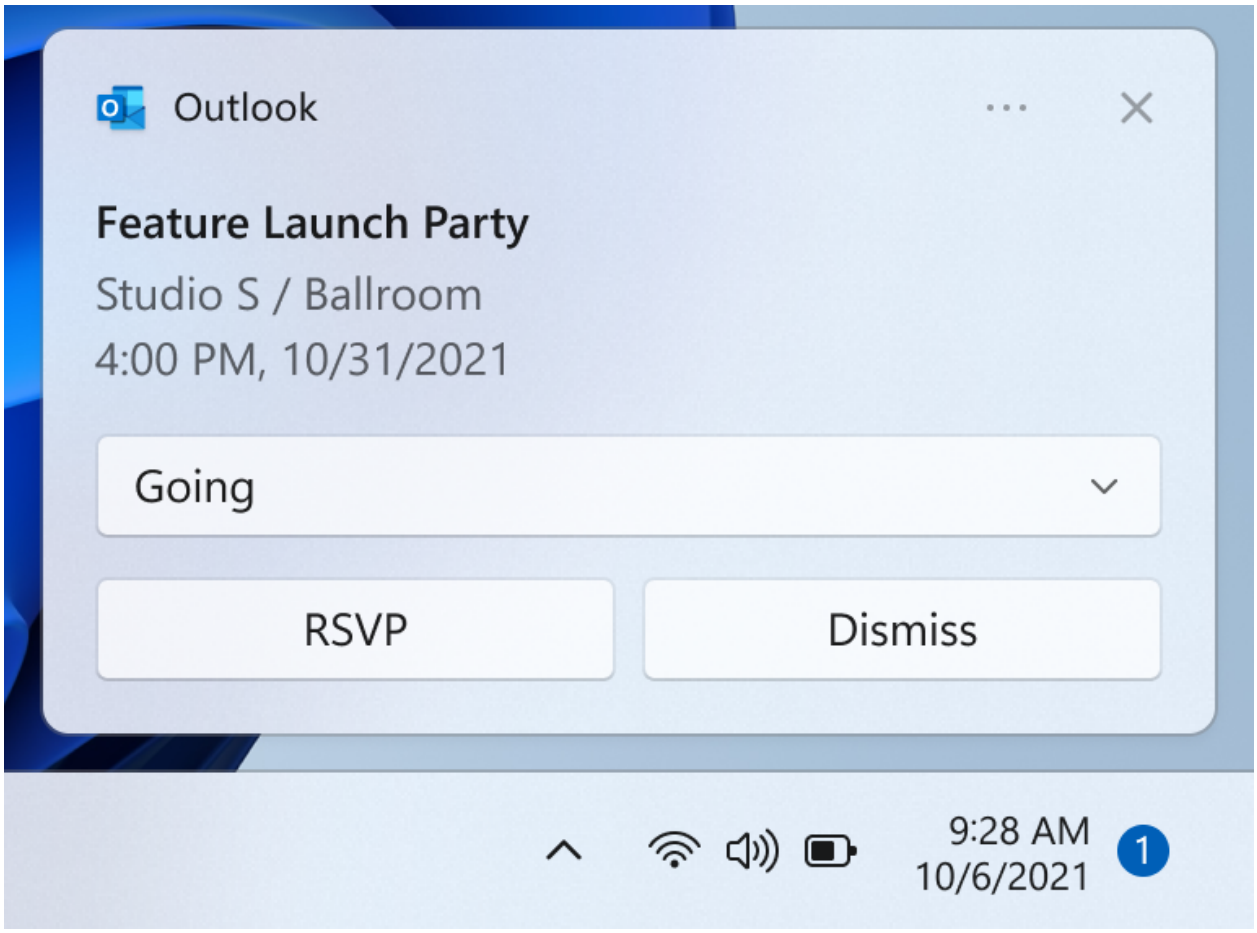


Notifications should be informative and valuable

Design your notifications to have clear intent so the user can quickly understand the purpose of the notification and stay in their flow. Consider the user scenarios your toast notifications are enabling and add elements to your notification that are appropriate for each scenario. Notifications should allow the user to save time, but shouldn't distract or create more work.

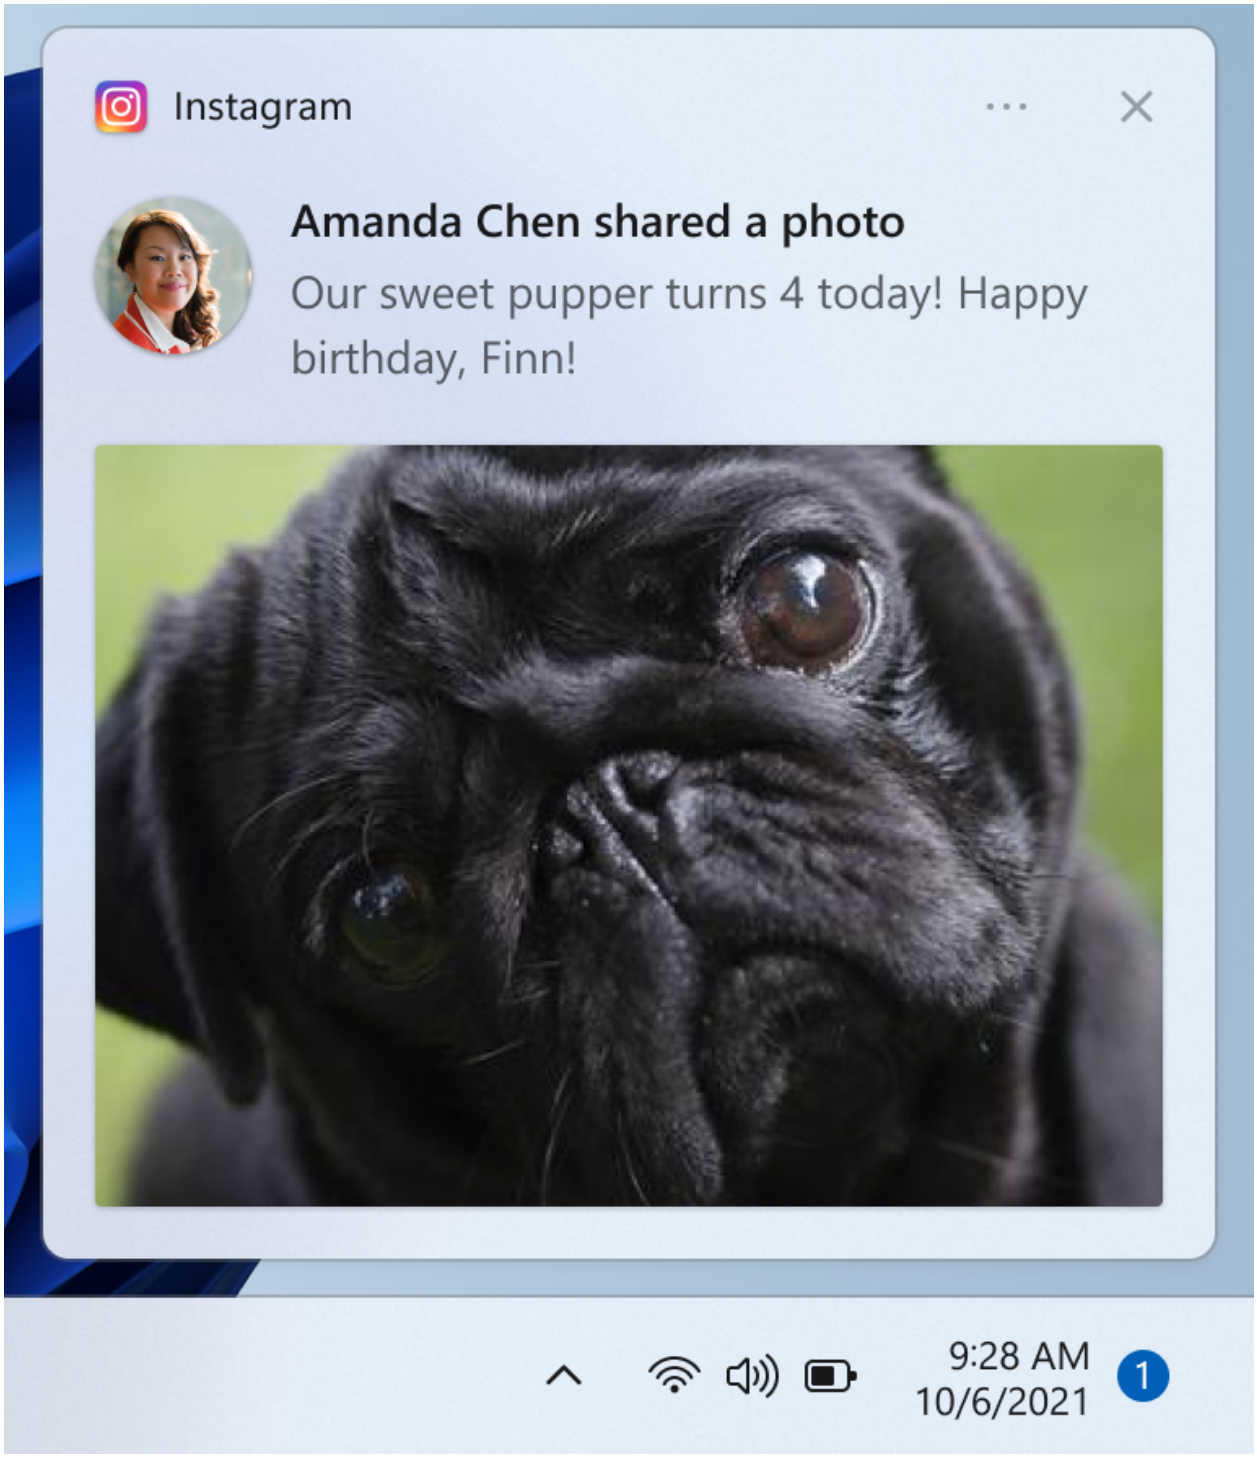
Choose the right notification UI elements

Consider which UI elements offer the most value to your user scenario. Is the purpose of the notification to allow the user to accomplish a task, or is it simply to get new information? The following section shows some example elements that you can use in your toast notifications.



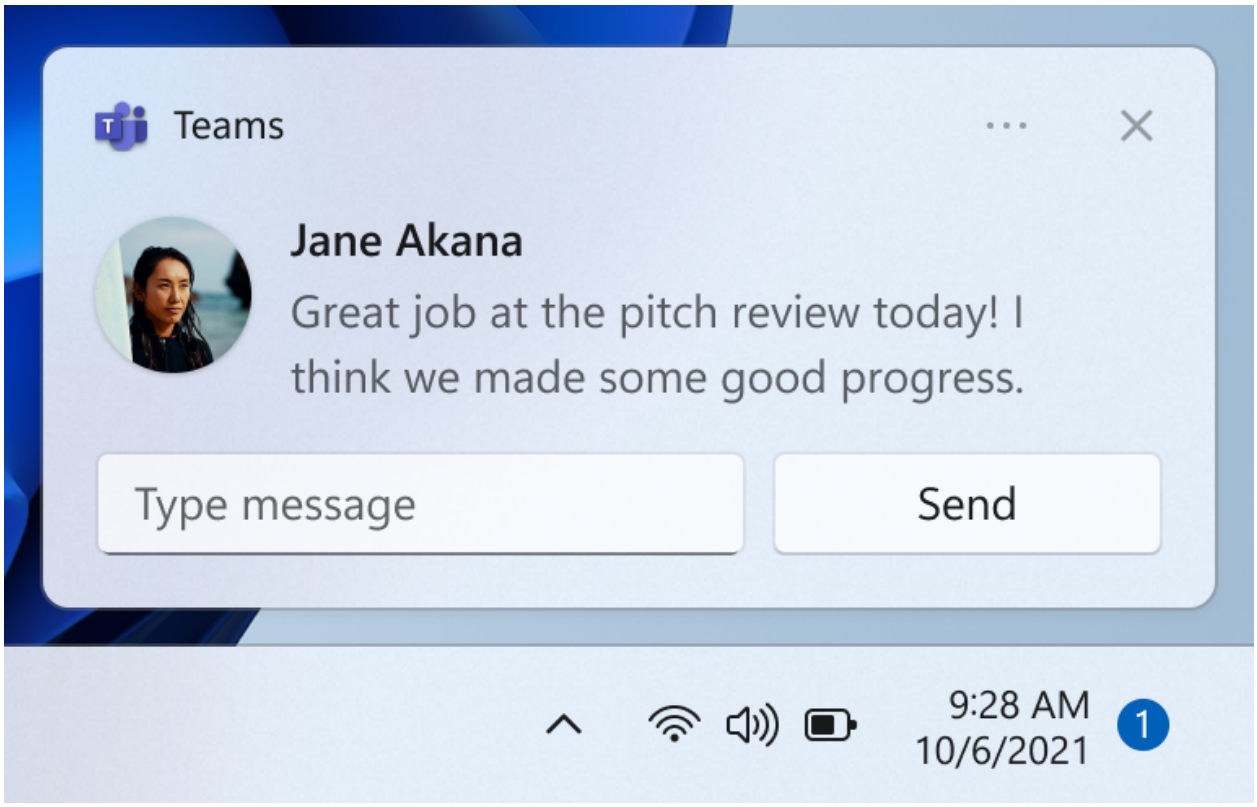
Buttons

Buttons trigger an immediate action. By adding buttons, the user can complete a task within the notification.



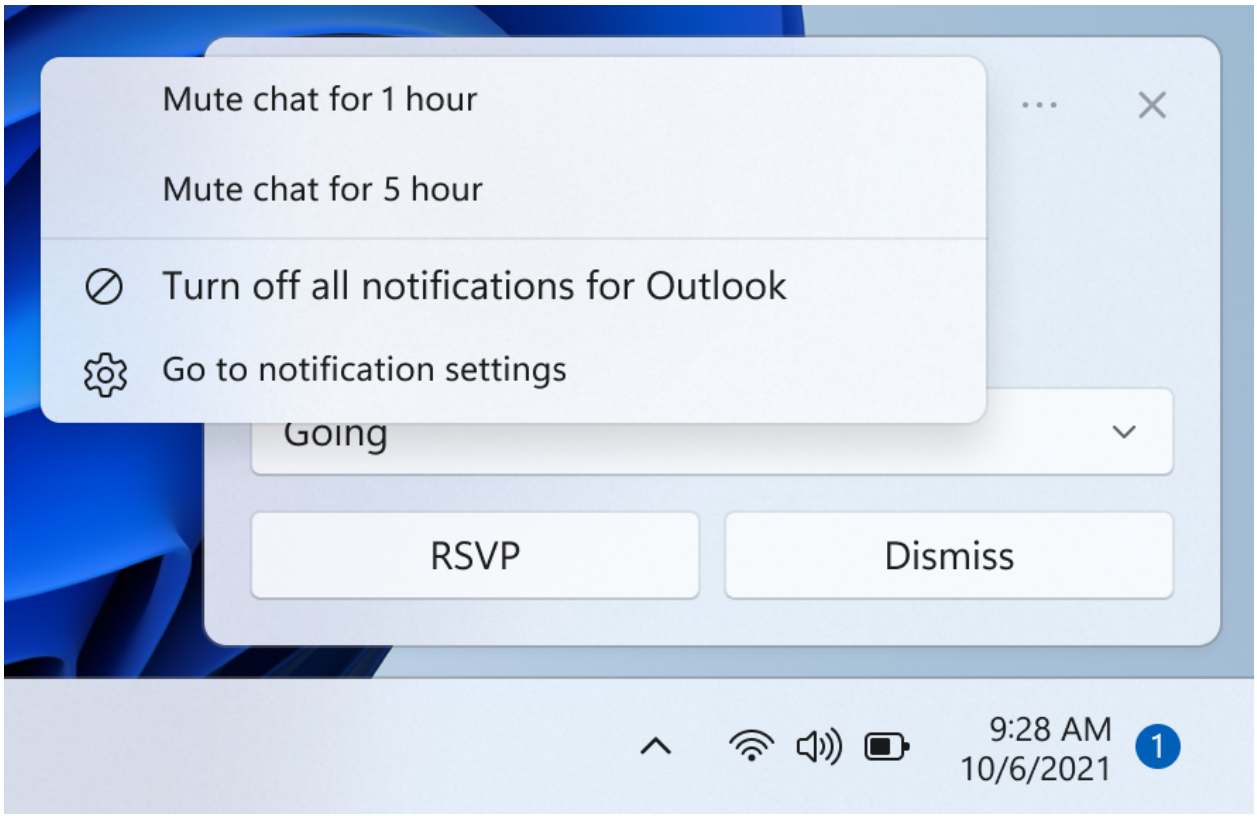
Images

Images can either be app logo override, inline, or hero. By adding images, the user can parse your content more quickly. Examples include adding an app logo override image depicting the sender's profile image to a chat or email notification.



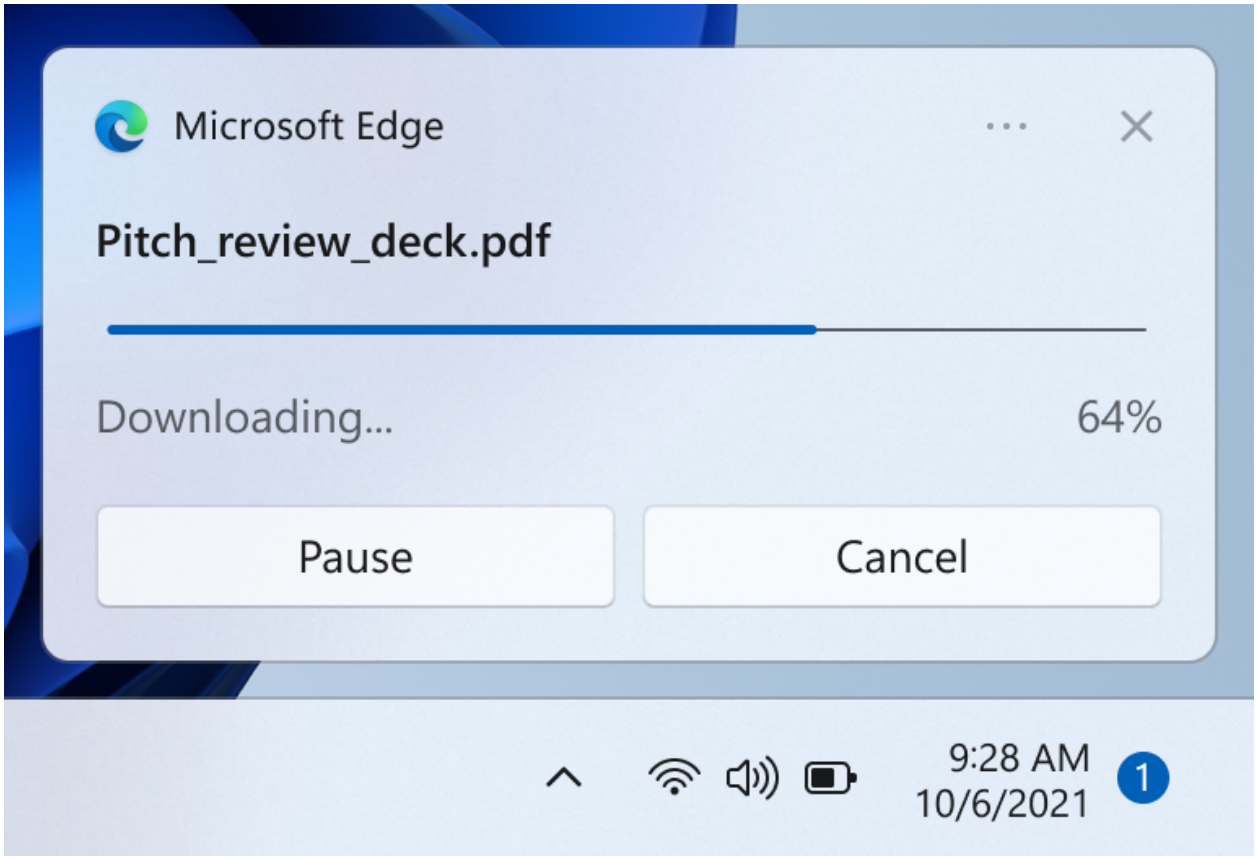
Quick replies

Quick reply boxes enable users to respond to messages without opening the app. Examples include adding quick reply boxes to a chat notification.



Context menu buttons

Context menu buttons give users more options on right-click on the notification or upon selection of the context menu icon. An example scenario is adding an option to mute a group chat for an hour.



Progress bars

Progress bars communicate status of long-running operations. By adding a progress bar, the user doesn't have to check back in your app for updates. Examples include communicating a file download or game update with a progress bar notification.

To see all of the UI elements that can be used in a notification, see Toast content.

Notifications should not be noisy

Users can easily be overloaded with too much information and get frustrated if they are being interrupted while they are trying to focus. Too many interruptions leads to users turning off this critical communication channel for your app.

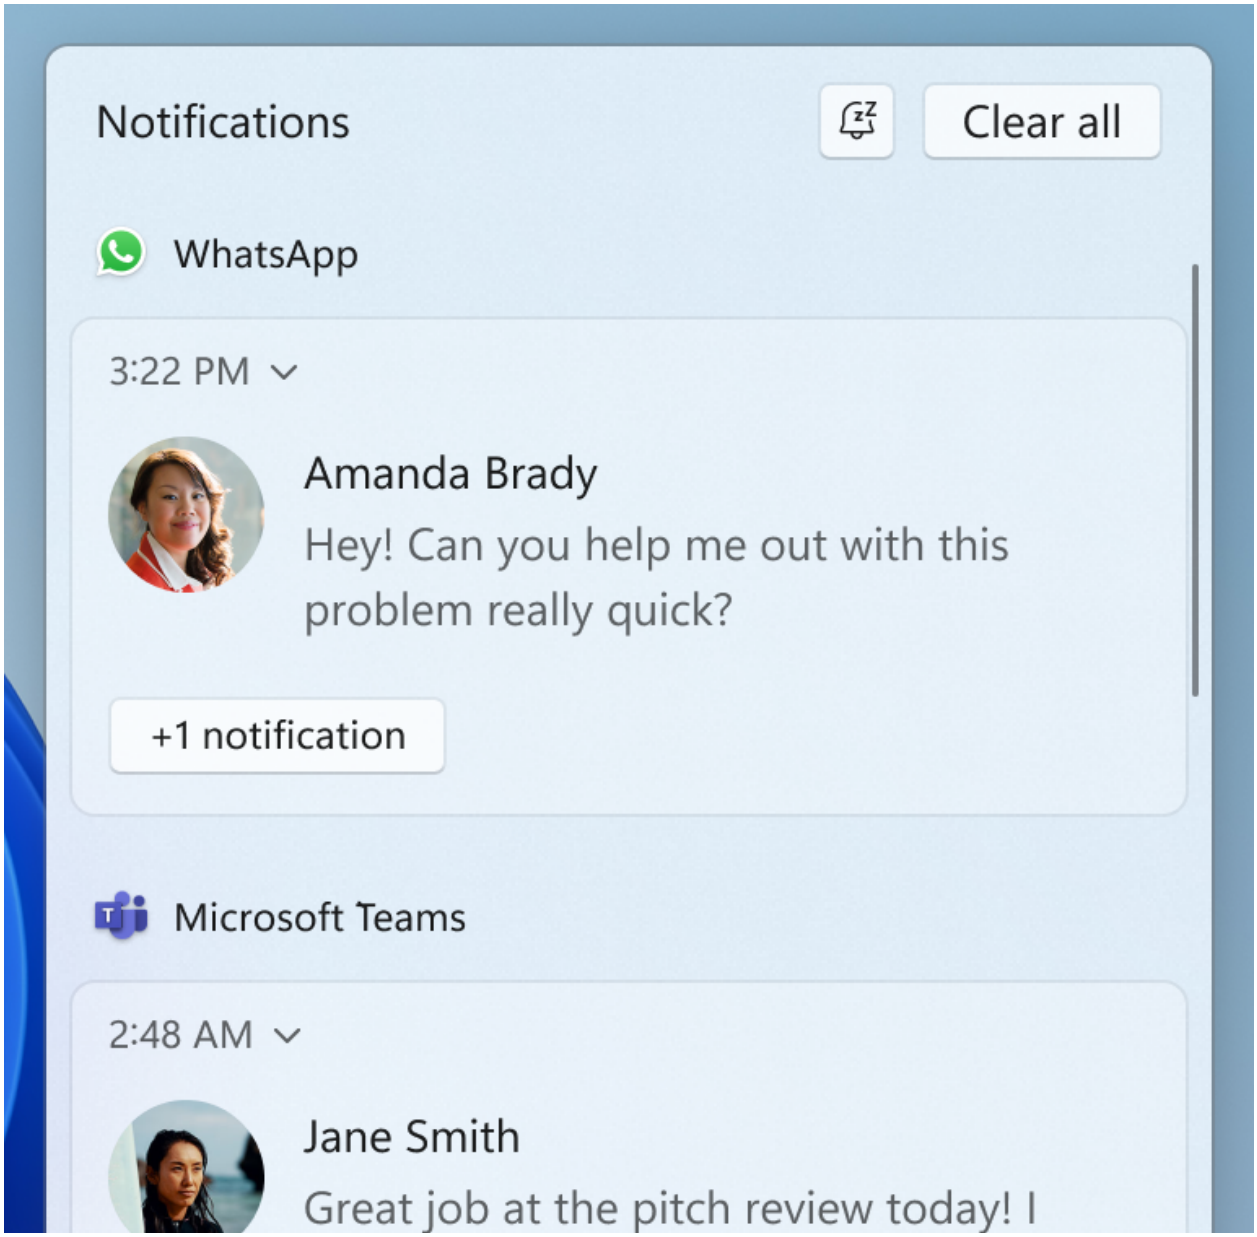
- One method of not interrupting the user but still communicating valuable information is by suppressing the notification, meaning the notification is automatically placed directly into the Notification Center without an alert.
- On Windows 11, Focus Sessions allow users to suppress extraneous notifications. You can use the FocusSessionManager API to detect if the user is in a Focus Session and adjust your app's notification behavior accordingly.

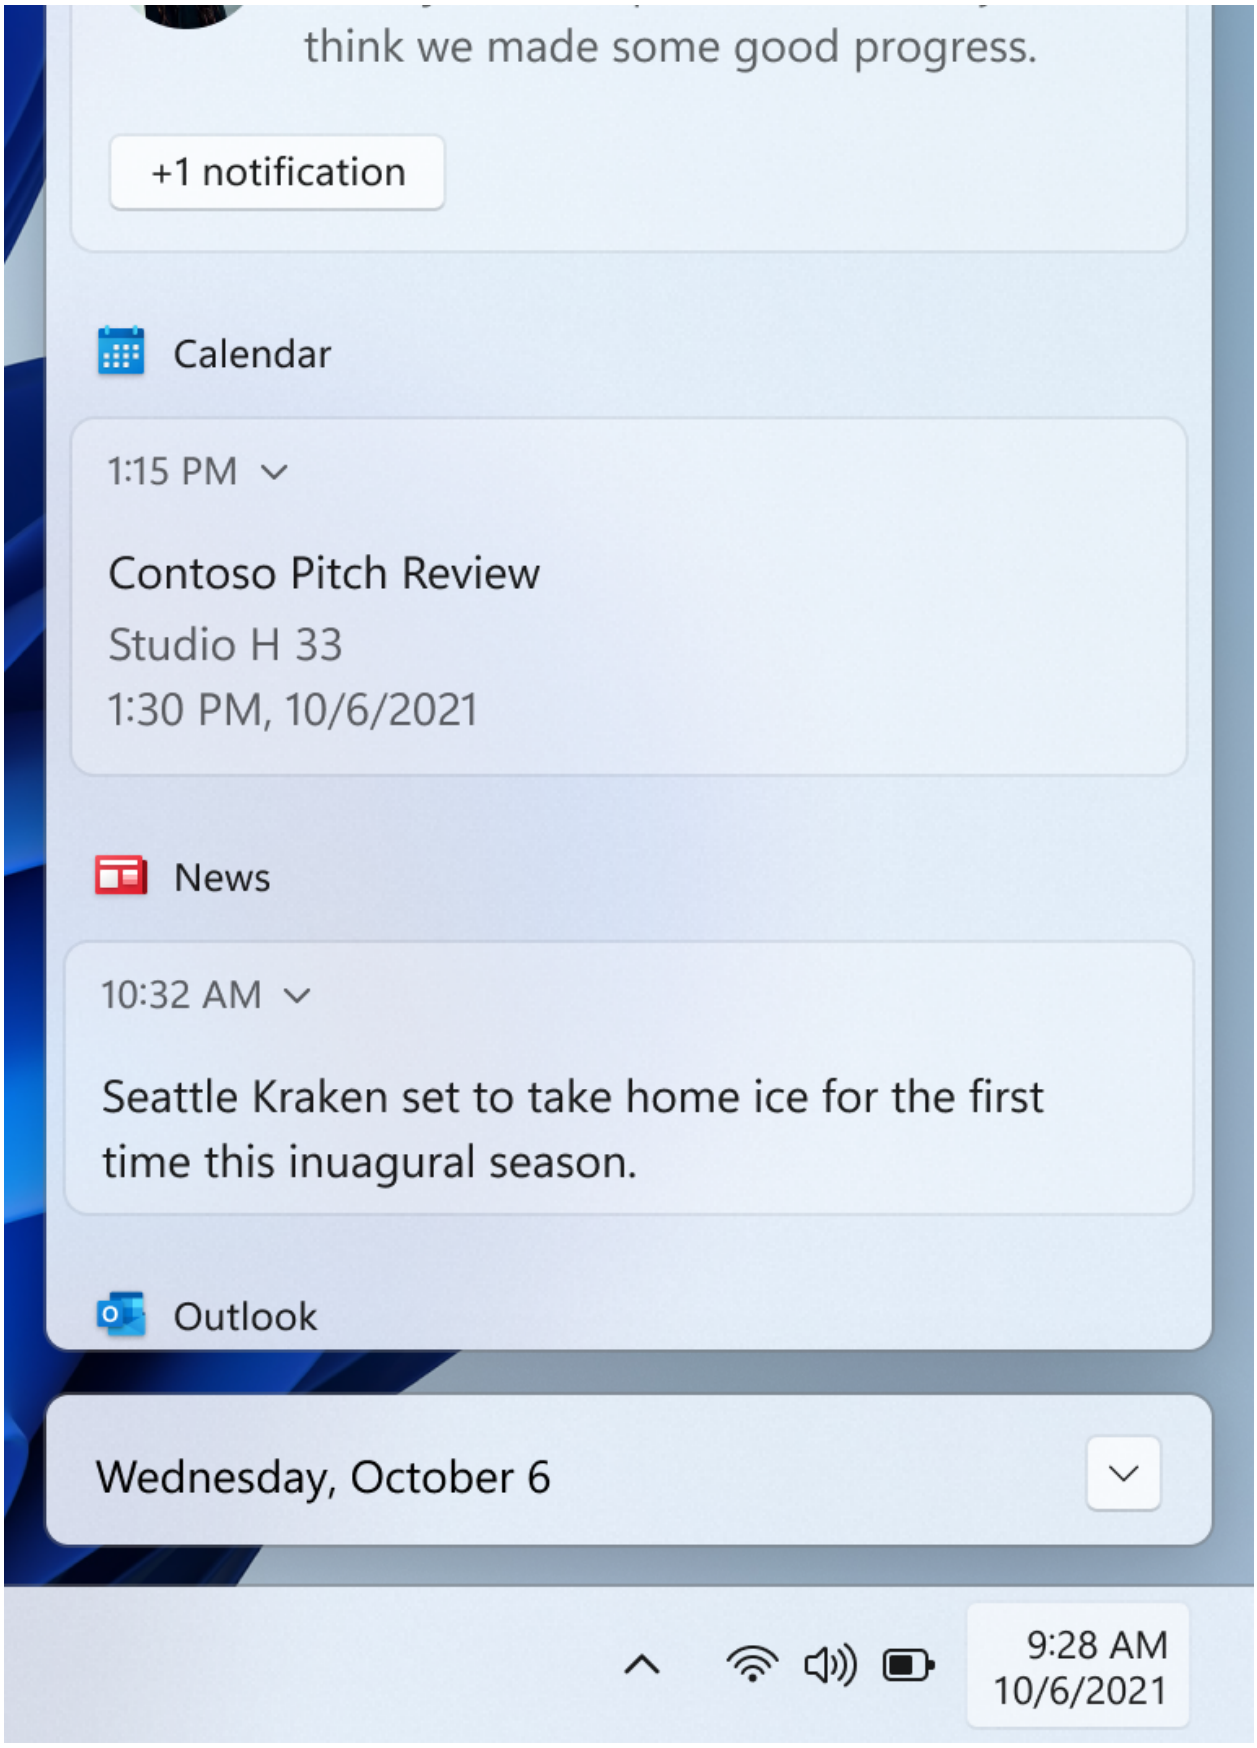
Respond to the user's intent

Just like the design of your notification UI, the behavior when the user clicks on the notification or on UI elements within the notification should be deliberate and consistent, and should engage the user in a clear task or scenario.

- If the user clicks on your notification to launch it, your app should launch in the notification's context.
- If the user clicks on a button in your notification, your app should launch in the context that is appropriate for the button's action
  - However, if the action is intended to be a background task, such as quick reply, your app should not launch.

Provide a consistent Notification Center experience





The Notification Center allows the user to view and respond to notifications after they have been displayed, or in the case of silent notifications, after they have been received but not displayed. It's important to keep Notification Center tidy by clearing out old notifications. You should also be sure to provide a consistent experience when removing notifications so the user feels confident they aren't missing information. Following

standard conventions for notification removal makes the notification experience predictable and intuitive for users.

The following are some example scenarios that illustrate strategies for clearing out old notifications from Notification Center:

- The user receives 10 new emails, and thus 10 new notifications. The user goes to the email app and views 10 emails, without interacting with the 10 notifications. After the user views the 10 emails, the email app removes the 10 notifications from the Notification Center. This also applies if the user has viewed the 10 emails elsewhere, such as their phone or website.
- The user receives 10 new chat messages from one user, and thus 10 new notifications. The user selects one of these chat notifications, which launches the chat. After the user views the chat, the app removes the 9 remaining notifications from the Notification Center.

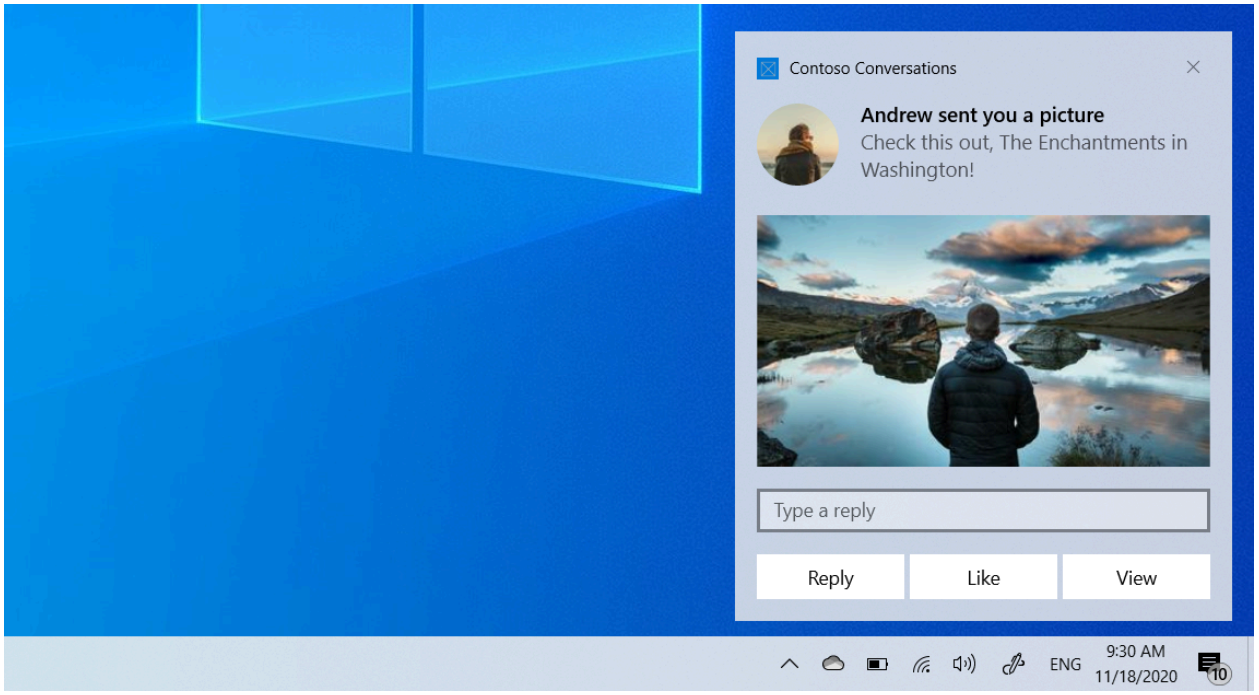
Developer guidance for notifications

Send a local toast notification from a C# app

Article • 11/27/2024

A toast notification is a message that your app can construct and deliver to your user while they are not currently inside your app.



This quickstart walks you through the steps to create, deliver, and display a Windows 10 or Windows 11 toast notification using rich content and interactive actions. This quickstart uses local notifications, which are the simplest notification to implement. All types of apps (WPF, UWP, WinForms, console) can send notifications!

> **ⓘ Important**
>
> If you're writing a C++ app, please see the C++ UWP or C++ WRL documentation.

Step 1: Install NuGet package

Within your Visual Studio solution, right click your project, click "*Manage NuGet Packages...*" and search for and install the `Microsoft.Toolkit.Uwp.Notifications` NuGet package version 7.0 or greater.

> **ⓘ Important**

.NET Framework desktop apps that still use packages.config must migrate to PackageReference, otherwise the Windows SDKs won't be referenced correctly. In your project, right-click on "References", and click "Migrate packages.config to PackageReference".

.NET Core 3.0 WPF apps must update to .NET Core 3.1, otherwise the APIs will be absent.

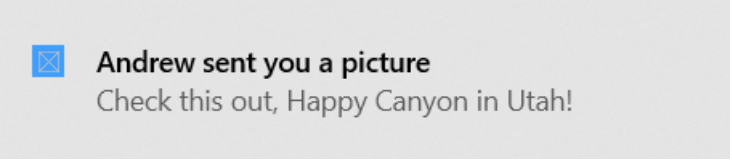
.NET apps must use one of the Windows TFMs, otherwise the toast sending and management APIs like `Show()` will be missing. Set your TFM to `net6.0-windows10.0.17763.0` or later.

Our code sample will use this package. This package allows you to create toast notifications without using XML, and also allows desktop apps to send toasts.

Step 2: Send a toast

In Windows 10 and Windows 11, your toast notification content is described using an adaptive language that allows great flexibility with how your notification looks. For more information, see the toast content documentation.

We'll start with a simple text-based notification. Construct the notification content (using the Notifications library), and show the notification! Note that the namespace is `Microsoft.Toolkit.Uwp.Notifications`.



C#

```
// Requires Microsoft.Toolkit.Uwp.Notifications NuGet package version 7.0 or greater
new ToastContentBuilder()
    .AddArgument("action", "viewConversation")
    .AddArgument("conversationId", 9813)
    .AddText("Andrew sent you a picture")
    .AddText("Check this out, The Enchantments in Washington!")
    .Show(); // Not seeing the Show() method? Make sure you have version 7.0, and if you're using .NET 6 (or later), then your TFM must be net6.0-windows10.0.17763.0 or greater
```

Try running this code and you should see the notification appear!

Step 3: Handling activation

After showing a notification, you likely need to handle the user clicking the notification (whether that means bringing up specific content after the user clicks it, opening your app in general, or performing an action when the user clicks the notification).

The steps for handling activation differ for UWP, and for packaged and unpackaged desktop apps.

UWP

When the user clicks your notification (or a button on the notification with foreground activation), your app's **App.xaml.cs OnActivated** will be invoked, and the arguments you added will be returned.

App.xaml.cs

C#

```
protected override void OnActivated(IActivatedEventArgs e)
{
    // Handle notification activation
    if (e is ToastNotificationActivatedEventArgs toastActivationArgs)
    {
        // Obtain the arguments from the notification
        ToastArguments args =
ToastArguments.Parse(toastActivationArgs.Argument);

        // Obtain any user input (text boxes, menu selections) from the
notification
        ValueSet userInput = toastActivationArgs.UserInput;

        // TODO: Show the corresponding content
    }
}
```

ⓘ Important

You must initialize your frame and activate your window just like your **OnLaunched** code. **OnLaunched is NOT called if the user clicks on your toast**, even if your app was closed and is launching for the first time. We often recommend combining **OnLaunched** and **OnActivated** into your own `OnLaunchedOrActivated` method since the same initialization needs to occur in both.

Step 4: Handling uninstallation

UWP

You don't need to do anything! When UWP apps are uninstalled, all notifications and any other related resources are automatically cleaned up.

Adding images

You can add rich content to notifications. We'll add an inline image and a profile (app logo override) image.

> **Note**
>
> Images can be used from the app's package, the app's local storage, or from the web. As of the Fall Creators Update, web images can be up to 3 MB on normal connections and 1 MB on metered connections. On devices not yet running the Fall Creators Update, web images must be no larger than 200 KB.

> **Important**
>
> Http images are supported only in packaged apps that have the internet capability in their manifest. Unpackaged apps don't support http images; you must download the image to your local app data, and reference it locally.

C#

```
// Construct the content and show the toast!
new ToastContentBuilder()
    ...

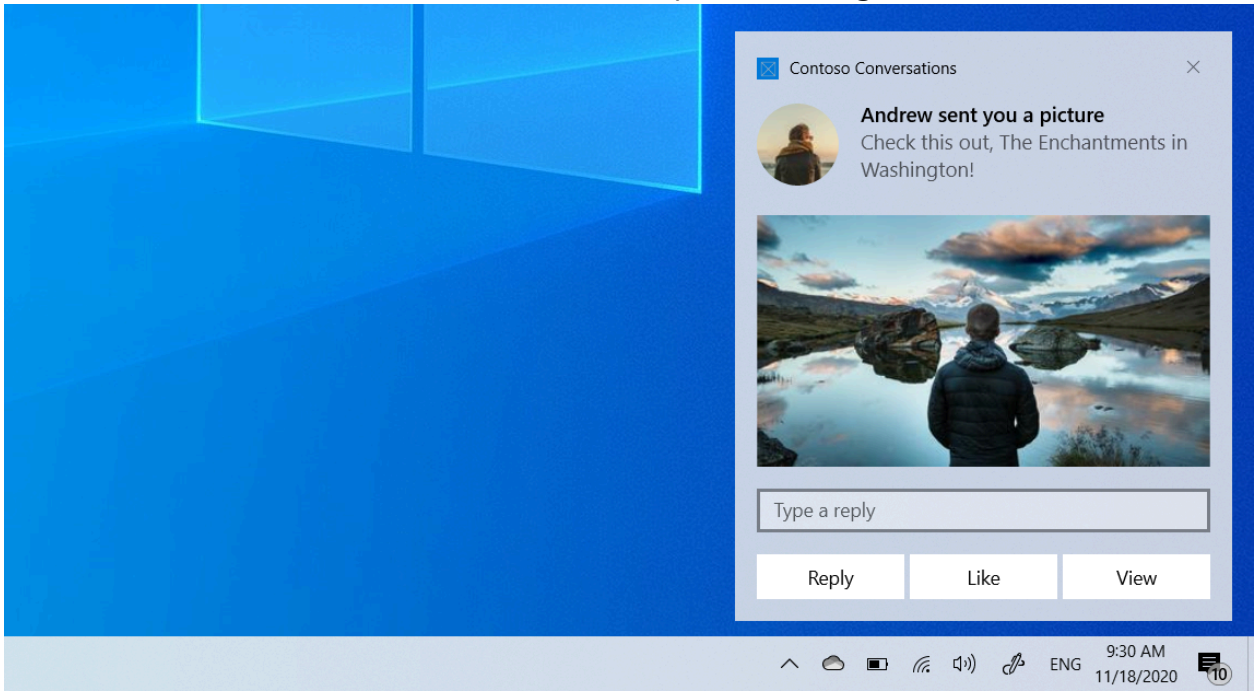
    // Inline image
    .AddInlineImage(new Uri("https://picsum.photos/360/202?image=883"))

    // Profile (app logo override) image
    .AddAppLogoOverride(new Uri("ms-appdata:///local/Andrew.jpg"),
ToastGenericAppLogoCrop.Circle)

    .Show();
```

Adding buttons and inputs

You can add buttons and inputs to make your notifications interactive. Buttons can launch your foreground app, a protocol, or your background task. We'll add a reply text box, a "Like" button, and a "View" button that opens the image.



C#

```
int conversationId = 384928;

// Construct the content
new ToastContentBuilder()
    .AddArgument("conversationId", conversationId)
    ...

    // Text box for replying
    .AddInputTextBox("tbReply", placeHolderContent: "Type a response")

    // Buttons
```

```
    .AddButton(new ToastButton()
        .SetContent("Reply")
        .AddArgument("action", "reply")
        .SetBackgroundActivation())

    .AddButton(new ToastButton()
        .SetContent("Like")
        .AddArgument("action", "like")
        .SetBackgroundActivation())

    .AddButton(new ToastButton()
        .SetContent("View")
        .AddArgument("action", "viewImage")
        .AddArgument("imageUrl", image.ToString()))

    .Show();
```

The activation of foreground buttons are handled in the same way as the main toast body (your App.xaml.cs OnActivated will be called).

Note that arguments added to the top-level toast (like conversation ID) will also be returned when the buttons are clicked, as long as buttons use the AddArgument API as seen above (if you custom assign arguments on a button, the top-level arguments won't be included).

Handling background activation

UWP

When you specify background activation on your toast (or on a button inside the toast), your background task will be executed instead of activating your foreground app.

For more information on background tasks, please see Support your app with background tasks.

If you are targeting build 14393 or later, you can use in-process background tasks, which greatly simplify things. Note that in-process background tasks will fail to run on older versions of Windows. We'll use an in-process background task in this code sample.

C#

```
const string taskName = "ToastBackgroundTask";

// If background task is already registered, do nothing
```

```
if (BackgroundTaskRegistration.AllTasks.Any(i =>
i.Value.Name.Equals(taskName)))
    return;

// Otherwise request access
BackgroundAccessStatus status = await
BackgroundExecutionManager.RequestAccessAsync();

// Create the background task
BackgroundTaskBuilder builder = new BackgroundTaskBuilder()
{
    Name = taskName
};

// Assign the toast action trigger
builder.SetTrigger(new ToastNotificationActionTrigger());

// And register the task
BackgroundTaskRegistration registration = builder.Register();
```

Then in your App.xaml.cs, override the OnBackgroundActivated method. You can then retrieve the pre-defined arguments and user input, similar to the foreground activation.

App.xaml.cs

C#

```
protected override async void
OnBackgroundActivated(BackgroundActivatedEventArgs args)
{
    var deferral = args.TaskInstance.GetDeferral();

    switch (args.TaskInstance.Task.Name)
    {
        case "ToastBackgroundTask":
            var details = args.TaskInstance.TriggerDetails as
ToastNotificationActionTriggerDetail;
            if (details != null)
            {
                ToastArguments arguments =
ToastArguments.Parse(details.Argument);
                var userInput = details.UserInput;

                // Perform tasks
            }
            break;
    }

    deferral.Complete();
}
```

Set an expiration time

In Windows 10, all toast notifications go in Action Center after they are dismissed or ignored by the user, so users can look at your notification after the popup is gone.

However, if the message in your notification is only relevant for a period of time, you should set an expiration time on the toast notification so the users do not see stale information from your app. For example, if a promotion is only valid for 12 hours, set the expiration time to 12 hours. In the code below, we set the expiration time to be 2 days.

> ⓘ **Note**
>
> The default and maximum expiration time for local toast notifications is 3 days.

C#

```
// Create toast content and show the toast!
new ToastContentBuilder()
    .AddText("Expires in 2 days...")
    .Show(toast =>
    {
        toast.ExpirationTime = DateTime.Now.AddDays(2);
    });
```

Provide a primary key for your toast

If you want to programmatically remove or replace the notification you send, you need to use the Tag property (and optionally the Group property) to provide a primary key for your notification. Then, you can use this primary key in the future to remove or replace the notification.

To see more details on replacing/removing already delivered toast notifications, please see Quickstart: Managing toast notifications in action center (XAML).

Tag and Group combined act as a composite primary key. Group is the more generic identifier, where you can assign groups like "wallPosts", "messages", "friendRequests", etc. And then Tag should uniquely identify the notification itself from within the group. By using a generic group, you can then remove all notifications from that group by using the RemoveGroup API.

C#

```
// Create toast content and show the toast!
new ToastContentBuilder()
    .AddText("New post on your wall!")
    .Show(toast =>
    {
        toast.Tag = "18365";
        toast.Group = "wallPosts";
    });
```

Clear your notifications

Apps are responsible for removing and clearing their own notifications. When your app is launched, we do NOT automatically clear your notifications.

Windows will only automatically remove a notification if the user explicitly clicks the notification.

Here's an example of what a messaging app should do...

1. User receives multiple toasts about new messages in a conversation
2. User taps one of those toasts to open the conversation
3. The app opens the conversation and then clears all toasts for that conversation (by using RemoveGroup on the app-supplied group for that conversation)
4. User's Action Center now properly reflects the notification state, since there are no stale notifications for that conversation left in Action Center.

To learn about clearing all notifications or removing specific notifications, see Quickstart: Managing toast notifications in action center (XAML).

C#

```
ToastNotificationManagerCompat.History.Clear();
```

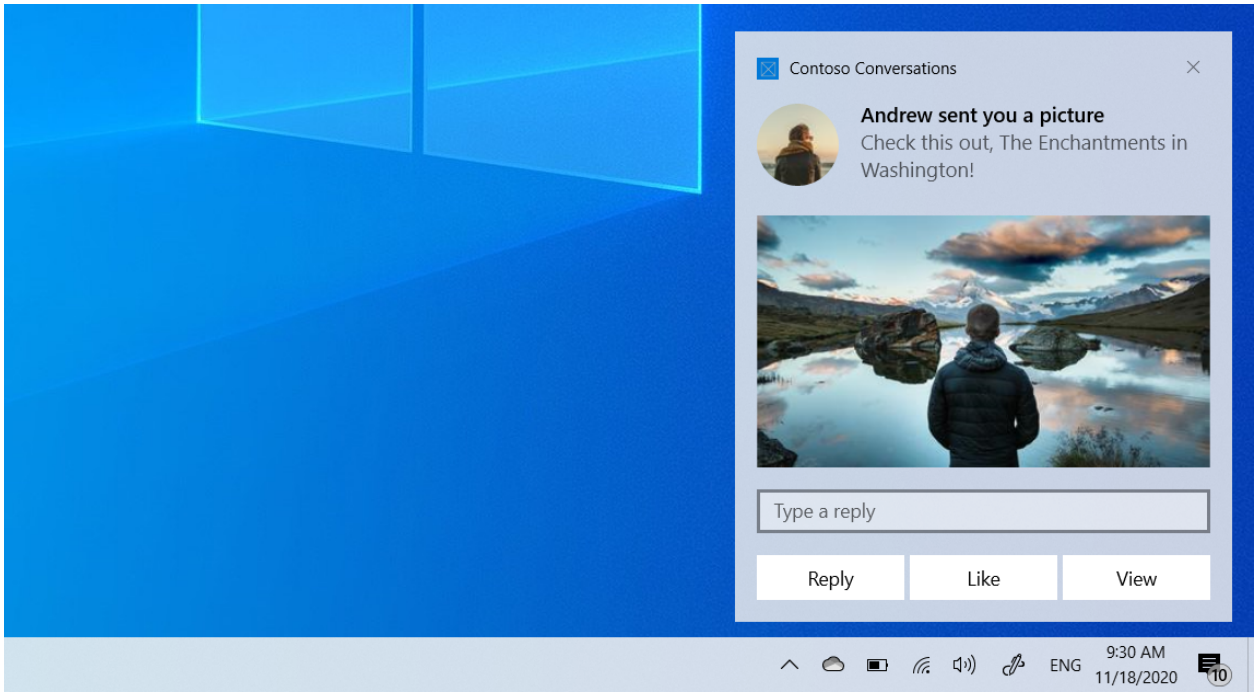
Send a local toast notification from C++ UWP apps

Article • 10/27/2022

A toast notification is a message that your app can construct and deliver to your user while they are not currently inside your app.



This quickstart walks you through the steps to create, deliver, and display a Windows 10 or Windows 11 toast notification using rich content and interactive actions. This quickstart uses local notifications, which are the simplest notification to implement. All types of apps (WPF, UWP, WinForms, console) can send notifications!

> **ⓘ Important**
>
> If you're writing a C++ non-UWP app, please see the **C++ WRL** documentation. If you're writing a C# app, please see the **C# documentation**.

Step 1: Install NuGet package

You can create toast notifications with the Windows Community Toolkit (WCT)'s builder syntax OR with XML. If you prefer the latter, please skip to **Step 2** and refer to the **Without builder syntax** code examples.

Within your Visual Studio solution, right click your project, click "*Manage NuGet Packages...*" and search for and install the `Microsoft.Toolkit.Uwp.Notifications` NuGet

package version 7.0 or greater.

Our **Builder syntax** code examples will use this package. This package allows you to create toast notifications without using XML.

Step 2: Add namespace declarations

Builder syntax

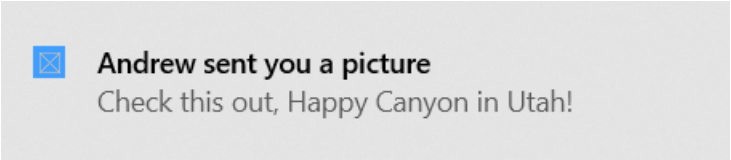
C++

```
using namespace Microsoft::Toolkit::Uwp::Notifications;
```

Step 3: Send a toast

In Windows 10 and Windows 11, your toast notification content is described using an adaptive language that allows great flexibility with how your notification looks. For more information, see the toast content documentation.

We'll start with a simple text-based notification. Construct the notification content (using the Notifications library), and show the notification! Note that the namespace is `Microsoft.Toolkit.Uwp.Notifications`.



If you are not using the WCT Notifications library builder syntax, you will instead construct the XML toast template, populate it with text and values, construct the notification, and show it.

Builder syntax

C++

```
// Construct the content and show the toast!
(ref new ToastContentBuilder())
    ->AddArgument("action", "viewConversation")
    ->AddArgument("conversationId", 9813)
    ->AddText("Andrew sent you a picture")
    ->AddText("Check this out, The Enchantments in Washington!")
    ->Show();
```

Step 4: Handling activation

When the user clicks your notification (or a button on the notification with foreground activation), your app's **App.xaml.cpp OnActivated** will be invoked.

App.xaml.cpp

C++

```
void App::OnActivated(IActivatedEventArgs^ e)
{
    // Handle notification activation
    if (e->Kind == ActivationKind::ToastNotification)
    {
        ToastNotificationActivatedEventArgs^ toastActivationArgs =
(ToastNotificationActivatedEventArgs^)e;

        // Obtain the arguments from the notification
        ToastArguments^ args = ToastArguments::Parse(toastActivationArgs-
>Argument);

        // Obtain any user input (text boxes, menu selections) from the
notification
        auto userInput = toastActivationArgs->UserInput;

        // TODO: Show the corresponding content
    }
}
```

> **ⓘ Important**
>
> You must initialize your frame and activate your window just like your **OnLaunched** code. **OnLaunched is NOT called if the user clicks on your toast**, even if your app was closed and is launching for the first time. We often recommend combining **OnLaunched** and **OnActivated** into your own `OnLaunchedOrActivated` method since the same initialization needs to occur in both.

Activation in depth

The first step in making your notifications actionable is to add some launch args to your notification, so that your app can know what to launch when the user clicks the notification (in this case, we're including some information that later tells us we should open a conversation, and we know which specific conversation to open).

Builder syntax

C++

```
// Construct the content and show the toast!
(ref new ToastContentBuilder())

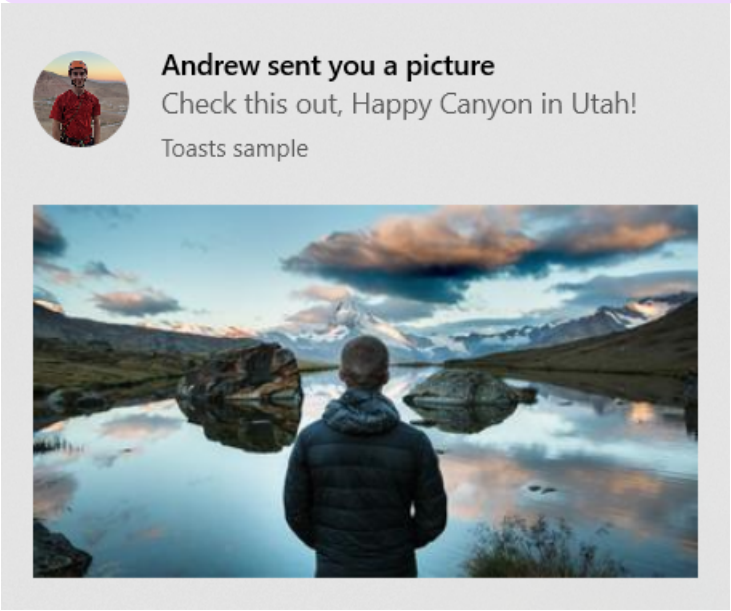
    // Arguments returned when user taps body of notification
    ->AddArgument("action", "viewConversation")
    ->AddArgument("conversationId", 9813)

    ->AddText("Andrew sent you a picture")
    ->Show();
```

Adding images

You can add rich content to notifications. We'll add an inline image and a profile (app logo override) image.

> **Note**
>
> Images can be used from the app's package, the app's local storage, or from the web. As of the Fall Creators Update, web images can be up to 3 MB on normal connections and 1 MB on metered connections. On devices not yet running the Fall Creators Update, web images must be no larger than 200 KB.



Builder syntax

C++

```
// Construct the content and show the toast!
(ref new ToastContentBuilder())
    ...

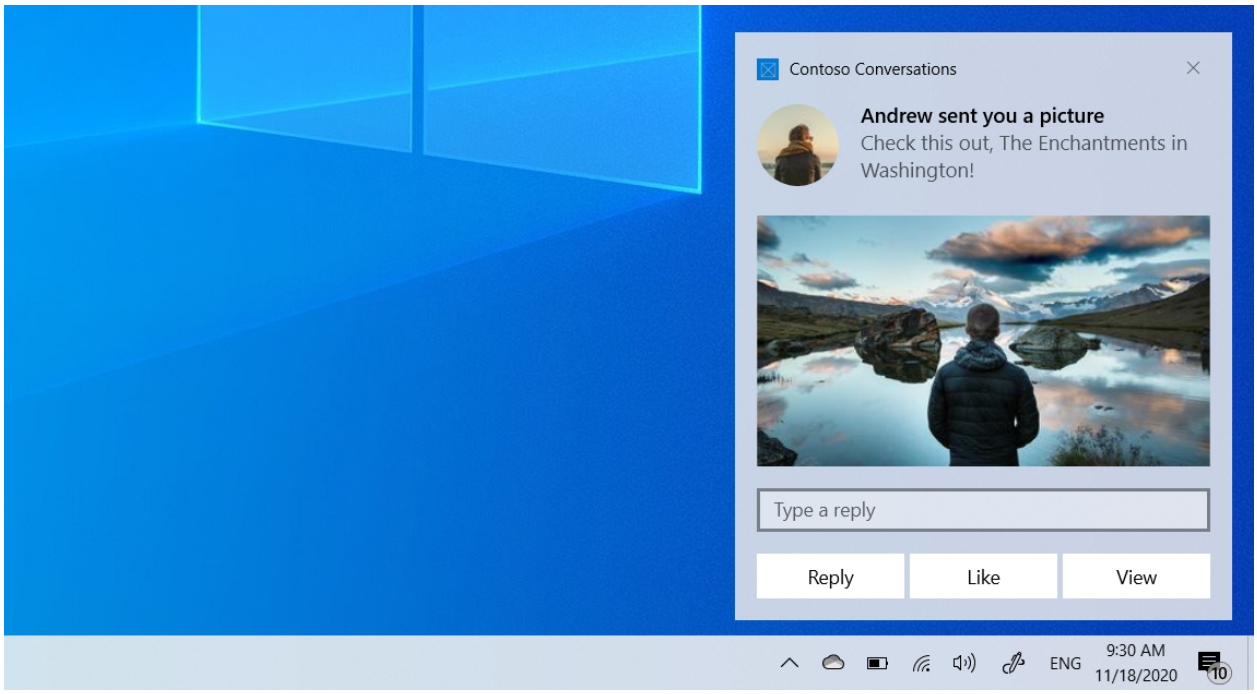
    // Inline image
    ->AddInlineImage(ref new Uri("https://picsum.photos/360/202?
image=883"))

    // Profile (app logo override) image
    ->AddAppLogoOverride(ref new Uri("ms-appdata:///local/Andrew.jpg"),
ToastGenericAppLogoCrop::Circle)

    ->Show();
```

Adding buttons and inputs

You can add buttons and inputs to make your notifications interactive. Buttons can launch your foreground app, a protocol, or your background task. We'll add a reply text box, a "Like" button, and a "View" button that opens the image.



Builder syntax

C++

```
// Construct the content
(ref new ToastContentBuilder())
    ->AddArgument("conversationId", 9813)
    ...
```

```
    // Text box for replying
    ->AddInputTextBox("tbReply", "Type a response")

    // Buttons
    ->AddButton((ref new ToastButton())
        ->SetContent("Reply")
        ->AddArgument("action", "reply")
        ->SetBackgroundActivation())

    ->AddButton((ref new ToastButton())
        ->SetContent("Like")
        ->AddArgument("action", "like")
        ->SetBackgroundActivation())

    ->AddButton((ref new ToastButton())
        ->SetContent("View")
        ->AddArgument("action", "view"))

    ->Show();
```

The activation of foreground buttons are handled in the same way as the main toast body (your App.xaml.cpp OnActivated will be called).

Handling background activation

When you specify background activation on your toast (or on a button inside the toast), your background task will be executed instead of activating your foreground app.

For more information on background tasks, please see Support your app with background tasks.

If you are targeting build 14393 or later, you can use in-process background tasks, which greatly simplify things. Note that in-process background tasks will fail to run on older versions of Windows. We'll use an in-process background task in this code sample.

C#

```
const string taskName = "ToastBackgroundTask";

// If background task is already registered, do nothing
if (BackgroundTaskRegistration.AllTasks.Any(i =>
i.Value.Name.Equals(taskName)))
    return;

// Otherwise request access
BackgroundAccessStatus status = await
BackgroundExecutionManager.RequestAccessAsync();
```

```
// Create the background task
BackgroundTaskBuilder builder = new BackgroundTaskBuilder()
{
    Name = taskName
};

// Assign the toast action trigger
builder.SetTrigger(new ToastNotificationActionTrigger());

// And register the task
BackgroundTaskRegistration registration = builder.Register();
```

Then in your App.xaml.cs, override the OnBackgroundActivated method. You can then retrieve the pre-defined arguments and user input, similar to the foreground activation.

App.xaml.cs

C#

```
protected override async void
OnBackgroundActivated(BackgroundActivatedEventArgs args)
{
    var deferral = args.TaskInstance.GetDeferral();

    switch (args.TaskInstance.Task.Name)
    {
        case "ToastBackgroundTask":
            var details = args.TaskInstance.TriggerDetails as
ToastNotificationActionTriggerDetail;
            if (details != null)
            {
                string arguments = details.Argument;
                var userInput = details.UserInput;

                // Perform tasks
            }
            break;
    }

    deferral.Complete();
}
```

Set an expiration time

In Windows 10 and 11, all toast notifications go in Action Center after they are dismissed or ignored by the user, so users can look at your notification after the popup is gone.

However, if the message in your notification is only relevant for a period of time, you should set an expiration time on the toast notification so the users do not see stale information from your app. For example, if a promotion is only valid for 12 hours, set the expiration time to 12 hours. In the code below, we set the expiration time to be 2 days.

> **Note**
>
> The default and maximum expiration time for local toast notifications is 3 days.

C++

```
// Create toast content and show the toast!
(ref new ToastContentBuilder())
    ->AddText("Expires in 2 days...")
    ->Show(toast =>
    {
        toast->ExpirationTime = DateTime::Now->AddDays(2);
    });
```

Provide a primary key for your toast

If you want to programmatically remove or replace the notification you send, you need to use the Tag property (and optionally the Group property) to provide a primary key for your notification. Then, you can use this primary key in the future to remove or replace the notification.

To see more details on replacing/removing already delivered toast notifications, please see Quickstart: Managing toast notifications in action center (XAML).

Tag and Group combined act as a composite primary key. Group is the more generic identifier, where you can assign groups like "wallPosts", "messages", "friendRequests", etc. And then Tag should uniquely identify the notification itself from within the group. By using a generic group, you can then remove all notifications from that group by using the RemoveGroup API.

C++

```
// Create toast content and show the toast!
(ref new ToastContentBuilder())
    ->AddText("New post on your wall!")
    ->Show(toast =>
    {
        toast.Tag = "18365";
```

```
        toast.Group = "wallPosts";
    });
```

Clear your notifications

Apps are responsible for removing and clearing their own notifications. When your app is launched, we do NOT automatically clear your notifications.

Windows will only automatically remove a notification if the user explicitly clicks the notification.

Here's an example of what a messaging app should do...

1. User receives multiple toasts about new messages in a conversation
2. User taps one of those toasts to open the conversation
3. The app opens the conversation and then clears all toasts for that conversation (by using RemoveGroup on the app-supplied group for that conversation)
4. User's Action Center now properly reflects the notification state, since there are no stale notifications for that conversation left in Action Center.

To learn about clearing all notifications or removing specific notifications, see Quickstart: Managing toast notifications in action center (XAML).

C++

```
ToastNotificationManagerCompat::History->Clear();
```

Send a local toast notification from a WRL C++ desktop app

Article • 10/27/2022

Packaged and unpackaged desktop apps can send interactive toast notifications just like Universal Windows platform (UWP) apps can. That includes packaged apps (see Create a new project for a packaged WinUI 3 desktop app); packaged apps with external location (see Grant package identity by packaging with external location); and unpackaged apps (see Create a new project for an unpackaged WinUI 3 desktop app).

However, for an unpackaged desktop app, there are a few special steps. That's due to the different activation schemes, and the lack of package identity at runtime.

> **Important**
>
> If you're writing a UWP app, please see the **UWP documentation**. For other desktop languages, please see **Desktop C#**.

Step 1: Enable the Windows SDK

If you haven't enabled the Windows SDK for your app, then you must do that first. There are a few key steps.

1. Add `runtimeobject.lib` to **Additional Dependencies**.
2. Target the Windows SDK.

Right click your project and select **Properties**.

In the top **Configuration** menu, select **All Configurations** so that the following change is applied to both Debug and Release.

Under **Linker -> Input**, add `runtimeobject.lib` to the **Additional Dependencies**.

Then under **General**, make sure that the **Windows SDK Version** is set to version 10.0 or later.

Step 2: Copy compat library code

Copy the DesktopNotificationManagerCompat.h and DesktopNotificationManagerCompat.cpp file from GitHub into your project. The

compat library abstracts much of the complexity of desktop notifications. The following instructions require the compat library.

If you're using precompiled headers, make sure to `#include "stdafx.h"` as the first line of the DesktopNotificationManagerCompat.cpp file.

Step 3: Include the header files and namespaces

Include the compat library header file, and the header files and namespaces related to using the Windows toast APIs.

C++

```
#include "DesktopNotificationManagerCompat.h"
#include <NotificationActivationCallback.h>
#include <windows.ui.notifications.h>

using namespace ABI::Windows::Data::Xml::Dom;
using namespace ABI::Windows::UI::Notifications;
using namespace Microsoft::WRL;
```

Step 4: Implement the activator

You must implement a handler for toast activation, so that when the user clicks on your toast, your app can do something. This is required for your toast to persist in Action Center (since the toast could be clicked days later when your app is closed). This class can be placed anywhere in your project.

Implement the **INotificationActivationCallback** interface as seen below, including a UUID, and also call **CoCreatableClass** to flag your class as COM creatable. For your UUID, create a unique GUID using one of the many online GUID generators. This GUID CLSID (class identifier) is how Action Center knows what class to COM activate.

C++

```
// The UUID CLSID must be unique to your app. Create a new GUID if copying
this code.
class DECLSPEC_UUID("replaced-with-your-guid-C173E6ADF0C3")
NotificationActivator WrlSealed WrlFinal
    : public RuntimeClass<RuntimeClassFlags<ClassicCom>,
INotificationActivationCallback>
{
public:
```

```
    virtual HRESULT STDMETHODCALLTYPE Activate(
        _In_ LPCWSTR appUserModelId,
        _In_ LPCWSTR invokedArgs,
        _In_reads_(dataCount) const NOTIFICATION_USER_INPUT_DATA* data,
        ULONG dataCount) override
    {
        // TODO: Handle activation
    }
};

// Flag class as COM creatable
CoCreatableClass(NotificationActivator);
```

Step 5: Register with notification platform

Then, you must register with the notification platform. There are different steps depending on whether your app is packaged or unpackaged. If you support both, then you must perform both sets of steps (however, there's no need to fork your code since our library handles that for you).

Packaged

If your app is packaged (see Create a new project for a packaged WinUI 3 desktop app) or packaged with external location (see Grant package identity by packaging with external location), or if you support both, then in your **Package.appxmanifest** add:

1. Declaration for **xmlns:com**
2. Declaration for **xmlns:desktop**
3. In the **IgnorableNamespaces** attribute, **com** and **desktop**
4. **com:Extension** for the COM activator using the GUID from step #4. Be sure to include the `Arguments="-ToastActivated"` so that you know your launch was from a toast
5. **desktop:Extension** for **windows.toastNotificationActivation** to declare your toast activator CLSID (the GUID from step #4).

Package.appxmanifest

XML

```
<Package
  ...
  xmlns:com="http://schemas.microsoft.com/appx/manifest/com/windows10"

xmlns:desktop="http://schemas.microsoft.com/appx/manifest/desktop/windows10"
  IgnorableNamespaces="... com desktop">
```

```
  ...
  <Applications>
    <Application>
      ...
      <Extensions>

        <!--Register COM CLSID LocalServer32 registry key-->
        <com:Extension Category="windows.comServer">
          <com:ComServer>
            <com:ExeServer Executable="YourProject\YourProject.exe"
Arguments="-ToastActivated" DisplayName="Toast activator">
              <com:Class Id="replaced-with-your-guid-C173E6ADF0C3"
DisplayName="Toast activator"/>
            </com:ExeServer>
          </com:ComServer>
        </com:Extension>

        <!--Specify which CLSID to activate when toast clicked-->
        <desktop:Extension Category="windows.toastNotificationActivation">
          <desktop:ToastNotificationActivation
ToastActivatorCLSID="replaced-with-your-guid-C173E6ADF0C3" />
        </desktop:Extension>

      </Extensions>
    </Application>
  </Applications>
 </Package>
```

Unpackaged

If your app is unpackaged (see Create a new project for an unpackaged WinUI 3 desktop app), or if you support both, then you have to declare your Application User Model ID (AUMID) and toast activator CLSID (the GUID from step #4) on your app's shortcut in Start.

Pick a unique AUMID that will identify your app. This is typically in the form of [CompanyName].[AppName]. But you want to ensure that it's unique across all apps (so feel free to add some digits at the end).

Step 5.1: WiX Installer

If you're using WiX for your installer, edit the **Product.wxs** file to add the two shortcut properties to your Start menu shortcut as seen below. Be sure that your GUID from step #4 is enclosed in `{}` as seen below.

Product.wxs

XML

```
<Shortcut Id="ApplicationStartMenuShortcut" Name="Wix Sample"
Description="Wix Sample" Target="[INSTALLFOLDER]WixSample.exe"
WorkingDirectory="INSTALLFOLDER">

    <!--AUMID-->
    <ShortcutProperty Key="System.AppUserModel.ID"
Value="YourCompany.YourApp"/>

    <!--COM CLSID-->
    <ShortcutProperty Key="System.AppUserModel.ToastActivatorCLSID" Value="
{replaced-with-your-guid-C173E6ADF0C3}"/>

</Shortcut>
```

> **ⓘ Important**
>
> In order to actually use notifications, you must install your app through the installer once before debugging normally, so that the Start shortcut with your AUMID and CLSID is present. After the Start shortcut is present, you can debug using F5 from Visual Studio.

Step 5.2: Register AUMID and COM server

Then, regardless of your installer, in your app's startup code (before calling any notification APIs), call the **RegisterAumidAndComServer** method, specifying your notification activator class from step #4 and your AUMID used above.

C++

```
// Register AUMID and COM server (for a packaged app, this is a no-
operation)
hr =
DesktopNotificationManagerCompat::RegisterAumidAndComServer(L"YourCompany.Yo
urApp", __uuidof(NotificationActivator));
```

If your app supports both packaged and unpackaged deployment, then feel free to call this method regardless. If you're running packaged (that is, with package identity at runtime), then this method will simply return immediately. There's no need to fork your code.

This method allows you to call the compat APIs to send and manage notifications without having to constantly provide your AUMID. And it inserts the LocalServer32 registry key for the COM server.

Step 6: Register COM activator

For both packaged and unpackaged apps, you must register your notification activator type, so that you can handle toast activations.

In your app's startup code, call the following **RegisterActivator** method. This must be called in order for you to receive any toast activations.

C++

```
// Register activator type
hr = DesktopNotificationManagerCompat::RegisterActivator();
```

Step 7: Send a notification

Sending a notification is identical to UWP apps, except that you'll use **DesktopNotificationManagerCompat** to create a **ToastNotifier**. The compat library automatically handles the difference between packaged and unpackaged apps, so you don't need to fork your code. For an unpackaged app, the compat library caches the AUMID that you provided when you called **RegisterAumidAndComServer** so that you don't need to worry about when to provide or not provide the AUMID.

Make sure you use the **ToastGeneric** binding as seen below, since the legacy Windows 8.1 toast notification templates won't activate the COM notification activator that you created in step #4.

> **ⓘ Important**
>
> Http images are supported only in packaged apps that have the internet capability in their manifest. Unpackaged apps don't support http images; you must download the image to your local app data, and reference it locally.

C++

```
// Construct XML
ComPtr<IXmlDocument> doc;
hr = DesktopNotificationManagerCompat::CreateXmlDocumentFromString(
    L"<toast><visual><binding template='ToastGeneric'><text>Hello
world</text></binding></visual></toast>",
    &doc);
if (SUCCEEDED(hr))
{
    // See full code sample to learn how to inject dynamic text, buttons,
and more
```

```
    // Create the notifier
    // Desktop apps must use the compat method to create the notifier.
    ComPtr<IToastNotifier> notifier;
    hr = DesktopNotificationManagerCompat::CreateToastNotifier(&notifier);
    if (SUCCEEDED(hr))
    {
        // Create the notification itself (using helper method from compat
library)
        ComPtr<IToastNotification> toast;
        hr =
DesktopNotificationManagerCompat::CreateToastNotification(doc.Get(),
&toast);
        if (SUCCEEDED(hr))
        {
            // And show it!
            hr = notifier->Show(toast.Get());
        }
    }
}
```

> **ⓘ Important**
>
> Desktop apps can't use legacy toast templates (such as ToastText02). Activation of the legacy templates will fail when the COM CLSID is specified. You must use the Windows ToastGeneric templates, as seen above.

Step 8: Handling activation

When the user clicks on your toast, or buttons in the toast, the **Activate** method of your **NotificationActivator** class is invoked.

Inside the Activate method, you can parse the args that you specified in the toast and obtain the user input that the user typed or selected, and then activate your app accordingly.

> **ⓘ Note**
>
> The **Activate** method is called on a separate thread from your main thread.

C++

```
// The GUID must be unique to your app. Create a new GUID if copying this
code.
class DECLSPEC_UUID("replaced-with-your-guid-C173E6ADF0C3")
```

```
NotificationActivator WrlSealed WrlFinal
    : public RuntimeClass<RuntimeClassFlags<ClassicCom>,
INotificationActivationCallback>
{
public:
    virtual HRESULT STDMETHODCALLTYPE Activate(
        _In_ LPCWSTR appUserModelId,
        _In_ LPCWSTR invokedArgs,
        _In_reads_(dataCount) const NOTIFICATION_USER_INPUT_DATA* data,
        ULONG dataCount) override
    {
        std::wstring arguments(invokedArgs);
        HRESULT hr = S_OK;

        // Background: Quick reply to the conversation
        if (arguments.find(L"action=reply") == 0)
        {
            // Get the response user typed.
            // We know this is first and only user input since our toasts
only have one input
            LPCWSTR response = data[0].Value;

            hr = DesktopToastsApp::SendResponse(response);
        }

        else
        {
            // The remaining scenarios are foreground activations,
            // so we first make sure we have a window open and in foreground
            hr = DesktopToastsApp::GetInstance()->OpenWindowIfNeeded();
            if (SUCCEEDED(hr))
            {
                // Open the image
                if (arguments.find(L"action=viewImage") == 0)
                {
                    hr = DesktopToastsApp::GetInstance()->OpenImage();
                }

                // Open the app itself
                // User might have clicked on app title in Action Center
which launches with empty args
                else
                {
                    // Nothing to do, already launched
                }
            }
        }

        if (FAILED(hr))
        {
            // Log failed HRESULT
        }

        return S_OK;
    }
```

```
    ~NotificationActivator()
    {
        // If we don't have window open
        if (!DesktopToastsApp::GetInstance()->HasWindow())
        {
            // Exit (this is for background activation scenarios)
            exit(0);
        }
    }
};

// Flag class as COM creatable
CoCreatableClass(NotificationActivator);
```

To properly support being launched while your app is closed, in your WinMain function, you'll want to determine whether you're being launched from a toast or not. If launched from a toast, there will be a launch arg of "-ToastActivated". When you see this, you should stop performing any normal launch activation code, and allow your **NotificationActivator** to handle launching windows if needed.

C++

```
// Main function
int WINAPI wWinMain(_In_ HINSTANCE hInstance, _In_opt_ HINSTANCE, _In_
LPWSTR cmdLineArgs, _In_ int)
{
    RoInitializeWrapper winRtInitializer(RO_INIT_MULTITHREADED);

    HRESULT hr = winRtInitializer;
    if (SUCCEEDED(hr))
    {
        // Register AUMID and COM server (for a packaged app, this is a no-
operation)
        hr =
DesktopNotificationManagerCompat::RegisterAumidAndComServer(L"WindowsNotific
ations.DesktopToastsCpp", __uuidof(NotificationActivator));
        if (SUCCEEDED(hr))
        {
            // Register activator type
            hr = DesktopNotificationManagerCompat::RegisterActivator();
            if (SUCCEEDED(hr))
            {
                DesktopToastsApp app;
                app.SetHInstance(hInstance);

                std::wstring cmdLineArgsStr(cmdLineArgs);

                // If launched from toast
                if (cmdLineArgsStr.find(TOAST_ACTIVATED_LAUNCH_ARG) !=
std::string::npos)
                {
```

```
                    // Let our NotificationActivator handle activation
                }

                else
                {
                    // Otherwise launch like normal
                    app.Initialize(hInstance);
                }

                app.RunMessageLoop();
            }
        }
    }

    return SUCCEEDED(hr);
}
```

Activation sequence of events

The activation sequence is the following...

If your app is already running:

1. **Activate** in your **NotificationActivator** is called

If your app is not running:

1. Your app is EXE launched, you get a command line args of "-ToastActivated"
2. **Activate** in your **NotificationActivator** is called

Foreground vs background activation

For desktop apps, foreground and background activation is handled identically—your COM activator is called. It's up to your app's code to decide whether to show a window or to simply perform some work and then exit. Therefore, specifying an **activationType** of **background** in your toast content doesn't change the behavior.

Step 9: Remove and manage notifications

Removing and managing notifications is identical to UWP apps. However, we recommend you use our compat library to obtain a **DesktopNotificationHistoryCompat** so you don't have to worry about providing the AUMID for a desktop app.

```
C++
```

```
std::unique_ptr<DesktopNotificationHistoryCompat> history;
auto hr = DesktopNotificationManagerCompat::get_History(&history);
if (SUCCEEDED(hr))
{
    // Remove a specific toast
    hr = history->Remove(L"Message2");

    // Clear all toasts
    hr = history->Clear();
}
```

Step 10: Deploying and debugging

To deploy and debug your packaged app, see Run, debug, and test a packaged desktop app.

To deploy and debug your desktop app, you must install your app through the installer once before debugging normally, so that the Start shortcut with your AUMID and CLSID is present. After the Start shortcut is present, you can debug using F5 from Visual Studio.

If your notifications simply fail to appear in your desktop app (and no exceptions are thrown), that likely means the Start shortcut isn't present (install your app via the installer), or the AUMID you used in code doesn't match the AUMID in your Start shortcut.

If your notifications appear but aren't persisted in Action Center (disappearing after the popup is dismissed), that means you haven't implemented the COM activator correctly.

If you've installed both your packaged and unpackaged desktop app, note that the packaged app will supersede the unpackaged app when handling toast activations. That means that toasts from the unpackaged app will launch the packaged app when clicked. Uninstalling the packaged app will revert activations back to the unpackaged app.

If you receive `HRESULT 0x800401f0 CoInitialize has not been called.`, be sure to call `CoInitialize(nullptr)` in your app before calling the APIs.

If you receive `HRESULT 0x8000000e A method was called at an unexpected time.` while calling the Compat APIs, that likely means you failed to call the required Register methods (or if a packaged app, you're not currently running your app under the packaged context).

If you get numerous `unresolved external symbol` compilation errors, you likely forgot to add `runtimeobject.lib` to the **Additional Dependencies** in step #1 (or you only added it to the Debug configuration and not Release configuration).

Handling older versions of Windows

If you support Windows 8.1 or lower, you'll want to check at runtime whether you're running on Windows before calling any **DesktopNotificationManagerCompat** APIs or sending any ToastGeneric toasts.

Windows 8 introduced toast notifications, but used the legacy toast templates, like ToastText01. Activation was handled by the in-memory **Activated** event on the **ToastNotification** class since toasts were only brief popups that weren't persisted. Windows 10 introduced interactive ToastGeneric toasts, and also introduced Action Center where notifications are persisted for multiple days. The introduction of Action Center required the introduction of a COM activator, so that your toast can be activated days after you created it.

Expand table

OS	ToastGeneric	COM activator	Legacy toast templates
Windows 10 and later	Supported	Supported	Supported (but won't activate COM server)
Windows 8.1 / 8	N/A	N/A	Supported
Windows 7 and lower	N/A	N/A	N/A

To check whether you're running on Windows 10 or later, include the `<VersionHelpers.h>` header, and check the **IsWindows10OrGreater** method. If that returns `true`, then continue calling all the methods described in this documentation.

C++

```
#include <VersionHelpers.h>

if (IsWindows10OrGreater())
{
    // Running on Windows 10 or later, continue with sending toasts!
}
```

Known issues

FIXED: App doesn't become focused after clicking toast: In builds 15063 and earlier, foreground rights weren't being transferred to your application when we activated the

COM server. Therefore, your app would simply flash when you tried to move it to the foreground. There was no workaround for this issue. We fixed this in builds 16299 or later.

Send a local toast notification from other types of unpackaged apps

Article • 10/24/2022

This topic is for you if you're developing an unpackaged app that's not C# or C++.

That is, if you're *not* developing a packaged app (see Create a new project for a packaged WinUI 3 desktop app), and you're not developing a packaged app with external location (see Grant package identity by packaging with external location), and your app isn't C# or C++.

A toast notification is a message that an app can construct and deliver to the user while the user is not currently using your app. This quickstart walks you through the steps to create, deliver, and display a Windows toast notification. These quickstart uses local notifications, which are the simplest notification to implement.

> **ⓘ Important**
>
> If you're writing a C# app, then please see the **C# documentation**. If you're writing a C++ app, the please see the **C++ UWP** or **C++ WRL** documentation.

Step 1: Register your app in the registry

You first need to register your app's information in the registry, including a unique AUMID that identifies your app, your app's display name, your icon, and a COM activator's GUID.

XML

```
<registryKey keyName="HKEY_LOCAL_MACHINE\Software\Classes\AppUserModelId\
<YOUR_AUMID>">
    <registryValue
        name="DisplayName"
        value="My App"
        valueType="REG_EXPAND_SZ" />
    <registryValue
        name="IconUri"
        value="C:\icon.png"
        valueType="REG_EXPAND_SZ" />
    <registryValue
        name="IconBackgroundColor"
        value="AARRGGBB"
        valueType="REG_SZ" />
```

```
    <registryValue
        name="CustomActivator"
        value="{YOUR COM ACTIVATOR GUID HERE}"
        valueType="REG_SZ" />
</registryKey>
```

Step 2: Set up your COM activator

Notifications can be clicked at any point in time, even when your app isn't running. Thus, notification activation is handled through a COM activator. Your COM class must implement the `INotificationActivationCallback` interface. The GUID for your COM class must match the GUID you specified in the registry CustomActivator value.

C++

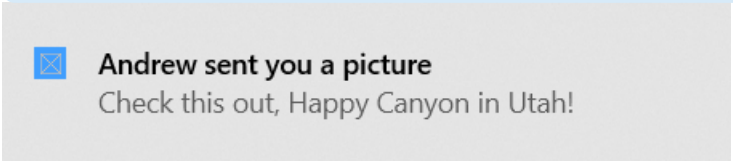
```
struct callback : winrt::implements<callback,
INotificationActivationCallback>
{
    HRESULT __stdcall Activate(
        LPCWSTR app,
        LPCWSTR args,
        [[maybe_unused]] NOTIFICATION_USER_INPUT_DATA const* data,
        [[maybe_unused]] ULONG count) noexcept final
    {
        try
        {
            std::wcout << this_app_name << L" has been called back from a
notification." << std::endl;
            std::wcout << L"Value of the 'app' parameter is '" << app <<
L"'." << std::endl;
            std::wcout << L"Value of the 'args' parameter is '" << args <<
L"'." << std::endl;
            return S_OK;
        }
        catch (...)
        {
            return winrt::to_hresult();
        }
    }
};
```

Step 3: Send a toast

In Windows 10, your toast notification content is described using an adaptive language that allows great flexibility with how your notification looks. See the toast content documentation for more information.

We'll start with a simple text-based notification. Construct the notification content (using the Notifications library), and show the notification!

> **ⓘ Important**
>
> You must use your AUMID from earlier when sending the notification so that the notification appears from your app.



C++

```
// Construct the toast template
XmlDocument doc;
doc.LoadXml(L"<toast>\
    <visual>\
        <binding template=\"ToastGeneric\">\
            <text></text>\
            <text></text>\
        </binding>\
    </visual>\
</toast>");

// Populate with text and values
doc.SelectSingleNode(L"//text[1]").InnerText(L"Andrew sent you a picture");
doc.SelectSingleNode(L"//text[2]").InnerText(L"Check this out, The
Enchantments in Washington!");

// Construct the notification
ToastNotification notif{ doc };

// And send it! Use the AUMID you specified earlier.
ToastNotificationManager::CreateToastNotifier(L"MyPublisher.MyApp").Show(not
if);
```

Step 4: Handling activation

Your COM activator will be activated when your notification is clicked.

More details

AUMID restrictions

The AUMID should be at most 129 characters long. If the AUMID is more than 129 characters long, scheduled toast notifications won't work - you'll get the following exception when adding a scheduled notification: *The data area passed to a system call is too small. (0x8007007A)*.

Activating toast notifications from desktop apps

Article • 03/03/2025

Packaged and unpackaged Win32 apps can send interactive toast notifications just like UWP apps can. That includes packaged apps (see Create a new project for a packaged WinUI 3 desktop app); packaged apps with external location (see Grant package identity by packaging with external location); and unpackaged apps (see Create a new project for an unpackaged WinUI 3 desktop app).

However, for an unpackaged Win32 app there are a few special steps. That's due to the different activation schemes, and the lack of package identity at runtime.

In this topic, we list out the options you have for sending a toast notification on Windows 10. Every option fully supports...

- Persisting in Action Center
- Being activatable from both the popup and inside Action Center
- Being activatable while your EXE isn't running

All options

The table below illustrates your options for supporting toasts within your desktop app, and the corresponding supported features. You can use the table to select the best option for your scenario.

Expand table

Option	Visuals	Actions	Inputs	Activates in-process
COM activator	**Supported**	**Supported**	**Supported**	**Supported**
No COM / Stub CLSID	**Supported**	**Supported**	Not supported	Not supported

Preferred option - COM activator

This is the preferred option that works for desktop apps, and supports all notification features. Don't be afraid of the "COM activator"; we have a library for C# and C++ apps

that makes this very straightforward, even if you've never written a COM server before.

Expand table

Visuals	Actions	Inputs	Activates in-process
Supported	Supported	Supported	Supported

With the COM activator option, you can use the following notification templates and activation types in your app.

Expand table

Template and activation type	Packaged	Unpackaged
ToastGeneric Foreground	**Supported**	**Supported**
ToastGeneric Background	**Supported**	**Supported**
ToastGeneric Protocol	**Supported**	**Supported**
Legacy templates	**Supported**	Not supported

> **Note**
>
> If you add the COM activator to your existing packaged app, then Foreground/Background and Legacy notification activations will activate your COM activator instead of your command line.

To learn how to use this option, see Send a local toast notification from desktop C# apps or Send a local toast notification from Win32 C++ WRL apps.

Alternative option - No COM / Stub CLSID

This is an alternative option if you can't implement a COM activator. However, you'll sacrifice a few features, such as input support (text boxes on toasts) and activating in-process.

Expand table

Visuals	Actions	Inputs	Activates in-process
Supported	**Supported**	Not supported	Not supported

With this option, if you support desktop, then you're much more limited in the notification templates and activation types that you can use, as seen below.

Expand table

Template and activation type	Packaged	Unpackaged
ToastGeneric Foreground	**Supported**	Not supported
ToastGeneric Background	**Supported**	Not supported
ToastGeneric Protocol	**Supported**	**Supported**
Legacy templates	**Supported**	Not supported

For packaged apps, just send toast notifications like a UWP app would. When the user clicks on your toast, your app will be command-line launched with the launch args that you specified in the toast.

For unpackaged apps, set up the AUMID so that you can send toasts, and then also specify a CLSID on your shortcut. That can be any random GUID. Don't add the COM server/activator. You're adding a "stub" COM CLSID, which will cause Action Center to persist the notification. Note that you can use only protocol activation toasts, because the stub CLSID will break activation of any other toast activations. Therefore, you have to update your app to support protocol activation, and have the toast's protocol activate your own app.

App notification content

Article • 04/12/2024

App notifications are flexible notifications with text, images, and buttons/inputs. This article describes the UI elements that can be used in an app notification and provides code examples for generating the XML format for an app notification.

> **Note**
>
> The term "toast notification" is being replaced with "app notification". These terms both refer to the same feature of Windows, but over time we will phase out the use of "toast notification" in the documentation.

Getting started

App notifications are defined with an XML payload which is defined by the App notification schema. Currently, there are three ways of generating the XML payload fo an app notification. The code examples in this article demonstrate all three methods:

- The Microsoft.Windows.AppNotifications.Builder APIs - Introduced in Windows App SDK 1.2, this namespace provides APIs that allow you to easily build the XML payload for a notification programmatically without having to worry about the specifics of the XML format. Code examples using these APIs are in the tabs labeled "Windows App SDK".
- The `Microsoft.Toolkit.Uwp.Notifications` builder syntax - These APIs are part of the UWP Community Toolkit and provides support for UWP apps. Although these APIs can also be used for Windows App SDK apps, and continue to be supported, we recommend that new implementations use the **Microsoft.Windows.AppNotifications.Builder** APIs. To use Community Toolkit APIs, add the UWP Community Toolkit Notifications nuget package to your project. The C# samples provided in this article use version 7.0.0 of the NuGet package. Code examples using these APIs are in the tabs labeled "Windows Community Toolkit".
- Raw XML - If you prefer, you can create your own custom code to generate XML strings in the required format. The raw XML examples are in the tabs labeled "XML".

Install Notifications Visualizer. This free Windows app helps you design interactive app notifications by providing an instant visual preview of your toast as you edit it, similar to

Visual Studio's XAML editor/design view. See Notifications Visualizer for more information, or download Notifications Visualizer from the Store.

This article only covers creating the app notification content. For information on sending a notification after you have generated the XML payload, see Send a local app notification.

App notification structure

Some important, high-level components of an app notification XML payload include:

- **toast**: The **launch** attribute of this element defines what arguments will be passed back to your app when the user clicks your toast, allowing you to deep link into the correct content that the toast was displaying. To learn more, see Send a local app notification.
- **visual**: This element represents visual portion of the toast, including the generic binding that contains text and images.
- **actions**: This element represents interactive portion of the toast, including inputs and actions.
- **audio**: This element specifies the audio played when the toast is shown to the user.

Windows App SDK

C#

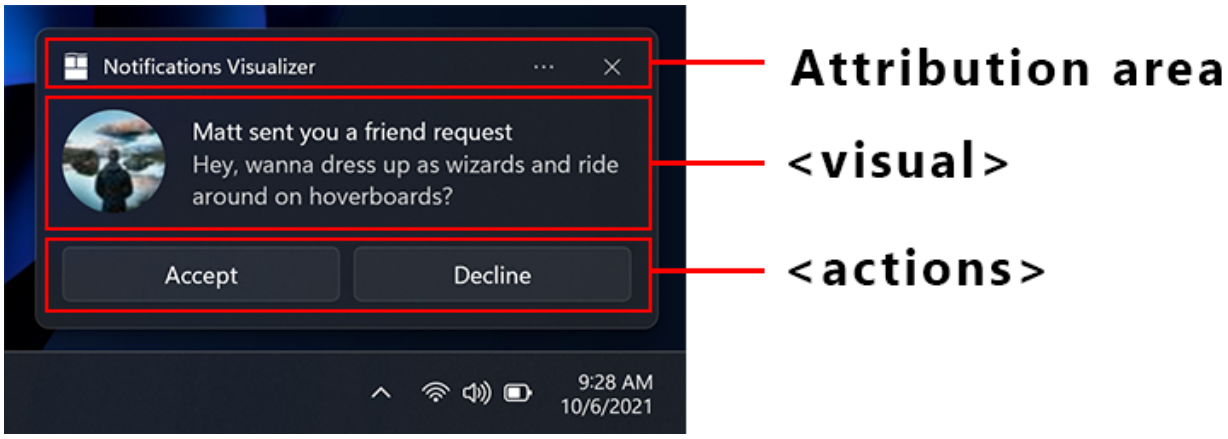
```
var builder = new AppNotificationBuilder()
    .AddArgument("conversationId", "9813")

    .AddText("Some text")

    .AddButton(new AppNotificationButton("Archive")
        .AddArgument("action", "archive"))

    .SetAudioUri(new Uri("ms-appx:///Sound.mp3"));
```

Here is a visual representation of the app notification's content:



Attribution area

The attribution area is at the top of the app notification. Starting with Windows 11, your app's name and icon are displayed in this area. The attribution area also includes a close button that allows the user to quickly dismiss the notification and an ellipses menu that allows the user to quickly disable notifications for your app or go to the Windows Settings page for your app's notifications. The attribution area is configured by the shell and can't be overridden in the toast XML payload, although your app can add items to the attribution area context menu. For more information see Context menu actions.

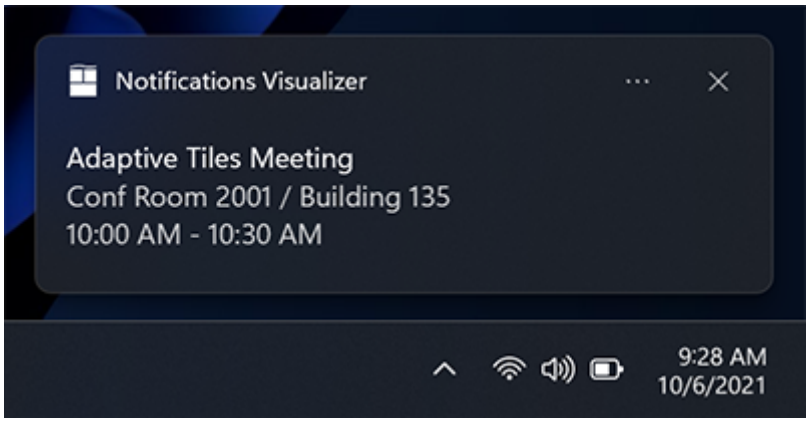
Visual

Each app notification must specify a **visual** element, where you must provide a generic toast binding and which can contain text and images. These elements will be rendered on various Windows devices, including desktop, phones, tablets, and Xbox.

For all attributes supported in the **visual** section and its child elements, see App notification schema.

Text elements

Each app notification must have at least one text element, and can contain two additional text elements, all of type **AdaptiveText**.



Since the Windows 10 Anniversary Update, you can control how many lines of text are displayed by using the **HintMaxLines** property on the text. The default (and maximum) is up to 2 lines of text for the title, and up to 4 lines (combined) for the two additional description elements (the second and third **AdaptiveText**).

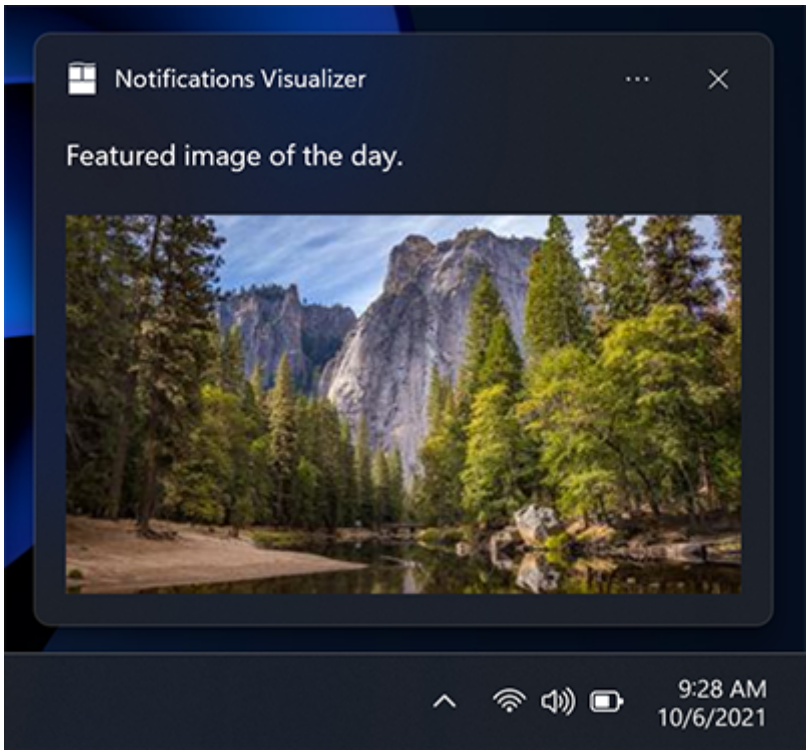
Windows App SDK

C#

```
var builder = new AppNotificationBuilder()
    .AddArgument("conversationId", 9813)
    .AddText("Adaptive Tiles Meeting", new
AppNotificationTextProperties().SetMaxLines(1))
    .AddText("Conf Room 2001 / Building 135")
    .AddText("10:00 AM - 10:30 AM");
```

Inline image

By default, images are displayed inline, after any text elements, filling the full width of the visual area.



Windows App SDK

C#

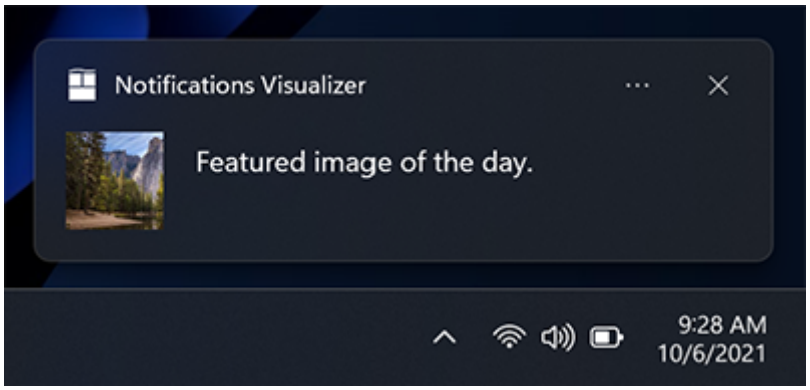
```
var builder = new AppNotificationBuilder()
    .AddText("Featured image of the day.")
    .SetInlineImage(new Uri("ms-appx:///Images/InlineImage.png"));

AppNotificationManager.Default.Show(builder.BuildNotification());
```

App logo override

Specifying a **placement** value of "appLogoOverride" will cause the image to be displayed in a square on the left side of the visual area. The name of this property reflects the behavior in previous versions of Windows, where the image would replace the default app logo image. In Windows 11, the app logo is displayed in the attribution area, so it is not overridden by the **appLogoOverride** image placement.

Image dimensions are 48x48 pixels at 100% scaling. We generally recommend providing a version each icon asset for each scale factor: 100%, 125%, 150%, 200%, and 400%.



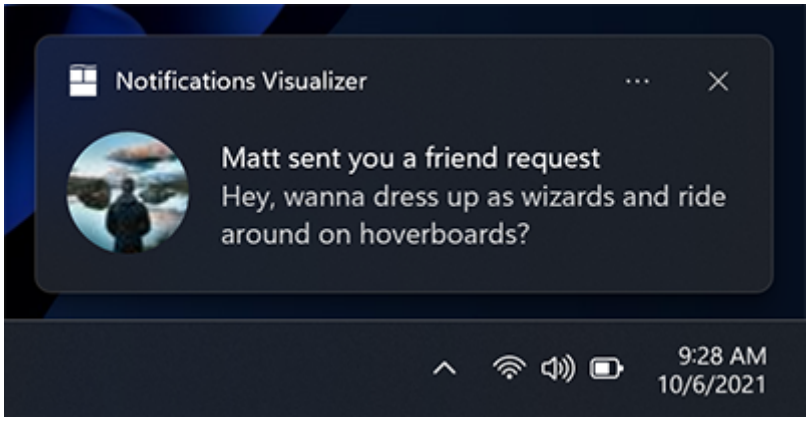
Windows App SDK

C#

```
var builder = new AppNotificationBuilder()
    .AddText("Featured image of the day.")
    .SetAppLogoOverride(new Uri("ms-appx:///Images/AppLogo.png"));
```

Hint crop

Microsoft style guidelines recommend representing profile pictures with a circular image to provide a consistent representation of people across apps and the shell. Set the **HintCrop** property to **Circle** to render the image with a circular crop.



Windows App SDK

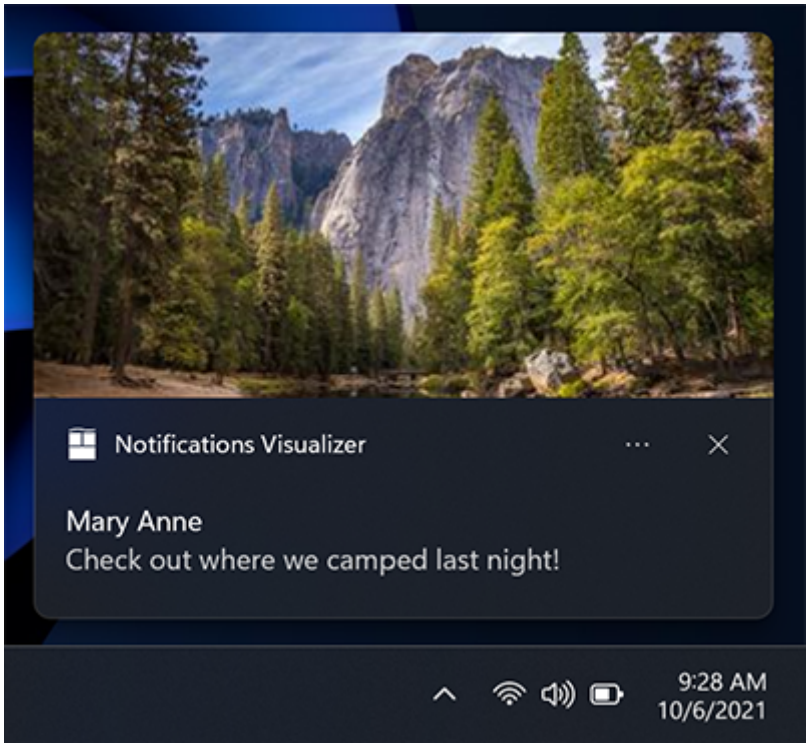
C#

```
var builder = new AppNotificationBuilder()
    .AddText("Matt sent you a friend request")
    .AddText("Hey, wanna dress up as wizards and ride around on
hoverboards?")
```

```
    .SetAppLogoOverride(new Uri("ms-appx:///Images/Profile.png"),
AppNotificationImageCrop.Circle);
```

Hero image

New in Anniversary Update: App notifications can display a hero image, which is a featured ToastGenericHeroImage displayed prominently within the toast banner and while inside Notification Center. Image dimensions are 364x180 pixels at 100% scaling.



Windows App SDK

C#

```
var builder = new AppNotificationBuilder()
    .AddText("Marry Anne")
    .AddText("Check out where we camped last night!")
    .SetHeroImage(new Uri("ms-appx:///Images/HeroImage.png"));
```

Image size restrictions

The images you use in your toast notification can be sourced from...

- http://
- ms-appx:///

- ms-appdata:///

For http and https remote web images, there are limits on the file size of each individual image. In the Fall Creators Update (16299), we increased the limit to be 3 MB on normal connections and 1 MB on metered connections. Before that, images were always limited to 200 KB.

Expand table

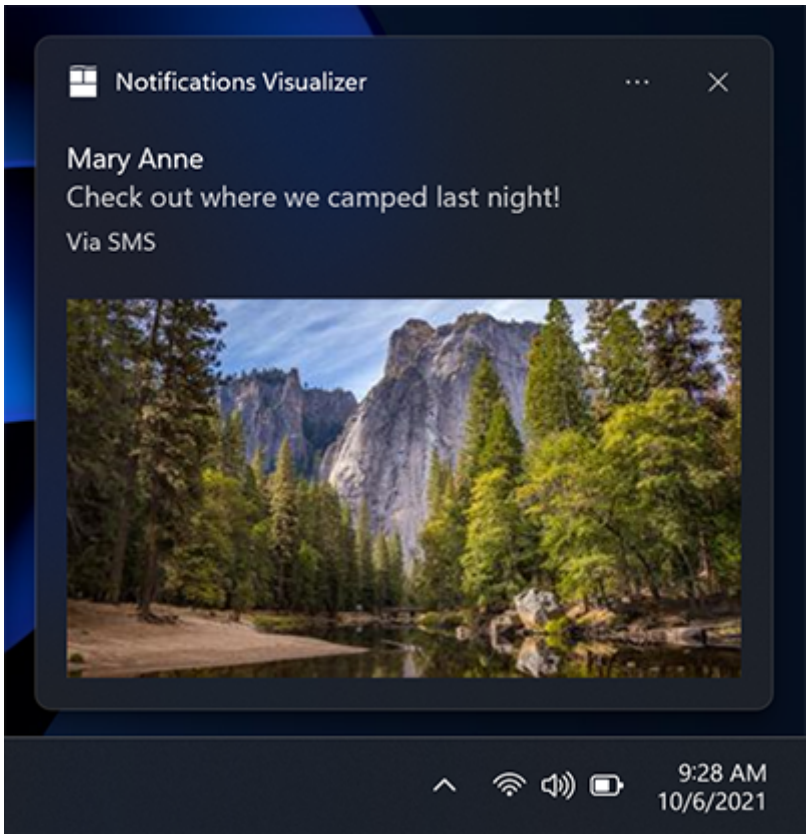
Normal connection	Metered connection	Before Fall Creators Update
3 MB	1 MB	200 KB

If an image exceeds the file size, or fails to download, or times out, the image will be dropped and the rest of the notification will be displayed.

Attribution text

New in Anniversary Update: If you need to reference the source of your content, you can use attribution text. This text is always displayed below any text elements, but above inline images. The text uses a slightly smaller size than standard text elements to help to distinguish from regular text elements.

On older versions of Windows that don't support attribution text, the text will simply be displayed as another text element (assuming you don't already have the maximum of three text elements).



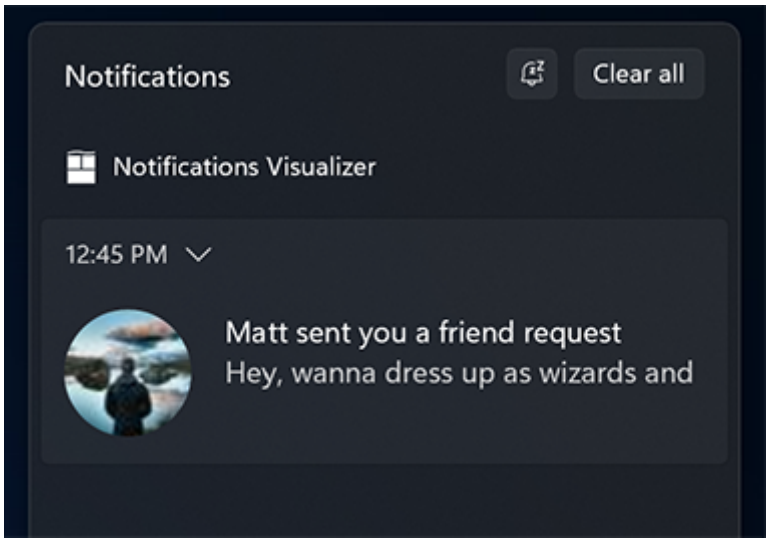
Windows App SDK

C#

```
var builder = new AppNotificationBuilder()
    .AddText("Marry Anne")
    .AddText("Check out where we camped last night!")
    .SetAttributionText("via SMS");
    .SetHeroImage(new Uri("ms-appx:///Images/HeroImage.png"));
```

Custom timestamp

New in Creators Update: You can now override the system-provided timestamp with your own timestamp that accurately represents when the message/information/content was generated. This timestamp is visible within Notification Center.



To learn more about using a custom timestamp, please see custom timestamps on toasts.

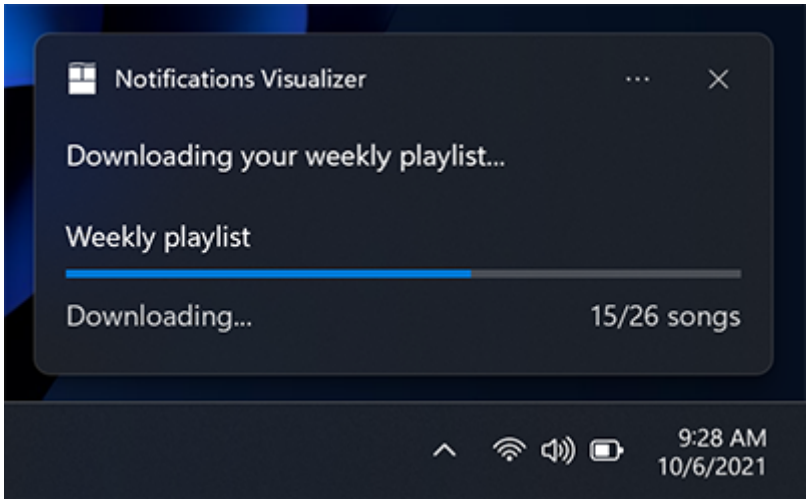
Windows App SDK

C#

```
var builder = new AppNotificationBuilder()
    .AddText("Matt sent you a friend request")
    .AddText("Hey, wanna dress up as wizards and ride around on
hoverboards?")
    .SetTimeStamp(new DateTime(2017, 04, 15, 19, 45, 00,
DateTimeKind.Utc));
```

Progress bar

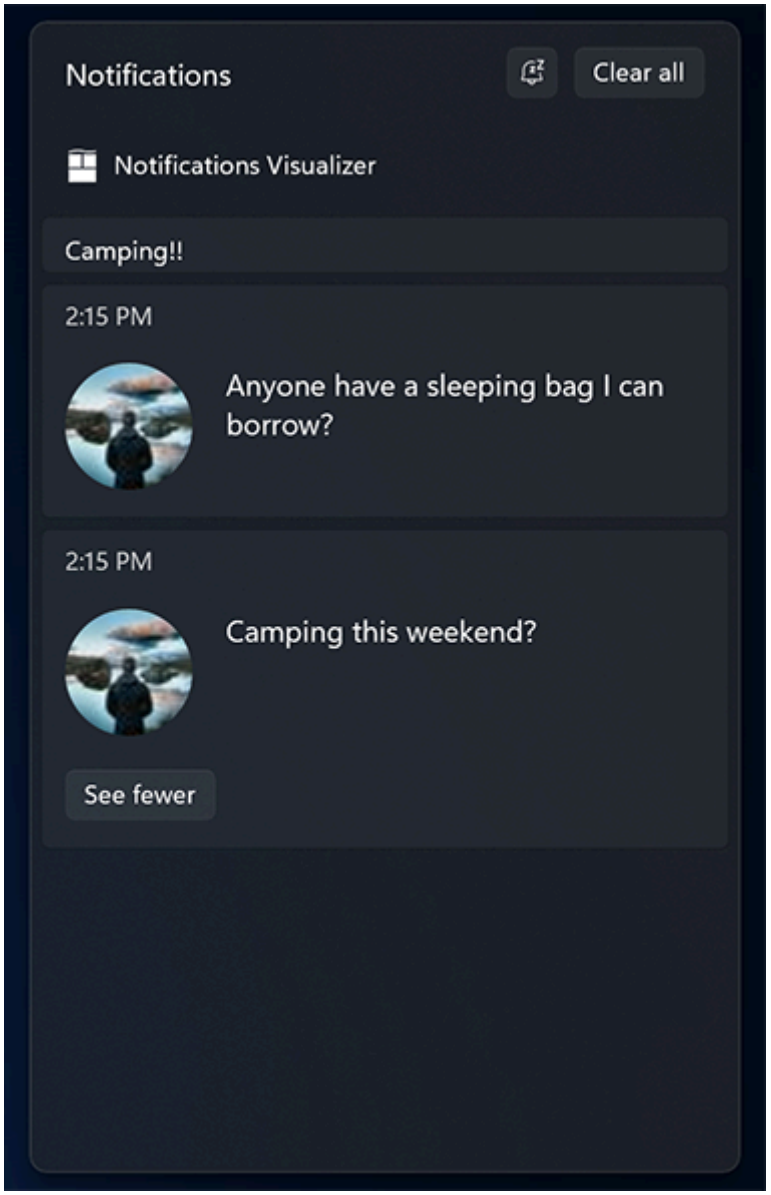
New in Creators Update: You can provide a progress bar on your app notification to keep the user informed of the progress of operations such as downloads.



To learn more about using a progress bar, please see Toast progress bar.

Headers

New in Creators Update: You can group notifications under headers within Notification Center. For example, you can group messages from a group chat under a header, or group notifications of a common theme under a header, or more.



To learn more about using headers, please see Toast headers.

Adaptive content

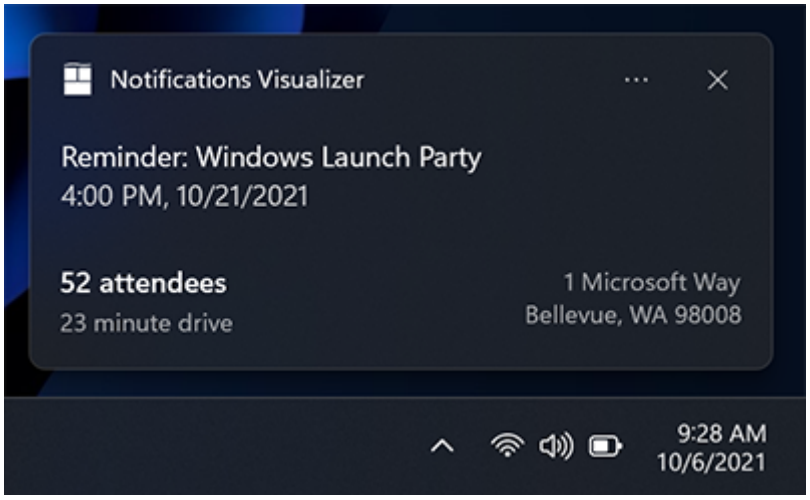
New in Anniversary Update: In addition to the content specified above, you can also display additional adaptive content that is visible when the toast is expanded.

This additional content is specified using Adaptive, which you can learn more about by reading the Adaptive Tiles documentation.

Note that any adaptive content must be contained within an **AdaptiveGroup**. Otherwise it will not be rendered using adaptive.

Columns and text elements

Here's an example where columns and some advanced adaptive text elements are used. Since the text elements are within an **AdaptiveGroup**, they support all the rich adaptive styling properties.



Windows App SDK

C#

```
// The Microsoft.Windows.AppNotifications.Builder syntax does not
currently support adaptive text elements.
```

Buttons

Buttons make your toast interactive, letting the user take quick actions on your app notification without interrupting their current workflow. For example, users can reply to a message directly from within a toast, or delete an email without even opening the email app. Buttons appear in the expanded portion of your notification.

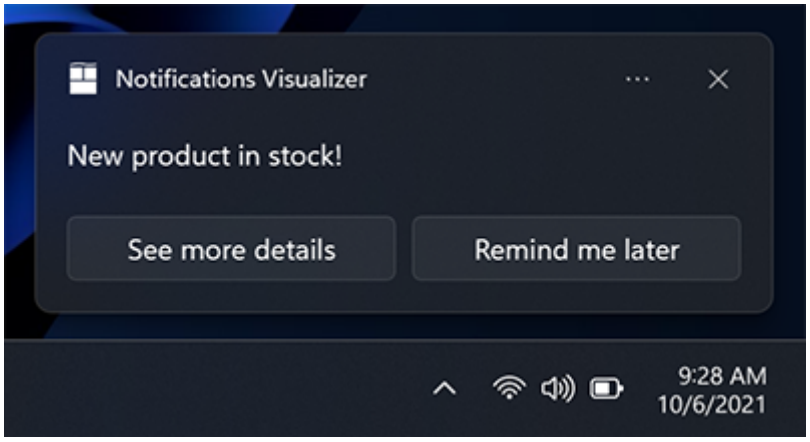
To learn more about implementing buttons end-to-end, see Send local toast.

Buttons can activate an app in the following ways:

- The app is activated in the foreground, with an argument that can be used to navigate to a specific page/context.
- Another app is activated via protocol launch.

- Background activation is supported explicitly for UWP apps. For Windows App SDK apps, the app is always launched in the foreground. The app can call AppInstance.GetActivatedEventArgs to detect if the activation was launched by a notification and determine from the passed arguments whether to fully launch the foreground app or just handle the notification and exit.
- System actions, such as snoozing or dismissing the notification, are supported both for UWP apps and for Windows App SDK. The **AppNotificationBuilder** APIs don't support this scenario but Windows App SDK apps can implement this scenario using the **Microsoft.Windows.AppNotifications.Builder** APIs or raw XML.

> **Note**
>
> You can only have up to 5 buttons (including context menu items which we discuss later).



Windows App SDK

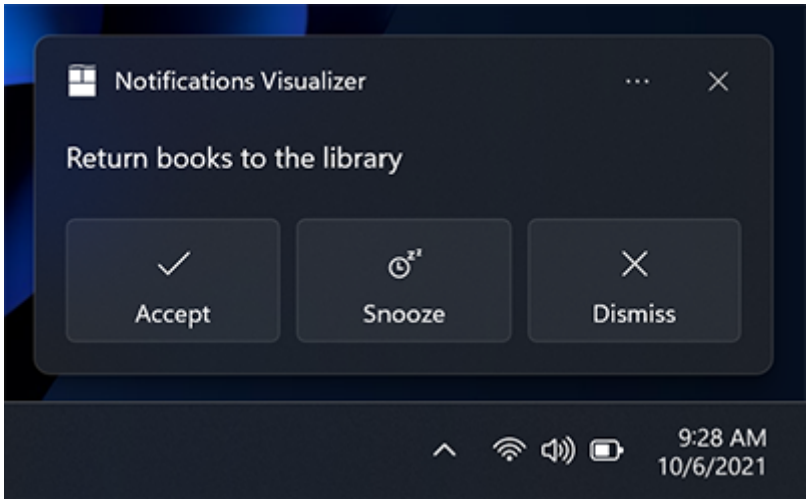
C#

```
new ToastContentBuilder()
    var builder = new AppNotificationBuilder()
        .AddText("New product in stock!")
        .AddButton(new AppNotificationButton("See more details")
            .AddArgument("action", "viewDetails"))
            .AddArgument("contentId", "351")
        .AddButton(new AppNotificationButton("Remind me later")
            .AddArgument("action", "remindLater"))
            .AddArgument("contentId", "351");
```

Buttons with icons

You can add icons to your buttons. These icons are white transparent 16x16 pixel images at 100% scaling, and should have no padding included in the image itself. If you choose to provide icons on a toast notification, you must provide icons for ALL of your buttons in the notification, as it transforms the style of your buttons into icon buttons.

> **Note**
>
> For accessibility, be sure to include a contrast-white version of the icon (a black icon for white backgrounds), so that when the user turns on High Contrast White mode, your icon is visible. For more information, see Tile and toast notification support for language, scale, and high contrast.



Windows App SDK

C#

```
new ToastContentBuilder()
    var builder = new AppNotificationBuilder()
        .AddText("Return books to the library.")
        .AddButton(new AppNotificationButton("Accept")
            .AddArgument("action", "accept")
            .SetIcon(new Uri("ms-appx:///Images/Accept.png")))
        .AddButton(new AppNotificationButton("Snooze")
            .AddArgument("action", "snooze")
            .SetIcon(new Uri("ms-appx:///Images/Snooze.png")))
        .AddButton(new AppNotificationButton("Dismiss")
            .AddArgument("action", "dismiss")
            .SetIcon(new Uri("ms-appx:///Images/Dismiss.png")));
```

New in Windows 11 Update: You can add tooltips to your icons with the **HintToolTip** property in XML. This is ideal if your buttons have icons but no content, as this will make

sure you can pass text that Windows Narrator can read. However, if content is present, then Narrator will read the content, no matter what is passed in the tooltip.

Windows App SDK

C#

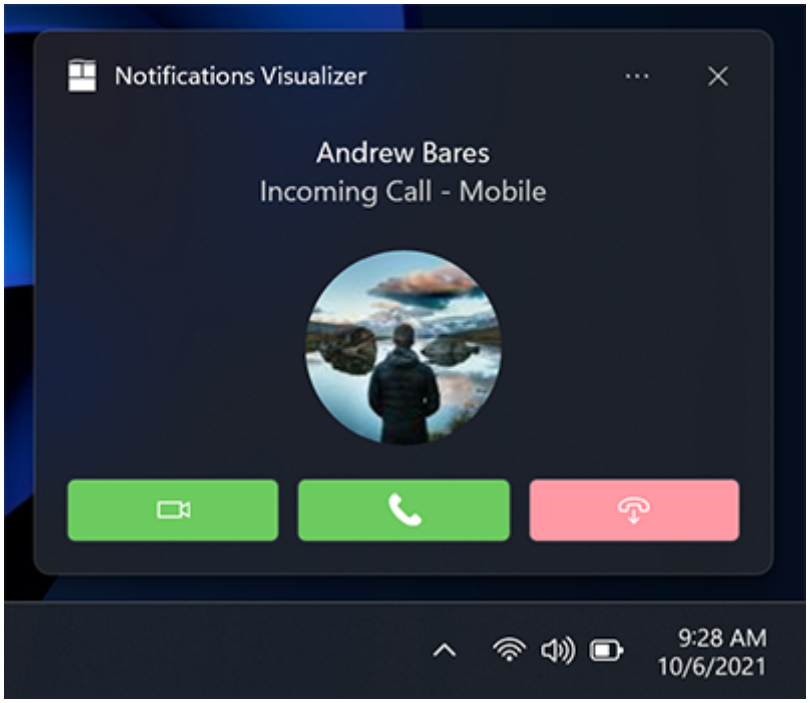
```
var button = new AppNotificationButton("Reply")
    .AddArgument("action", "reply");

if (AppNotificationButton.IsToolTipSupported())
{
    button.ToolTip = "Click to reply.";
}

var builder = new AppNotificationBuilder()
    .AddText("Notification text.")
    .AddButton(button);
```

Buttons with colors

New in Windows 11 Update: You can add red or green colors to your buttons by adding the **useButtonStyle** attribute to the **toast** XML element and the **hint-buttonStyle** attribute to the action XML element as seen below.



Windows App SDK

C#

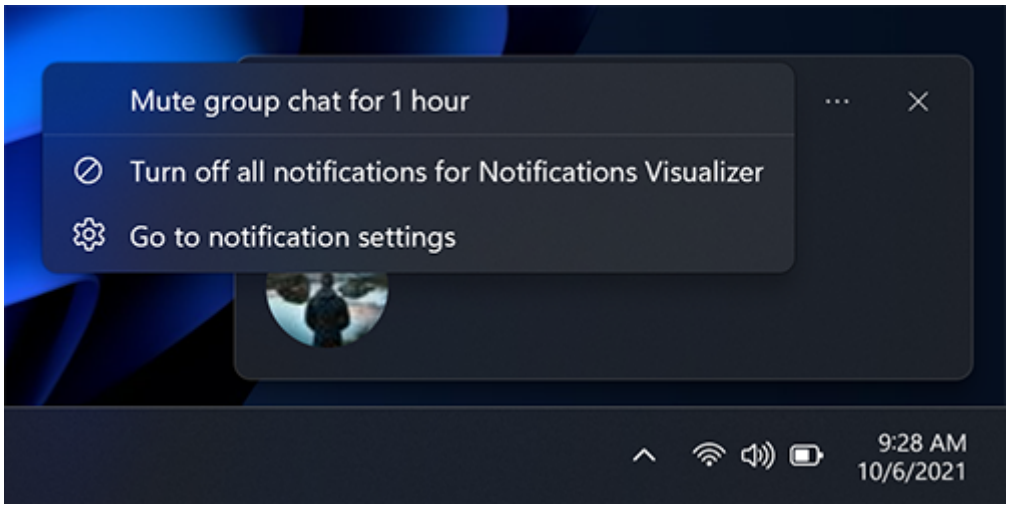
```
var builder = new AppNotificationBuilder()
    .SetScenario(AppNotificationScenario.IncomingCall)
    .AddText("Andrew Bares", new AppNotificationTextProperties()
        .SetIncomingCallAlignment())
      .AddText("Incoming Call - Mobile", new
AppNotificationTextProperties()
        .SetIncomingCallAlignment())
      .SetInlineImage(new Uri("ms-appx:///Images/Profile.png"),
        AppNotificationImageCrop.Circle)
    .AddButton(new AppNotificationButton()
        .SetToolTip("Answer Video Call")
        .SetButtonStyle(AppNotificationButtonStyle.Success)
        .SetIcon(new Uri("ms-appx:///Images/Video.png"))
        .AddArgument("videoId", "123"))
    .AddButton(new AppNotificationButton()
        .SetToolTip("Answer Phone Call")
        .SetButtonStyle(AppNotificationButtonStyle.Success)
        .SetIcon(new Uri("ms-appx:///Images/Call.png"))
        .AddArgument("callId", "123"))
    .AddButton(new AppNotificationButton()
        .SetToolTip("Hang Up")
        .SetButtonStyle(AppNotificationButtonStyle.Critical)
        .SetIcon(new Uri("ms-appx:///Images/HangUp.png"))
        .AddArgument("hangUpId", "123"));
```

Context menu actions

New in Anniversary Update: You can add additional context menu actions to the existing context menu that appears when the user right clicks your toast notification or selects the context menu icon.

> ⓘ **Note**
>
> On older devices, these additional context menu actions will simply appear as normal buttons on your notification.

The additional context menu actions you add (such as "Mute group chat for 1 hour") appear above the two default system entries.



Windows App SDK

C#

```
var builder = new AppNotificationBuilder()
    .AddText("Camping this weekend?")
    .SetAppLogoOverride(new Uri("ms-appx:///images/Reply.png"),
AppNotificationImageCrop.Circle)
    .AddButton(new AppNotificationButton("Mute group chat for 1 hour")
        .AddArgument("action", "mute")
        .SetContextMenuPlacement());
```

> **Note**
>
> Additional context menu items contribute to the total limit of 5 buttons on a toast.

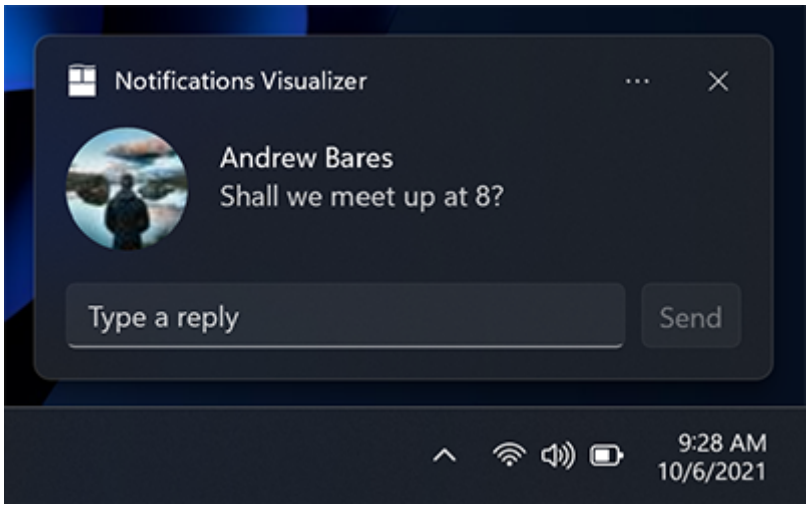
Activation of additional context menu items is handled identical to toast buttons.

Inputs

Inputs are specified within the **Actions** region of the app notification, meaning they are only visible when the notification is expanded.

Quick reply text box

To enable a quick reply text box (for example, in a messaging app) add a text input and a button, and reference the ID of the text input field so that the button is displayed next to the input field. The optional icon for the button, if provided, should be a 32x32 pixel image with no padding, white pixels set to transparent, and 100% scale.



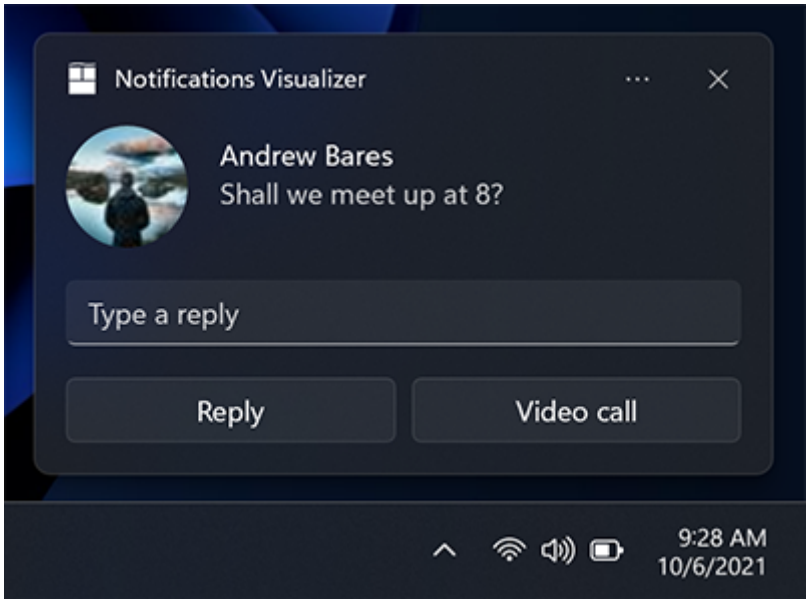
Windows App SDK

C#

```
var builder = new AppNotificationBuilder()
    .AddTextBox("textBox", "Type a reply", "Reply")
    .AddButton(AppNotificationButton("Send")
        .AddArguments("action", "Send")
        .SetInputId("textBox"))
    .BuildNotification();
```

Inputs with buttons bar

You also can have one (or many) inputs with normal buttons displayed below the inputs.



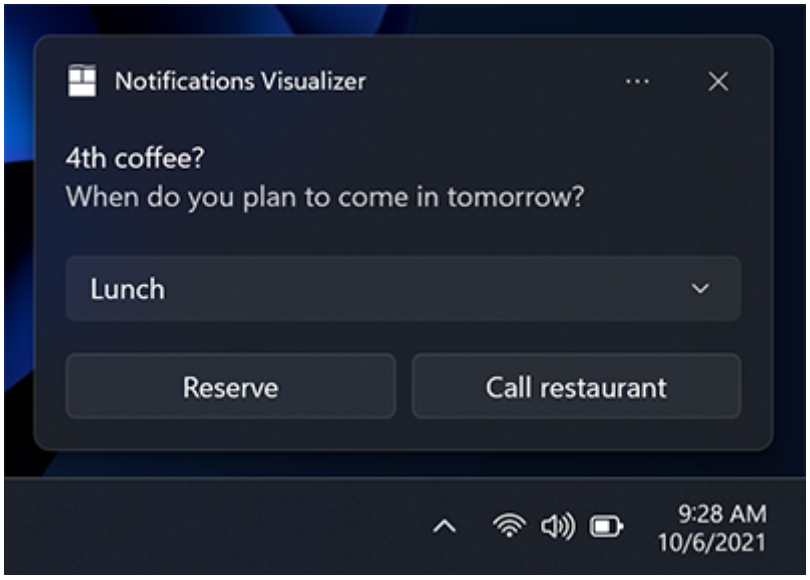
Windows App SDK

C#

```
// The Microsoft.Windows.AppNotifications.Builder syntax does not
currently support quick reply text boxes.
```

Selection input

In addition to text boxes, you can also use a selection menu.



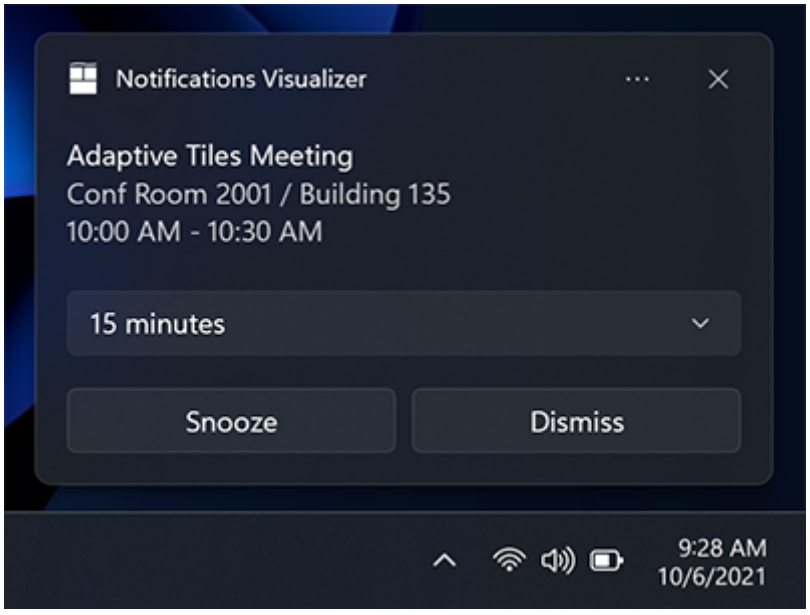
Windows App SDK

C#

```
var builder = new AppNotificationBuilder()
    .AddText("4th coffee?")
    .AddText("When do you plan to come in tomorrow?")
    .AddComboBox(new AppNotificationComboBox("time")
        .SetTitle("Select an item:")
        .AddItem("breakfast", "Breakfast")
        .AddItem("lunch", "Lunch")
        .AddItem("dinner", "Dinner")
        .SetSelectedItem("lunch"))
    .AddButton(new AppNotificationButton("Reply")
        .AddArgument("action", "reply")
        .AddArgument("threadId", "9218")
        .SetContextMenuPlacement())
    .AddButton(new AppNotificationButton("Call restaurant")
        .AddArgument("action", "videocall")
        .AddArgument("threadId", "9218")
        .SetContextMenuPlacement());
```

Snooze/dismiss

Using a selection menu and two buttons, we can create a reminder notification that utilizes the system snooze and dismiss actions. Make sure to set the scenario to "Reminder" for the notification to behave like a reminder.



We link the Snooze button to the selection menu input using the **SelectionBoxId** property on the toast button.

The **Microsoft.Windows.AppNotifications.Builder** syntax does not currently support system activation. But this scenario is supported for Windows App SDK apps, and you can build notifications for this scenario using the `Microsoft.Toolkit.Uwp.Notifications` APIs or raw XML.

Windows App SDK

C#

```
// The Microsoft.Windows.AppNotifications.Builder syntax does not
currently support system activation.
// But this scenario is supported for Windows App SDK apps, and you can
build notifications for this
// scenario using the `Microsoft.Toolkit.Uwp.Notifications` APIs or raw
XML.
```

To use the system snooze and dismiss actions:

- Specify a **ToastButtonSnooze** or **ToastButtonDismiss**
- Optionally specify a custom content string:

- If you don't provide a string, we'll automatically use localized strings for "Snooze" and "Dismiss".
- Optionally specify the **SelectionBoxId**:
- If you don't want the user to select a snooze interval and instead just want your notification to snooze only once for a system-defined time interval (that is consistent across the OS), then don't construct any <input> at all.
- If you want to provide snooze interval selections: - Specify **SelectionBoxId** in the snooze action - Match the id of the input with the **SelectionBoxId** of the snooze action - Specify **ToastSelectionBoxItem**'s value to be a nonNegativeInteger which represents snooze interval in minutes.

Audio

Custom audio has always been supported on Mobile, and is supported in Desktop Version 1511 (build 10586) or later. Custom audio can be referenced via the following paths:

- ms-appx:///
- ms-appdata:///

Windows App SDK

C#

```
var builder = new AppNotificationBuilder()
    .AddText("Notification text.")
    .SetAudioUri(new Uri("ms-appx:///Audio/NotificationSound.mp3"));
```

Alternatively, you can pick from the list of ms-winsoundevents, which have always been supported on both platforms.

Windows App SDK

C#

```
var builder = new AppNotificationBuilder()
    .AddText("Notification text.")
    .SetAudioEvent(AppNotificationSoundEvent.Alarm,
AppNotificationAudioLooping.Loop);
```

See the audio schema page for information on audio in app notifications. To learn how to send an app notification that uses custom audio, see custom audio on toasts.

Scenarios

To create important notifications, alarms, reminders, and incoming call notifications, you simply use a normal app notification with a **Scenario** value assigned to it. The scenario adjusts a few behaviors to create a consistent and unified user experience. There are four possible **Scenario** values:

- **Reminder**
- **Alarm**
- **IncomingCall**
- **Urgent**

Reminders

In the reminder scenario, the notification will stay on screen until the user dismisses it or takes action. On Windows Mobile, the app notification will also show pre-expanded. A reminder sound will be played. You must provide at least one button on your app notification. Otherwise, the notification will be treated as a normal notification.

Windows App SDK

C#

```
var builder = new AppNotificationBuilder()
    .AddText("Notification text.")
    .SetScenario(AppNotificationScenario.Reminder);
```

Alarms

Alarms behave the same as reminders, except alarms will additionally loop audio with a default alarm sound. You must provide at least one button on your app notification. Otherwise, the notification will be treated as a normal notification.

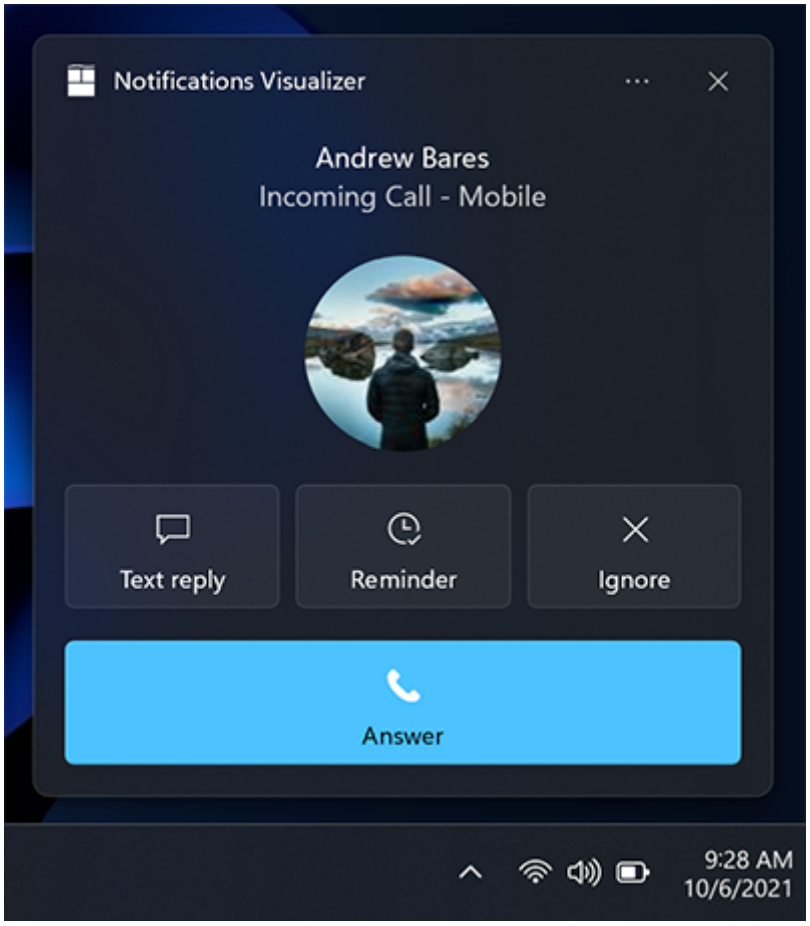
Windows App SDK

C#

```
var builder = new AppNotificationBuilder()
    .AddText("Notification text.")
    .SetScenario(AppNotificationScenario.Alarm)
    .AddButton(new AppNotificationButton("Dismiss")
        .AddArgument("action", "dismiss"));
```

Incoming calls

Incoming call notifications are displayed pre-expanded in a special call format and stay on the user's screen till dismissed. Ringtone audio will loop by default. On Windows Mobile devices, they display full screen.



Windows App SDK

C#

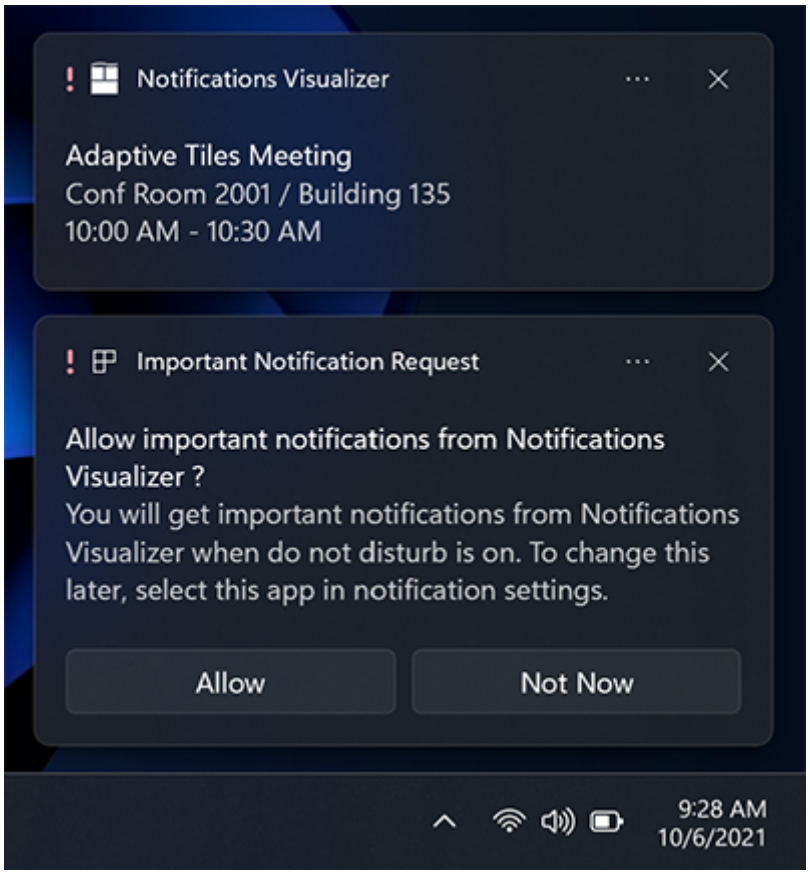
```
var builder = new AppNotificationBuilder()
    .SetScenario(AppNotificationScenario.IncomingCall)
    .AddText("Andrew Bares", new AppNotificationTextProperties()
        .SetIncomingCallAlignment())
    .AddText("incoming call - mobile", new
AppNotificationTextProperties()
        .SetIncomingCallAlignment())
```

```
        .SetInlineImage(new Uri("ms-appx:///images/profile.png"),
          AppNotificationImageCrop.Circle)
    .AddButton(new AppNotificationButton("Text reply")
        .SetToolTip("Text reply")
        .SetIcon(new Uri("ms-appx:///images/reply.png"))
        .AddArgument("textId", "123"))
    .AddButton(new AppNotificationButton("Reminder")
        .SetToolTip("Reminder")
        .SetIcon(new Uri("ms-appx:///images/reminder.png"))
        .AddArgument("reminderId", "123"))
    .AddButton(new AppNotificationButton("Ignore")
        .SetToolTip("Ignore")
        .SetIcon(new Uri("ms-appx:///images/ignore.png"))
        .AddArgument("ignoreId", "123"))
    .AddButton(new AppNotificationButton("Answer")
        .SetToolTip("Answer")
        .SetIcon(new Uri("ms-appx:///images/answer.png"))
        .AddArgument("answerId", "123"));
```

Important Notifications

> ⓘ **Important**
>
> **Requires**: You must be running Windows Insider Preview Build 22546 or later to use important notifications.

Important notifications allow users to have more control over what 1st party and 3rd party apps can send them high-priority app notifications (urgent/important) that can break through Focus Assist (Do not Disturb). This can be modified in the notifications settings.



Windows App SDK

C#

```
var builder = new AppNotificationBuilder()
    .AddText("Adaptive Tiles Meeting",
        new AppNotificationTextProperties()
            .SetMaxLines(1))
    .AddText("Conf Room 2001 / Building 135")
    .AddText("10:00 AM - 10:30 AM");

if (AppNotificationBuilder.IsUrgentScenarioSupported())
{
    builder.SetScenario(AppNotificationScenario.Urgent);
}
```

Localization and accessibility

Your tiles and app notifications can load strings and images tailored for display language, display scale factor, high contrast, and other runtime contexts. For more info, see Tile and toast notification support for language, scale, and high contrast.

Handling activation

To learn how to handle app activations (the user clicking your toast or buttons on the toast), see Send local toast.

Toast content schema

Article • 05/24/2022

The following describes all of the properties and elements within toast content.

If you would rather use raw XML instead of the Notifications library, please see the XML schema.

ToastContent

- ToastVisual
  - ToastBindingGeneric
    - IToastBindingGenericChild
    - ToastGenericAppLogo
    - ToastGenericHeroImage
    - ToastGenericAttributionText
- IToastActions
- ToastAudio
- ToastHeader

ToastContent

ToastContent is the top level object that describes a notification's content, including visuals, actions, and audio.

Property	Type	Required	Description
Launch	string	false	A string that is passed to the application when it is activated by the Toast. The format and contents of this string are defined by the app for its own use. When the user taps or clicks the Toast to launch its associated app, the launch string provides the context to the app that allows it to show the user a view relevant to the Toast content, rather than launching in its default way.
Visual	ToastVisual	true	Describes the visual portion of the toast notification.
Actions	IToastActions	false	Optionally create custom actions with buttons and inputs.
Audio	ToastAudio	false	Describes the audio portion of the toast notification.
ActivationType	ToastActivationType	false	Specifies what activation type will be used when the user clicks the body of this Toast.

Property	Type	Required	Description
ActivationOptions	ToastActivationOptions	false	New in Creators Update: Additional options relating to activation of the toast notification.
Scenario	ToastScenario	false	Declares the scenario your toast is used for, like an alarm or reminder.
DisplayTimestamp	DateTimeOffset?	false	New in Creators Update: Override the default timestamp with a custom timestamp representing when your notification content was actually delivered, rather than the time the notification was received by the Windows platform.
Header	ToastHeader	false	New in Creators Update: Add a custom header to your notification to group multiple notifications together within Action Center.

ToastScenario

Specifies what scenario the toast represents.

Value	Meaning
Default	The normal toast behavior.
Reminder	A reminder notification. This will be displayed pre-expanded and stay on the user's screen till dismissed.
Alarm	An alarm notification. This will be displayed pre-expanded and stay on the user's screen till dismissed. Audio will loop by default and will use alarm audio.
IncomingCall	An incoming call notification. This will be displayed pre-expanded in a special call format and stay on the user's screen till dismissed. Audio will loop by default and will use ringtone audio.

ToastVisual

The visual portion of toasts contains the bindings, which contains text, images, adaptive content, and more.

Property	Type	Required	Description
BindingGeneric	ToastBindingGeneric	true	The generic toast binding, which can be rendered on all devices. This binding is required and cannot be null.
BaseUri	Uri	false	A default base URL that is combined with relative URLs in image source attributes.

Property	Type	Required	Description
AddImageQuery	bool?	false	Set to "true" to allow Windows to append a query string to the image URL supplied in the toast notification. Use this attribute if your server hosts images and can handle query strings, either by retrieving an image variant based on the query strings or by ignoring the query string and returning the image as specified without the query string. This query string specifies scale, contrast setting, and language; for instance, a value of "www.website.com/images/hello.png" given in the notification becomes "www.website.com/images/hello.png?ms-scale=100&ms-contrast=standard&ms-lang=en-us"
Language	string	false	The target locale of the visual payload when using localized resources, specified as BCP-47 language tags such as "en-US" or "fr-FR". This locale is overridden by any locale specified in binding or text. If not provided, the system locale will be used instead.

ToastBindingGeneric

The generic binding is the default binding for toasts, and is where you specify the text, images, adaptive content, and more.

Property	Type	Required	Description
Children	IList<IToastBindingGenericChild>	false	The contents of the body of the Toast, which can include text, images, and groups (added in Anniversary Update). Text elements must come before any other elements, and only 3 text elements are supported. If a text element is placed after any other element, it will either be pulled to the top or dropped. And finally, certain text properties like HintStyle aren't supported on the root children text elements, and only work inside an AdaptiveSubgroup. If you use AdaptiveGroup on devices without the Anniversary Update, the group content will simply be dropped.
AppLogoOverride	ToastGenericAppLogo	false	An optional logo to override the app logo.

Property	Type	Required	Description
HeroImage	ToastGenericHeroImage	false	An optional featured "hero" image that is displayed on the toast and within Action Center.
Attribution	ToastGenericAttributionText	false	Optional attribution text which will be displayed at the bottom of the toast notification.
BaseUri	Uri	false	A default base URL that is combined with relative URLs in image source attributes.
AddImageQuery	bool?	false	Set to "true" to allow Windows to append a query string to the image URL supplied in the toast notification. Use this attribute if your server hosts images and can handle query strings, either by retrieving an image variant based on the query strings or by ignoring the query string and returning the image as specified without the query string. This query string specifies scale, contrast setting, and language; for instance, a value of "www.website.com/images/hello.png" given in the notification becomes "www.website.com/images/hello.png?ms-scale=100&ms-contrast=standard&ms-lang=en-us"
Language	string	false	The target locale of the visual payload when using localized resources, specified as BCP-47 language tags such as "en-US" or "fr-FR". This locale is overridden by any locale specified in binding or text. If not provided, the system locale will be used instead.

IToastBindingGenericChild

Marker interface for toast child elements that include text, images, groups, and more.

Implementations
AdaptiveText
AdaptiveImage
AdaptiveGroup
AdaptiveProgressBar

AdaptiveText

An adaptive text element. If placed in the top level ToastBindingGeneric.Children, only HintMaxLines will be applied. But if this is placed as a child of a group/subgroup, full text styling is supported.

Property	Type	Required	Description
Text	string or BindableString	false	The text to display. Data binding support added in Creators Update, but only works for top-level text elements.
HintStyle	AdaptiveTextStyle	false	The style controls the text's font size, weight, and opacity. Only works for text elements inside a group/subgroup.
HintWrap	bool?	false	Set this to true to enable text wrapping. Top-level text elements ignore this property and always wrap (you can use HintMaxLines = 1 to disable wrapping for top-level text elements). Text elements inside groups/subgroups default to false for wrapping.
HintMaxLines	int?	false	The maximum number of lines the text element is allowed to display.
HintMinLines	int?	false	The minimum number of lines the text element must display. Only works for text elements inside a group/subgroup.
HintAlign	AdaptiveTextAlign	false	The horizontal alignment of the text. Only works for text elements inside a group/subgroup.
Language	string	false	The target locale of the XML payload, specified as a BCP-47 language tags such as "en-US" or "fr-FR". The locale specified here overrides any other specified locale, such as that in binding or visual. If this value is a literal string, this attribute defaults to the user's UI language. If this value is a string reference, this attribute defaults to the locale chosen by Windows Runtime in resolving the string.

BindableString

A binding value for strings.

Property	Type	Required	Description
BindingName	string	true	Gets or sets the name that maps to your binding data value.

AdaptiveTextStyle

Text style controls font size, weight, and opacity. Subtle opacity is 60% opaque.

Value	Meaning
Default	Default value. Style is determined by the renderer.
Caption	Smaller than paragraph font size.
CaptionSubtle	Same as Caption but with subtle opacity.
Body	Paragraph font size.
BodySubtle	Same as Body but with subtle opacity.
Base	Paragraph font size, bold weight. Essentially the bold version of Body.
BaseSubtle	Same as Base but with subtle opacity.
Subtitle	H4 font size.
SubtitleSubtle	Same as Subtitle but with subtle opacity.
Title	H3 font size.
TitleSubtle	Same as Title but with subtle opacity.
TitleNumeral	Same as Title but with top/bottom padding removed.
Subheader	H2 font size.
SubheaderSubtle	Same as Subheader but with subtle opacity.
SubheaderNumeral	Same as Subheader but with top/bottom padding removed.
Header	H1 font size.
HeaderSubtle	Same as Header but with subtle opacity.
HeaderNumeral	Same as Header but with top/bottom padding removed.

AdaptiveTextAlign

Controls the horizontal alignmen of text.

Value	Meaning
Default	Default value. Alignment is automatically determined by the renderer.
Auto	Alignment determined by the current language and culture.
Left	Horizontally align the text to the left.
Center	Horizontally align the text in the center.
Right	Horizontally align the text to the right.

AdaptiveImage

An inline image.

Property	Type	Required	Description
Source	string	true	The URL to the image. ms-appx, ms-appdata, and http are supported. As of the Fall Creators Update, web images can be up to 3 MB on normal connections and 1 MB on metered connections. On devices not yet running the Fall Creators Update, web images must be no larger than 200 KB.
HintCrop	AdaptiveImageCrop	false	New in Anniversary Update: Control the desired cropping of the image.
HintRemoveMargin	bool?	false	By default, images inside groups/subgroups have an 8px margin around them. You can remove this margin by setting this property to true.
HintAlign	AdaptiveImageAlign	false	The horizontal alignment of the image. Only works for images inside a group/subgroup.
AlternateText	string	false	Alternate text describing the image, used for accessibility purposes.
AddImageQuery	bool?	false	Set to "true" to allow Windows to append a query string to the image URL supplied in the toast notification. Use this attribute if your server hosts images and can handle query strings, either by retrieving an image variant based on the query strings or by ignoring the query string and returning the image as specified without the query string. This query string specifies scale, contrast setting, and language; for instance, a value of "www.website.com/images/hello.png" given in the notification becomes "www.website.com/images/hello.png?ms-scale=100&ms-contrast=standard&ms-lang=en-us"

AdaptiveImageCrop

Specifies the desired cropping of the image.

Value	Meaning
Default	Default value. Cropping behavior determined by renderer.
None	Image is not cropped.

Value	Meaning
Circle	Image is cropped to a circle shape.

AdaptiveImageAlign

Specifies the horizontal alignment for an image.

Value	Meaning
Default	Default value. Alignment behavior determined by renderer.
Stretch	Image stretches to fill available width (and potentially available height too, depending on where the image is placed).
Left	Align the image to the left, displaying the image at its native resolution.
Center	Align the image in the center horizontally, displayign the image at its native resolution.
Right	Align the image to the right, displaying the image at its native resolution.

AdaptiveGroup

New in Anniversary Update: Groups semantically identify that the content in the group must either be displayed as a whole, or not displayed if it cannot fit. Groups also allow creating multiple columns.

Property	Type	Required	Description
Children	IList<AdaptiveSubgroup>	false	Subgroups are displayed as vertical columns. You must use subgroups to provide any content inside an AdaptiveGroup.

AdaptiveSubgroup

New in Anniversary Update: Subgroups are vertical columns that can contain text and images.

Property	Type	Required	Description
Children	IList<IAdaptiveSubgroupChild>	false	AdaptiveText and AdaptiveImage are valid children of subgroups.
HintWeight	int?	false	Control the width of this subgroup column by specifying the weight, relative to the other subgroups.
HintTextStacking	AdaptiveSubgroupTextStacking	false	Control the vertical alignment of this subgroup's content.

IAdaptiveSubgroupChild

Marker interface for subgroup children.

Implementations
AdaptiveText
AdaptiveImage

AdaptiveSubgroupTextStacking

TextStacking specifies the vertical alignment of content.

Value	Meaning
Default	Default value. Renderer automatically selects the default vertical alignment.
Top	Vertical align to the top.
Center	Vertical align to the center.
Bottom	Vertical align to the bottom.

AdaptiveProgressBar

New in Creators Update: A progress bar. Only supported on toasts on Desktop, build 15063 or later.

Property	Type	Required	Description
Title	string or BindableString	false	Gets or sets an optional title string. Supports data binding.
Value	double or AdaptiveProgressBarValue or BindableProgressBarValue	false	Gets or sets the value of the progress bar. Supports data binding. Defaults to 0.
ValueStringOverride	string or BindableString	false	Gets or sets an optional string to be displayed instead of the default percentage string. If this isn't provided, something like "70%" will be displayed.
Status	string or BindableString	true	Gets or sets a status string (required), which is displayed underneath the progress bar on the left. This string should reflect the status of the operation, like "Downloading..." or "Installing..."

AdaptiveProgressBarValue

A class that represents the progress bar's value.

Property	Type	Required	Description
Value	double	false	Gets or sets the value (0.0 - 1.0) representing the percent complete.
IsIndeterminate	bool	false	Gets or sets a value indicating whether the progress bar is indeterminate. If this is true, **Value** will be ignored.

BindableProgressBarValue

A bindable progress bar value.

Property	Type	Required	Description
BindingName	string	true	Gets or sets the name that maps to your binding data value.

ToastGenericAppLogo

A logo to be displayed instead of the app logo.

Property	Type	Required	Description
Source	string	true	The URL to the image. ms-appx, ms-appdata, and http are supported. Http images must be 200 KB or less in size.
HintCrop	ToastGenericAppLogoCrop	false	Specify how you would like the image to be cropped.
AlternateText	string	false	Alternate text describing the image, used for accessibility purposes.

Property	Type	Required	Description
AddImageQuery	bool?	false	Set to "true" to allow Windows to append a query string to the image URL supplied in the toast notification. Use this attribute if your server hosts images and can handle query strings, either by retrieving an image variant based on the query strings or by ignoring the query string and returning the image as specified without the query string. This query string specifies scale, contrast setting, and language; for instance, a value of "www.website.com/images/hello.png" given in the notification becomes "www.website.com/images/hello.png?ms-scale=100&ms-contrast=standard&ms-lang=en-us"

ToastGenericAppLogoCrop

Controls the cropping of the app logo image.

Value	Meaning
Default	Cropping uses the default behavior of the renderer.
None	Image is not cropped, displayed square.
Circle	Image is cropped to a circle.

ToastGenericHeroImage

A featured "hero" image that is displayed on the toast and within Action Center.

Property	Type	Required	Description
Source	string	true	The URL to the image. ms-appx, ms-appdata, and http are supported. Http images must be 200 KB or less in size.
AlternateText	string	false	Alternate text describing the image, used for accessibility purposes.
AddImageQuery	bool?	false	Set to "true" to allow Windows to append a query string to the image URL supplied in the toast notification. Use this attribute if your server hosts images and can handle query strings, either by retrieving an image variant based on the query strings or by ignoring the query string and returning the image as specified without the query string. This query string specifies scale, contrast setting, and language; for instance, a value of "www.website.com/images/hello.png" given in the notification becomes "www.website.com/images/hello.png?ms-scale=100&ms-contrast=standard&ms-lang=en-us"

ToastGenericAttributionText

Attribution text displayed at the bottom of the toast notification.

Property	Type	Required	Description
Text	string	true	The text to display.
Language	string	false	The target locale of the visual payload when using localized resources, specified as BCP-47 language tags such as "en-US" or "fr-FR". If not provided, the system locale will be used instead.

IToastActions

Marker interface for toast actions/inputs.

Implementations
ToastActionsCustom
ToastActionsSnoozeAndDismiss

ToastActionsCustom

Implements IToastActions

Create your own custom actions and inputs, using controls like buttons, text boxes, and selection inputs.

Property	Type	Required	Description
Inputs	IList<IToastInput>	false	Inputs like text boxes and selection inputs. Only up to 5 inputs are allowed.
Buttons	IList<IToastButton>	false	Buttons are displayed after all the inputs (or adjacent to an input if the button is used as a quick reply button). Only up to 5 buttons are allowed (or fewer if you also have context menu items).
ContextMenuItems	IList<ToastContextMenuItem>	false	New in Anniversary Update: Custom context menu items, providing additional actions if the user right clicks the notification. You can only have up to 5 buttons and context menu items *combined*.

IToastInput

Marker interface for toast inputs.

Implementations
ToastTextBox
ToastSelectionBox

ToastTextBox

Implements IToastInput

A text box control that the user can type text into.

Property	Type	Required	Description
Id	string	true	The Id is required, and is used to map the user-inputted text into a key-value pair of id/value which your app later consumes.
Title	string	false	Title text to display above the text box.
PlaceholderContent	string	false	Placeholder text to be displayed on the text box when the user hasn't typed any text yet.
DefaultInput	string	false	The initial text to place in the text box. Leave this null for a blank text box.

ToastSelectionBox

Implements IToastInput

A selection box control, which lets users pick from a dropdown list of options.

Property	Type	Required	Description
Id	string	true	The Id is required. If the user selected this item, this Id will be passed back to your app's code, representing which selection they chose.
Content	string	true	Content is required, and is a string that is displayed on the selection item.

ToastSelectionBoxItem

A selection box item (an item that the user can select from the drop down list).

Property	Type	Required	Description

Property	Type	Required	Description
Id	string	true	The Id is required, and is used to map the user-inputted text into a key-value pair of id/value which your app later consumes.
Title	string	false	Title text to display above the selection box.
DefaultSelectionBoxItemId	string	false	This controls which item is selected by default, and refers to the Id property of the ToastSelectionBoxItem. If you do not provide this, the default selection will be empty (user sees nothing).
Items	IList<ToastSelectionBoxItem>	false	The selection items that the user can pick from in this SelectionBox. Only 5 items can be added.

IToastButton

Marker interface for toast buttons.

Implementations
ToastButton
ToastButtonSnooze
ToastButtonDismiss

ToastButton

Implements IToastButton

A button that the user can click.

Property	Type	Required	Description
Content	string	true	Required. The text to display on the button.
Arguments	string	true	Required. App-defined string of arguments that the app will later receive if the user clicks this button.
ActivationType	ToastActivationType	false	Controls what type of activation this button will use when clicked. Defaults to Foreground.

Property	Type	Required	Description
ActivationOptions	ToastActivationOptions	false	New in Creators Update: Gets or sets additional options relating to activation of the toast button.

ToastActivationType

Decides the type of activation that will be used when the user interacts with a specific action.

Value	Meaning
Foreground	Default value. Your foreground app is launched.
Background	Your corresponding background task (assuming you set everything up) is triggered, and you can execute code in the background (like sending the user's quick reply message) without interrupting the user.
Protocol	Launch a different app using protocol activation.

ToastActivationOptions

New in Creators Update: Additional options relating to activation.

Property	Type	Required	Description
AfterActivationBehavior	ToastAfterActivationBehavior	false	New in Fall Creators Update: Gets or sets the behavior that the toast should use when the user invokes this action. This only works on Desktop, for ToastButton and ToastContextMenuItem.
ProtocolActivationTargetApplicationPfn	string	false	If you are using *ToastActivationType.Protocol*, you can optionally specify the target PFN, so that regardless of whether multiple apps are registered to handle the same protocol uri, your desired app will always be launched.

ToastAfterActivationBehavior

Specifies the behavior that the toast should use when the user takes action on the toast.

Value	Meaning

Value	Meaning
Default	Default behavior. The toast will be dismissed when the user takes action on the toast.
PendingUpdate	After the user clicks a button on your toast, the notification will remain present, in a "pending update" visual state. You should immediately update your toast from a background task so that the user does not see this "pending update" visual state for too long.

ToastButtonSnooze

Implements IToastButton

A system-handled snooze button that automatically handles snoozing of the notification.

Property	Type	Required	Description
CustomContent	string	false	Optional custom text displayed on the button that overrides the default localized "Snooze" text.

ToastButtonDismiss

Implements IToastButton

A system-handled dismiss button that dismisses the notification when clicked.

Property	Type	Required	Description
CustomContent	string	false	Optional custom text displayed on the button that overrides the default localized "Dismiss" text.

ToastActionsSnoozeAndDismiss

*Implements IToastActions

Automatically constructs a selection box for snooze intervals, and snooze/dismiss buttons, all automatically localized, and snoozing logic is automatically handled by the system.

Property	Type	Required	Description
ContextMenuItems	IList<ToastContextMenuItem>	false	New in Anniversary Update: Custom context menu items, providing additional actions if the user right clicks the notification. You can only have up to 5 items.

ToastContextMenuItem

A context menu item entry.

Property	Type	Required	Description
Content	string	true	Required. The text to display.
Arguments	string	true	Required. App-defined string of arguments that the app can later retrieve once it is activated when the user clicks the menu item.
ActivationType	ToastActivationType	false	Controls what type of activation this menu item will use when clicked. Defaults to Foreground.
ActivationOptions	ToastActivationOptions	false	New in Creators Update: Additional options relating to activation of the toast context menu item.

ToastAudio

Specify audio to be played when the Toast notification is received.

Property	Type	Required	Description
Src	uri	false	The media file to play in place of the default sound. Only ms-appx and ms-resource are supported. All else (ms-appdata, http, C:, etc.) is not supported.
Loop	boolean	false	Set to true if the sound should repeat as long as the Toast is shown; false to play only once (default).
Silent	boolean	false	True to mute the sound; false to allow the toast notification sound to play (default).

ToastHeader

New in Creators Update: A custom header that groups multiple notifications together within Action Center.

Property	Type	Required	Description
Id	string	true	A developer-created identifier that uniquely identifies this header. If two notifications have the same header id, they will be displayed underneath the same header in Action Center.
Title	string	true	A title for the header.

Property	Type	Required	Description
Arguments	string	true	Gets or sets a developer-defined string of arguments that is returned to the app when the user clicks this header. Cannot be null.
ActivationType	ToastActivationType	false	Gets or sets the type of activation this header will use when clicked. Defaults to Foreground. Note that only Foreground and Protocol are supported.
ActivationOptions	ToastActivationOptions	false	Gets or sets additional options relating to activation of the toast header.

Schedule a toast notification

Article • 10/06/2022

Scheduled toast notifications allow you to schedule a notification to appear at a later time, regardless of whether your app is running at that time. This is useful for scenarios like displaying reminders or other follow-up tasks for the user, where the time and content of the notification is known ahead-of-time.

Note that scheduled toast notifications have a delivery window of 5 minutes. If the computer is turned off during the scheduled delivery time, and remains off for longer than 5 minutes, the notification will be "dropped" as no longer relevant to the user. If you need guaranteed delivery of notifications regardless of how long the computer was off, we recommend using a background task with a time trigger, as illustrated in this code sample.

> **Important**
>
> Desktop applications (both packaged and unpackaged) have slightly different steps for sending notifications and handling activation. Follow along with the instructions below, however replace `ToastNotificationManager` with the `DesktopNotificationManagerCompat` class from the **desktop apps** documentation.

> **Important APIs**: ScheduledToastNotification Class

Prerequisites

To fully understand this topic, the following will be helpful...

- A working knowledge of toast notification terms and concepts. For more information, see Toast and action center overview.
- A familiarity with Windows 10 toast notification content. For more information, see toast content documentation.
- A Windows 10 UWP app project

Step 1: Install NuGet package

Install the Microsoft.Toolkit.Uwp.Notifications NuGet package. Our code sample will use this package. At the end of the article we'll provide the "plain" code snippets that

don't use any NuGet packages. This package allows you to create toast notifications without using XML.

Step 2: Add namespace declarations

```
C#

using Microsoft.Toolkit.Uwp.Notifications; // Notifications library
```

Step 3: Schedule the notification

We'll use a simple text-based notification reminding a student about the homework they have due today. Construct the notification and schedule it!

```
C#

// Construct the content and schedule the toast!
new ToastContentBuilder()
    .AddArgument("action", "viewItemsDueToday")
    .AddText("ASTR 170B1")
    .AddText("You have 3 items due today!");
    .Schedule(DateTime.Now.AddSeconds(5));
```

Provide a primary key for your toast

If you want to programmatically cancel, remove, or replace the scheduled notification, you need to use the Tag property (and optionally the Group property) to provide a primary key for your notification. Then, you can use this primary key in the future to cancel, remove, or replace the notification.

To see more details on replacing/removing already delivered toast notifications, please see Quickstart: Managing toast notifications in action center (XAML).

Tag and Group combined act as a composite primary key. Group is the more generic identifier, where you can assign groups like "wallPosts", "messages", "friendRequests", etc. And then Tag should uniquely identify the notification itself from within the group. By using a generic group, you can then remove all notifications from that group by using the RemoveGroup API.

```
C#
```

```
// Construct the content and schedule the toast!
new ToastContentBuilder()
    .AddArgument("action", "viewItemsDueToday")
    .AddText("ASTR 170B1")
    .AddText("You have 3 items due today!");
    .Schedule(DateTime.Now.AddSeconds(5), toast =>
    {
        toast.Tag = "18365";
        toast.Group = "ASTR 170B1";
    });
```

Cancel scheduled notifications

To cancel a scheduled notification, you first have to retrieve the list of all scheduled notifications.

Then, find your scheduled toast matching the tag (and optionally group) you specified earlier, and call RemoveFromSchedule().

C#

```
// Create the toast notifier
ToastNotifierCompat notifier =
ToastNotificationManagerCompat.CreateToastNotifier();

// Get the list of scheduled toasts that haven't appeared yet
IReadOnlyList<ScheduledToastNotification> scheduledToasts =
notifier.GetScheduledToastNotifications();

// Find our scheduled toast we want to cancel
var toRemove = scheduledToasts.FirstOrDefault(i => i.Tag == "18365" &&
i.Group == "ASTR 170B1");
if (toRemove != null)
{
    // And remove it from the schedule
    notifier.RemoveFromSchedule(toRemove);
}
```

> **ⓘ Important**
>
> An unpackaged (lacks package identity at runtime) Win32 app must use the **ToastNotificationManagerCompat** class as seen above. If you use **ToastNotificationManager** itself, then you'll receive an element-not-found exception. All types of apps can use the **Compat** class, and it will work correctly.

Activation handling

See the send a local toast docs to learn more about handling activation. Activation of a scheduled toast notification is handled the same as activation of a local toast notification.

Adding actions, inputs, and more

See the send a local toast docs to learn more about advanced topics like actions and inputs. Actions and inputs work the same in local toasts as they do in scheduled toasts.

Custom audio on toasts

Article • 10/19/2021

Toast notifications can use custom audio, which lets your app express your brand's unique sound effects. For example, a messaging app can use their own messaging sound on their Toast notifications, so that the user can instantly know that they received a notification from the app, rather than hearing the generic notification sound.

Install UWP Community Toolkit NuGet package

In order to create notifications via code, we strongly recommend using the UWP Community Toolkit Notifications library, which provides an object model for the notification XML content. You could manually construct the notification XML, but that is error-prone and messy. The Notifications library inside UWP Community Toolkit is built and maintained by the team that owns notifications at Microsoft.

Install Microsoft.Toolkit.Uwp.Notifications from NuGet.

Add namespace declarations

```
C#

using Microsoft.Toolkit.Uwp.Notifications;
```

Add the custom audio

Windows Mobile has always supported custom audio in Toast notifications. However, Desktop only added support for custom audio in Version 1511 (build 10586). If you send a Toast that contains custom audio to a Desktop device before Version 1511, the toast will be silent. Therefore, for Desktop pre-Version 1511, you should NOT include the custom audio in your Toast notification, so that the notification will at least use the default notification sound.

Known Issue: If you're using Desktop Version 1511, the custom toast audio will only work if your app is installed via the Store. That means you cannot locally test your custom audio on Desktop before submitting to the Store - but the audio will work fine once installed from the Store. We fixed this in the Anniversary Update, so that custom audio from your locally deployed app will work correctly.

```
```

C#

```
var contentBuilder = new ToastContentBuilder()
    .AddText("New message");

bool supportsCustomAudio = true;

// If we're running on Desktop before Version 1511, do NOT include custom
audio
// since it was not supported until Version 1511, and would result in a
silent toast.
if (AnalyticsInfo.VersionInfo.DeviceFamily.Equals("Windows.Desktop")
    &&
!ApiInformation.IsApiContractPresent("Windows.Foundation.UniversalApiContrac
t", 2))
{
    supportsCustomAudio = false;
}

if (supportsCustomAudio)
{
    contentBuilder.AddAudio(new Uri("ms-
appx:///Assets/Audio/CustomToastAudio.m4a"));
}

// Send the toast
contentBuilder.Show();
```

Supported audio file types include:

- .aac
- .flac
- .m4a
- .mp3
- .wav
- .wma

Supported audio file sources:

- ms-appx:///
- ms-resource

Not supported audio file sources:

- ms-appdata
- http://, https://
- C:/, F:/, etc.

Send the notification

Sending a notification with audio is the same as sending a regular notification (just call the Show method). See Send local toast to learn more.

Toast progress bar and data binding

Article • 10/27/2022

Using a progress bar inside your toast notification allows you to convey the status of long-running operations to the user, like downloads, video rendering, exercise goals, and more.

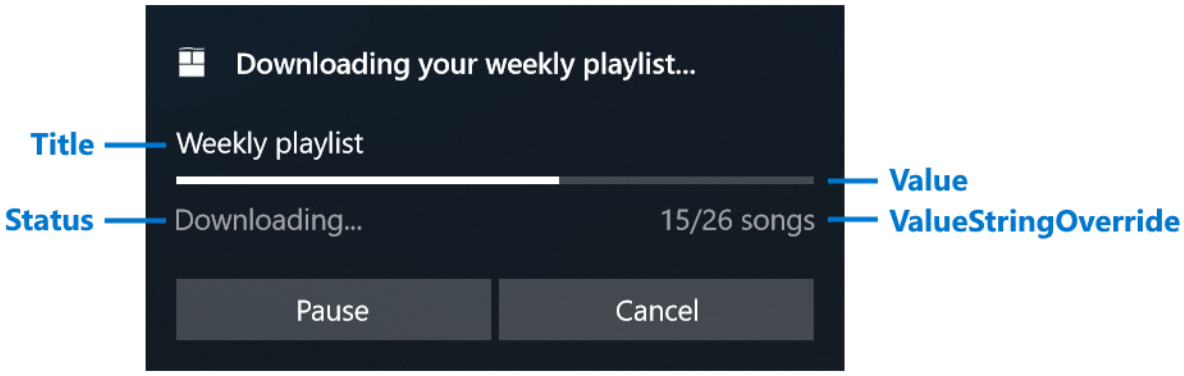
> **Important**
>
> **Requires Creators Update and 1.4.0 of Notifications library**: You must target SDK 15063 and be running build 15063 or later to use progress bars on toasts. You must use version 1.4.0 or later of the **UWP Community Toolkit Notifications NuGet library** to construct the progress bar in your toast's content.

A progress bar inside a toast can either be "indeterminate" (no specific value, animated dots indicate an operation is occurring) or "determinate" (a specific percent of the bar is filled, like 60%).

> **Important APIs**: NotificationData class, ToastNotifier.Update method, ToastNotification class

> **Note**
>
> Only Desktop supports progress bars in toast notifications. On other devices, the progress bar will be dropped from your notification.

The picture below shows a determinate progress bar with all of its corresponding properties labeled.



Property	Type	Required	Description
Title	string or BindableString	false	Gets or sets an optional title string. Supports data binding.

Property	Type	Required	Description
Value	double or AdaptiveProgressBarValue or BindableProgressBarValue	false	Gets or sets the value of the progress bar. Supports data binding. Defaults to 0. Can either be a double between 0.0 and 1.0, `AdaptiveProgressBarValue.Indeterminate`, or `new BindableProgressBarValue("myProgressValue")`.
ValueStringOverride	string or BindableString	false	Gets or sets an optional string to be displayed instead of the default percentage string. If this isn't provided, something like "70%" will be displayed.
Status	string or BindableString	true	Gets or sets a status string (required), which is displayed underneath the progress bar on the left. This string should reflect the status of the operation, like "Downloading..." or "Installing..."

Here's how you would generate the notification seen above...

Builder syntax

C#

```
new ToastContentBuilder()
    .AddText("Downloading your weekly playlist...")
    .AddVisualChild(new AdaptiveProgressBar()
    {
        Title = "Weekly playlist",
        Value = 0.6,
        ValueStringOverride = "15/26 songs",
        Status = "Downloading..."
    });
```

However, you'll need to dynamically update the values of the progress bar for it to actually be "live". This can be done by using data binding to update the toast.

Using data binding to update a toast

Using data binding involves the following steps...

1. Construct toast content that utilizes data bound fields
2. Assign a **Tag** (and optionally a **Group**) to your **ToastNotification**
3. Define your initial **Data** values on your **ToastNotification**
4. Send the toast

5. Utilize **Tag** and **Group** to update the **Data** values with new values

The following code snippet shows steps 1-4. The next snippet will show how to update the toast **Data** values.

C#

```
using Windows.UI.Notifications;
using Microsoft.Toolkit.Uwp.Notifications;

public void SendUpdatableToastWithProgress()
{
    // Define a tag (and optionally a group) to uniquely identify the
notification, in order update the notification data later;
    string tag = "weekly-playlist";
    string group = "downloads";

    // Construct the toast content with data bound fields
    var content = new ToastContentBuilder()
        .AddText("Downloading your weekly playlist...")
        .AddVisualChild(new AdaptiveProgressBar()
        {
            Title = "Weekly playlist",
            Value = new BindableProgressBarValue("progressValue"),
            ValueStringOverride = new BindableString("progressValueString"),
            Status = new BindableString("progressStatus")
        })
        .GetToastContent();

    // Generate the toast notification
    var toast = new ToastNotification(content.GetXml());

    // Assign the tag and group
    toast.Tag = tag;
    toast.Group = group;

    // Assign initial NotificationData values
    // Values must be of type string
    toast.Data = new NotificationData();
    toast.Data.Values["progressValue"] = "0.6";
    toast.Data.Values["progressValueString"] = "15/26 songs";
    toast.Data.Values["progressStatus"] = "Downloading...";

    // Provide sequence number to prevent out-of-order updates, or assign 0 to
indicate "always update"
    toast.Data.SequenceNumber = 1;

    // Show the toast notification to the user
    ToastNotificationManager.CreateToastNotifier().Show(toast);
}
```

Then, when you want to change your **Data** values, use the **Update** method to provide the new data without re-constructing the entire toast payload.

C#

```
using Windows.UI.Notifications;

public void UpdateProgress()
{
    // Construct a NotificationData object;
    string tag = "weekly-playlist";
    string group = "downloads";

    // Create NotificationData and make sure the sequence number is incremented
    // since last update, or assign 0 for updating regardless of order
    var data = new NotificationData
    {
        SequenceNumber = 2
    };

    // Assign new values
    // Note that you only need to assign values that changed. In this example
    // we don't assign progressStatus since we don't need to change it
    data.Values["progressValue"] = "0.7";
    data.Values["progressValueString"] = "18/26 songs";

    // Update the existing notification's data by using tag/group
    ToastNotificationManager.CreateToastNotifier().Update(data, tag, group);
}
```

Using the **Update** method rather than replacing the entire toast also ensures that the toast notification stays in the same position in Action Center and doesn't move up or down. It would be quite confusing to the user if the toast kept jumping to the top of Action Center every few seconds while the progress bar filled!

The **Update** method returns an enum, **NotificationUpdateResult**, which lets you know whether the update succeeded or whether the notification couldn't be found (which means the user has likely dismissed your notification and you should stop sending updates to it). We do not recommend popping another toast until your progress operation has been completed (like when the download completes).

Elements that support data binding

The following elements in toast notifications support data binding

- All properties on **AdaptiveProgress**
- The **Text** property on the top-level **AdaptiveText** elements

Update or replace a notification

Since Windows 10, you could always **replace** a notification by sending a new toast with the same **Tag** and **Group**. So what's the difference between **replacing** the toast and **updating** the toast's data?

	Replacing	**Updating**
Position in Action Center	Moves the notification to the top of Action Center.	Leaves the notification in place within Action Center.
Modifying content	Can completely change all content/layout of the toast	Can only change properties that support data binding (progress bar and top-level text)
Reappearing as popup	Can reappear as a toast popup if you leave **SuppressPopup** set to `false` (or set to true to silently send it to Action Center)	Won't reappear as a popup; the toast's data is silently updated within Action Center
User dismissed	Regardless of whether user dismissed your previous notification, your replacement toast will always be sent	If the user dismissed your toast, the toast update will fail

In general, **updating is useful for...**

- Information that frequently changes in a short period of time and doesn't require being brought to the front of the user's attention
- Subtle changes to your toast content, like changing 50% to 65%

Often times, after your sequence of updates have completed (like the file has been downloaded), we recommend replacing for the final step, because...

- Your final notification likely has drastic layout changes, like removal of the progress bar, addition of new buttons, etc
- The user might have dismissed your pending progress notification since they don't care about watching it download, but still want to be notified with a popup toast when the operation is completed

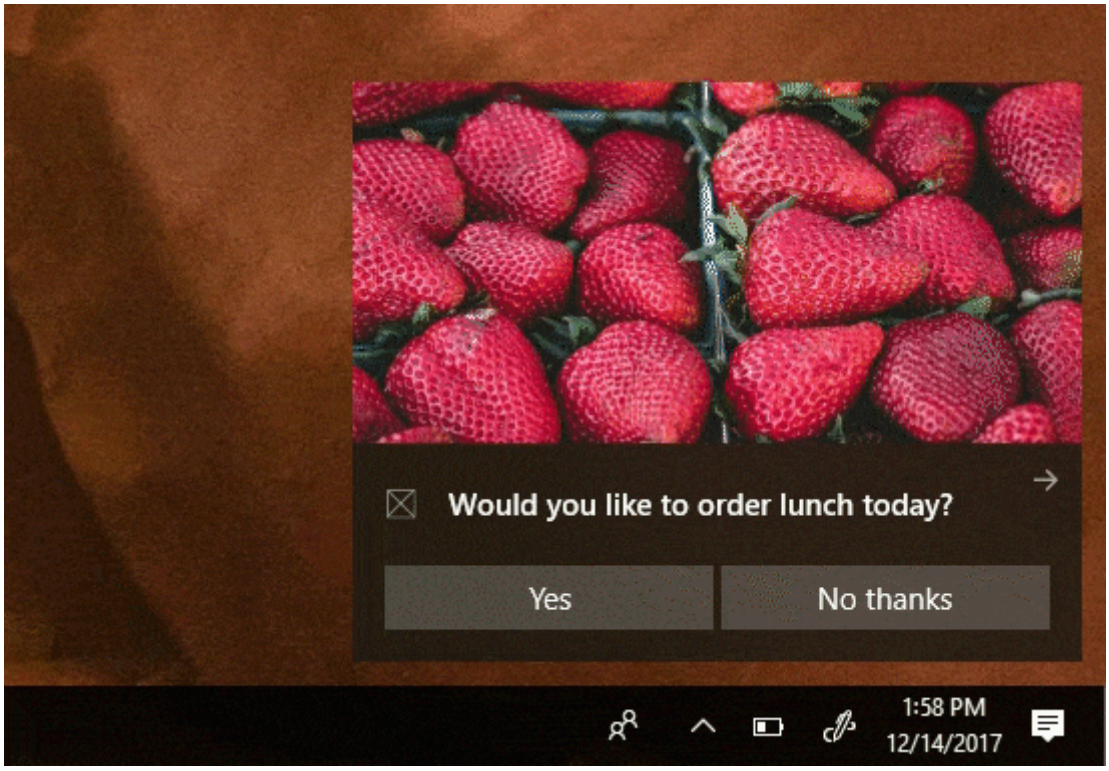
Toast with pending update activation

Article • 10/27/2022

You can use **PendingUpdate** to create multi-step interactions in your toast notifications. For example, as seen below, you can create a series of toasts where the subsequent toasts depend on responses from the previous toasts.



> **Important**
>
> **Requires Desktop Fall Creators Update and 2.0.0 of Notifications library**: You must be running Desktop build 16299 or later to see pending update work. You must use version 2.0.0 or later of the **UWP Community Toolkit Notifications NuGet library** to assign **PendingUpdate** on your buttons. **PendingUpdate** is only supported on Desktop and will be ignored on other devices.

Prerequisites

This article assumes a working knowledge of...

- Constructing toast content
- Sending a toast and handling background activation

Overview

To implement a toast that uses pending update as its after activation behavior...

1. On your toast background activation buttons, specify an **AfterActivationBehavior** of **PendingUpdate**
2. Assign a **Tag** (and optionally **Group**) when sending your toast
3. When the user clicks your button, your background task will be activated, and the toast will be kept on-screen in a pending update state
4. In your background task, send a new toast with your new content, using the same **Tag** and **Group**

Assign PendingUpdate

On your background activation buttons, set the **AfterActivationBehavior** to **PendingUpdate**. Note that this only works for buttons that have an **ActivationType** of **Background**.

Builder syntax

C#

```
new ToastContentBuilder()

    .AddText("Would you like to order lunch today?")

    .AddButton(new ToastButton("Yes", "action=orderLunch")
    {
        ActivationType = ToastActivationType.Background,

        ActivationOptions = new ToastActivationOptions()
        {
            AfterActivationBehavior =
ToastAfterActivationBehavior.PendingUpdate
        }
    });
```

Use a Tag on the notification

In order to later replace the notification, we have to assign the **Tag** (and optionally the **Group**) on the notification.

C#

```
// Create the notification
var notif = new ToastNotification(content.GetXml())
{
    Tag = "lunch"
};

// And show it
ToastNotificationManager.CreateToastNotifier().Show(notif);
```

Replace the toast with new content

In response to the user clicking your button, your background task gets triggered and you need to replace the toast with new content. You replace the toast by simply sending a new toast with the same **Tag** and **Group**.

We strongly recommend **setting the audio to silent** on replacements in response to a button click, since the user is already interacting with your toast.

C#

```
// Generate new content
ToastContent content = new ToastContent()
{
    ...

    // We disable audio on all subsequent toasts since they appear right
after the user
    // clicked something, so the user's attention is already captured
    Audio = new ToastAudio() { Silent = true }
};

// Create the new notification
var notif = new ToastNotification(content.GetXml())
{
    Tag = "lunch"
};

// And replace the old one with this one
ToastNotificationManager.CreateToastNotifier().Show(notif);
```

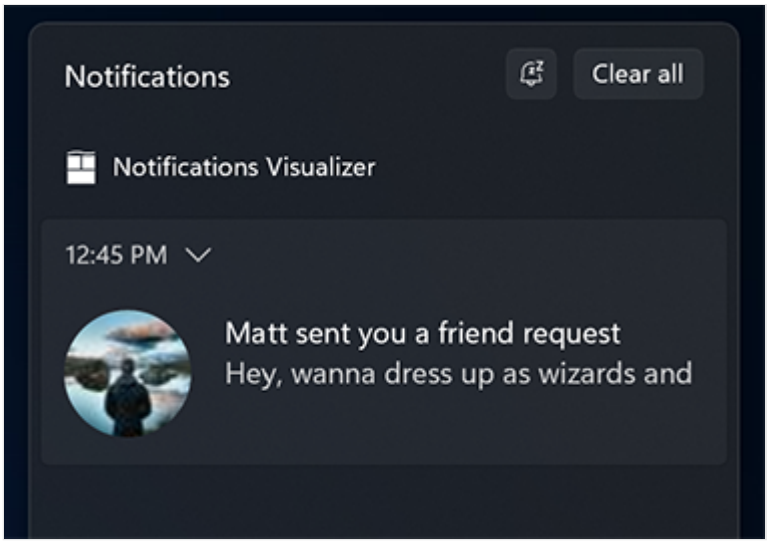
Custom timestamps on app notifications

Article • 12/13/2022

By default, the timestamp on app notifications, which is visible within Notification Center, is set to the time that the notification was sent. You can optionally override the timestamp with your own custom date and time, so that the timestamp represents the time the message/information/content was actually created, rather than the time that the notification was sent. This also ensures that your notifications appear in the correct order within Notification Center, which is sorted by time. We recommend that most apps specify a custom timestamp.

This feature is available in Windows Build 15063 and later.



> **Note**
>
> The term "toast notification" is being replaced with "app notification". These terms both refer to the same feature of Windows, but over time we will phase out the use of "toast notification" in the documentation.

To use a custom timestamp, simply assign the **displayTimestamp** property on the **toast** element of your app notification XML payload. Starting with Windows App SDK 1.2, you can add a custom timestamp to an app notification with the Microsoft.Windows.AppNotifications.Builder. For UWP apps, you can use version 1.4.0 or later of the UWP Community Toolkit Notifications NuGet library. YOu an also specify the timestamp using raw xml.

Windows App SDK

```
var builder = new AppNotificationBuilder()
    .AddText("Matt sent you a friend request")
    .AddText("Hey, wanna dress up as wizards and ride around on
hoverboards?")
    .SetTimeStamp(new DateTime(2017, 04, 15, 19, 45, 00,
DateTimeKind.Utc));
```

If you are using XML, the date must be formatted in ISO 8601.

> **Note**
>
> You can only use at most 3 decimal places on the seconds (although realistically there's no value in providing anything that granular). If you provide more, the payload will be invalid and you will receive the "New notification" notification.

Usage guidance

In general, we recommend that most apps specify a custom timestamp. This ensures that the notification's timestamp accurately represents when the message/information/content was generated, regardless of network delays, airplane mode, or the fixed interval of periodic background tasks.

For example, a news app might run a background task every 15 minutes that checks for new articles and displays notifications. Before custom timestamps, the timestamp corresponded to when the app notification was generated (therefore always in 15 minute intervals). However, now the app can set the timestamp to the time the article was actually published. Similarly, email apps and social network apps can benefit from this feature if a similar pattern of periodic pulling is used for their notifications.

Additionally, providing a custom timestamp ensures that the timestamp is correct even if the user was disconnected from the internet. For example, when the user turns their computer on and your background task runs, you can finally ensure that the timestamp on your notifications represents the time that the messages were sent, rather than the time the user turned on their computer.

Default timestamp

If you don't provide a custom timestamp, we use the time that your notification was sent.

If you sent a push notification through WNS, we use the time when the notification was received by WNS server (so any latency on delivering the notification to the device won't impact the timestamp).

If you sent a local notification, we use the time when the notification platform received the notification (which should be immediately).

Grouping toast notifications with collections

Article • 10/27/2022

Use collections to organize your app's toasts in Action Center. Collections help users locate information within Action Center more easily and allow for developers to better manage their notifications. The APIs below allow for removing, creating, and updating notification collections.

> **ⓘ Important**
>
> **Requires Creators Update**: You must target SDK 15063 and be running build 15063 or later to use toast collections. Related APIs include Windows.UI.Notifications.ToastCollection, and Windows.UI.Notifications.ToastCollectionManager

You can see the example below with a messaging app that separates the notifications based on the chat group; each title (Comp Sci 160A Project Chat, Direct Messages, Lacrosse Team Chat) is a separate collection. Notice how the notifications are distinctly grouped as if they were from a separate app, even though they are all notifications from the same app. If you are looking for a more subtle way to organize your notifications,

see toast headers.

Creating collections

When creating each collection, you are required to provide a display name and an icon, which are displayed inside Action Center as part of the collection's title, as shown in the image above. Collections also require a launch argument to help the app navigate to the right location within the app when the collection's title is clicked on by the user.

Create a collection

C#

```
// Create a toast collection
public async void CreateToastCollection()
{
    string displayName = "Work Email";
    string launchArg = "NavigateToWorkEmailInbox";
    Uri icon = new Windows.Foundation.Uri("ms-
appx:///Assets/workEmail.png");

    // Constructor
    ToastCollection workEmailToastCollection = new ToastCollection(
        "MyToastCollection",
        displayName,
        launchArg,
        icon);

    // Calls the platform to create the collection
    await
ToastNotificationManager.GetDefault().GetToastCollectionManager().SaveToastC
ollectionAsync(workEmailToastCollection);
}
```

Sending notifications to a collection

We will cover sending notifications from three different toast pipelines: local, scheduled, and push. For each of these examples we will be creating a sample toast to send with the code immediately below, then we will focus on how to add the toast to a collection via each pipeline.

Construct the toast content:

```
C#

// Construct the content
var content = new ToastContentBuilder()
    .AddText("Adam sent a message to the group")
    .GetToastContent();
```

Send a toast to a collection

```
C#

// Create the toast
ToastNotification toast = new ToastNotification(content.GetXml());

// Get the collection notifier
var notifier = await
ToastNotificationManager.GetDefault().GetToastNotifierForToastCollectionIdAs
ync("MyToastCollection");

// And show the toast
notifier.Show(toast);
```

Add a scheduled toast to a collection

```
C#

// Create scheduled toast from XML above
ScheduledToastNotification scheduledToast = new
ScheduledToastNotification(content.GetXml(),
DateTimeOffset.Now.AddSeconds(10));

// Get notifier
var notifier = await
ToastNotificationManager.GetDefault().GetToastNotifierForToastCollectionIdAs
ync("MyToastCollection");

// Add to schedule
notifier.AddToSchedule(scheduledToast);
```

Send a push toast to a collection

For push toasts, you need to add the X-WNS-CollectionId header to the POST message.

C#

```
// Add header to HTTP request
request.Headers.Add("X-WNS-CollectionId", collectionId);
```

Managing collections

Create the toast collection manager

For the rest of the code snippets in this 'Managing Collections' section we will be using the collectionManager below.

C#

```
ToastCollectionManger collectionManager =
ToastNotificationManager.GetDefault().GetToastCollectionManager();
```

Get all collections

C#

```
IReadOnlyList<ToastCollection> collections = await
collectionManager.FindAllToastCollectionsAsync();
```

Get the number of collections created

C#

```
int toastCollectionCount = (await
collectionManager.FindAllToastCollectionsAsync()).Count;
```

Remove a collection

C#

```
await collectionManager.RemoveToastCollectionAsync("MyToastCollection");
```

Update a collection

You can update collections by creating a new collection with the same ID and saving the new instance of the collection.

C#

```
string displayName = "Updated Display Name";
string launchArg = "UpdatedLaunchArgs";
Uri icon = new Windows.Foundation.Uri("ms-
appx:///Assets/updatedPicture.png");

// Construct a new toast collection with the same collection id
ToastCollection updatedToastCollection = new ToastCollection(
    "MyToastCollection",
    displayName,
    launchArg,
    icon);

// Calls the platform to update the collection by saving the new instance
await collectionManager.SaveToastCollectionAsync(updatedToastCollection);
```

Managing toasts within a collection

Group and tag properties

The group and tag properties together uniquely identify a notification within a collection. Group (and Tag) serves as a composite primary key (more than one identifier) to identify your notification. For example, if you want to remove or replace a notification, you have to be able to specify *what notification* you want to remove/replace; you do that by specifying the Tag and Group. An example is a messaging app. The developer could use the conversation ID as the Group, and the message ID as the Tag.

Remove a toast from a collection

You can remove individual toasts using the tag and group IDs, or clear all toasts in a collection.

C#

```
// Get the history
var collectionHistory = await
ToastNotificationManager.GetDefault().GetHistoryForToastCollectionAsync("MyT
oastCollection");

// Remove toast
collectionHistory.Remove(tag, group);
```

Clear all toasts within a collection

C#

```
// Get the history
var collectionHistory = await
ToastNotificationManager.GetDefault().GetHistoryForToastCollectionAsync("MyT
oastCollection");

// Remove toast
collectionHistory.Clear();
```

Collections in Notifications Visualizer

You can use the Notifications Visualizer tool to help design your collections. Follow the steps below:

- Click on the gear icon in the bottom right corner.
- Select 'Toast collections'.
- Above the preview of the toast, there is a 'Toast Collection' dropdown menu. Select manage collections.
- Click 'Add collection', fill out the details for the collection, and save.
- You can add more collections, or click off of the manage collections box to return to the main screen.
- Select the collection you want to add the toast to from the 'Toast Collection' dropdown menu.
- When you fire the toast, it will be added to the appropriate collection in Action Center.

Other details

The toast collections that you create will also be reflected in the user's notification settings. Users can toggle the settings for each individual collection to turn these subgroups on or off. If notifications are turned off at the top level for the app, then all

collections notifications will be turned off as well. In addition, each collection will by default show 3 notifications in Action Center, and the user can expand it to show up to 20 notifications.

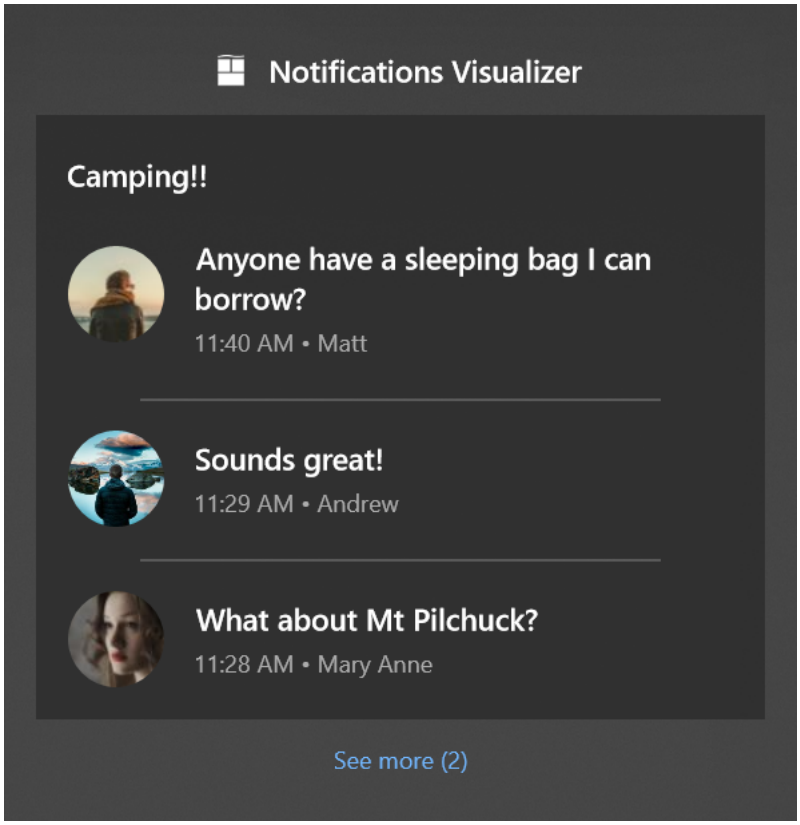
Toast headers

Article • 10/27/2022

You can visually group a set of related notifications inside Action Center by using a toast header on your notifications.

> **Important**
>
> **Requires Desktop Creators Update and 1.4.0 of Notifications library**: You must be running Desktop build 15063 or later to see toast headers. You must use version 1.4.0 or later of the **UWP Community Toolkit Notifications NuGet library** to construct the header in your toast's content. Headers are only supported on Desktop.

As seen below, this group conversation is unified under a single header, "Camping!!". Each individual message in the conversation is a separate toast notification sharing the same toast header.



You can also choose to visually group your notifications by category too, like flight reminders, package tracking, and more.

Add a header to a toast

Here's how you add a header to a toast notification.

> **Note**
>
> Headers are only supported on Desktop. Devices that don't support headers will simply ignore the header.

Builder syntax

C#

```
new ToastContentBuilder()
    .AddHeader("6289", "Camping!!", "action=openConversation&id=6289")
    .AddText("Anyone have a sleeping bag I can borrow?");
```

In summary...

1. Add the **Header** to your **ToastContent**
2. Assign the required **Id**, **Title**, and **Arguments** properties
3. Send your notification (learn more)
4. On another notification, use the same header **Id** to unify them under the header. The **Id** is the only property used to determine whether the notifications should be grouped, meaning the **Title** and **Arguments** can be different. The **Title** and **Arguments** from the most recent notification within a group are used. If that notification gets removed, then the **Title** and **Arguments** falls back to the next most recent notification.

Handle activation from a header

Headers are clickable by users, so that the user can click the header to find out more from your app.

Therefore, apps can provide **Arguments** on the header, similar to the launch arguments on the toast itself.

Activation is handled identical to normal toast activation, meaning you can retrieve these arguments in the **OnActivated** method of `App.xaml.cs` just like you do when the user clicks the body of your toast or a button on your toast.

C#

```
protected override void OnActivated(IActivatedEventArgs e)
{
    // Handle toast activation
    if (e is ToastNotificationActivatedEventArgs)
    {
        // Arguments specified from the header
        string arguments = (e as
ToastNotificationActivatedEventArgs).Argument;
    }
}
```

Additional info

The header visually separates and groups notifications. It doesn't change any other logistics about the maximum number of notifications an app can have (20) and the first-in-first-out behavior of the notifications list.

The order of notifications within headers are as follows... For a given app, the most recent notification from the app (and the entire header group if part of a header) will appear first.

The **Id** can be any string you choose. There are no length or character restrictions on any of the properties in **ToastHeader**. The only constraint is that your entire XML toast content cannot be larger than 5 KB.

Creating headers doesn't change the number of notifications shown inside Action Center before the "See more" button appears (this number is 3 by default and can be configured by the user for each app in system Settings for notifications).

Clicking on the header, just like clicking on the app title, does not clear any notifications belonging to this header (your app should use the toast APIs to clear the relevant notifications).

Notification listener: Access all notifications

Article • 10/27/2022

The notification listener provides access to a user's notifications. Smartwatches and other wearables can use the notification listener to send the phone's notifications to the wearable device. Home automation apps can use notification listener to perform specific actions when notifications are received, such as making the lights blink when you receive a call.

> **ⓘ Important**
>
> **Requires Anniversary Update**: You must target SDK 14393 and be running build 14393 or later to use Notification Listener.

> **Important APIs**: UserNotificationListener class, UserNotificationChangedTrigger class

Enable the listener by adding the User Notification capability

To use the notification listener, you must add the User Notification Listener capability to your app manifest.

1. In Visual Studio, in the Solution Explorer, double click your `Package.appxmanifest` file to open the manifest designer.
2. Open the Capabilities tab.
3. Check the **User Notification Listener** capability.

Check whether the listener is supported

If your app supports older versions of Windows 10, you need to use the ApiInformation class to check whether the listener is supported. If the listener isn't supported, avoid executing any calls to the listener APIs.

C#

```
if
(ApiInformation.IsTypePresent("Windows.UI.Notifications.Management.UserNotif
```

```
icationListener"))
{
    // Listener supported!
}

else
{
    // Older version of Windows, no Listener
}
```

Requesting access to the listener

Since the listener allows access to the user's notifications, users must give your app permission to access their notifications. During your app's first-run experience, you should request access to use the notification listener. If you want, you can show some preliminary UI that explains why your app needs access to the user's notifications before you call RequestAccessAsync, so that the user understands why they should allow access.

C#

```
// Get the listener
UserNotificationListener listener = UserNotificationListener.Current;

// And request access to the user's notifications (must be called from UI
thread)
UserNotificationListenerAccessStatus accessStatus = await
listener.RequestAccessAsync();

switch (accessStatus)
{
    // This means the user has granted access.
    case UserNotificationListenerAccessStatus.Allowed:

        // Yay! Proceed as normal
        break;

    // This means the user has denied access.
    // Any further calls to RequestAccessAsync will instantly
    // return Denied. The user must go to the Windows settings
    // and manually allow access.
    case UserNotificationListenerAccessStatus.Denied:

        // Show UI explaining that listener features will not
        // work until user allows access.
        break;

    // This means the user closed the prompt without
    // selecting either allow or deny. Further calls to
    // RequestAccessAsync will show the dialog again.
```

```
    case UserNotificationListenerAccessStatus.Unspecified:

        // Show UI that allows the user to bring up the prompt again
        break;
}
```

The user can revoke access at any time via Windows Settings. Therefore, your app should always check the access status via the GetAccessStatus method before executing code that uses the notification listener. If the user revokes access, the APIs will silently fail rather than throwing an exception (for example, the API to get all notifications will simply return an empty list).

Access the user's notifications

With the notification listener, you can get a list of the user's current notifications. Simply call the GetNotificationsAsync method, and specify the type of notifications you want to get (currently, the only type of notifications supported are toast notifications).

C#

```
// Get the toast notifications
IReadOnlyList<UserNotification> notifs = await
listener.GetNotificationsAsync(NotificationKinds.Toast);
```

Displaying the notifications

Each notification is represented as a UserNotification, which provides information about the app that the notification is from, the time the notification was created, the notification's ID, and the notification itself.

C#

```
public sealed class UserNotification
{
    public AppInfo AppInfo { get; }
    public DateTimeOffset CreationTime { get; }
    public uint Id { get; }
    public Notification Notification { get; }
}
```

The AppInfo property provides the info you need to display the notification.

> ⓘ Note

We recommend surrounding all your code for processing a single notification in a try/catch, in case an unexpected exception occurs when you are capturing a single notification. You shouldn't completely fail to display other notifications just because of an issue with one specific notification.

C#

```
// Select the first notification
UserNotification notif = notifs[0];

// Get the app's display name
string appDisplayName = notif.AppInfo.DisplayInfo.DisplayName;

// Get the app's logo
BitmapImage appLogo = new BitmapImage();
RandomAccessStreamReference appLogoStream =
notif.AppInfo.DisplayInfo.GetLogo(new Size(16, 16));
await appLogo.SetSourceAsync(await appLogoStream.OpenReadAsync());
```

The content of the notification itself, such as the notification text, is contained in the Notification property. This property contains the visual portion of the notification. (If you are familiar with sending notifications on Windows, you will notice that the Visual and Visual.Bindings properties in the Notification object correspond to what developers send when popping a notification.)

We want to look for the toast binding (for error-proof code, you should check that the binding isn't null). From the binding, you can obtain the text elements. You can choose to display as many text elements as you would like. (Ideally, you should display them all.) You can choose to treat the text elements differently; for example, treat the first one as title text, and subsequent elements as body text.

C#

```
// Get the toast binding, if present
NotificationBinding toastBinding =
notif.Notification.Visual.GetBinding(KnownNotificationBindings.ToastGeneric)
;

if (toastBinding != null)
{
    // And then get the text elements from the toast binding
    IReadOnlyList<AdaptiveNotificationText> textElements =
toastBinding.GetTextElements();

    // Treat the first text element as the title text
    string titleText = textElements.FirstOrDefault()?.Text;

    // We'll treat all subsequent text elements as body text,
```

```
    // joining them together via newlines.
    string bodyText = string.Join("\n", textElements.Skip(1).Select(t =>
t.Text));
}
```

Remove a specific notification

If your wearable or service allows the user to dismiss notifications, you can remove the actual notification so the user doesn't see it later on their phone or PC. Simply provide the notification ID (obtained from the UserNotification object) of the notification you'd like to remove:

C#

```
// Remove the notification
listener.RemoveNotification(notifId);
```

Clear all notifications

The UserNotificationListener.ClearNotifications method clears all the user's notifications. Use this method with caution. You should only clear all notifications if your wearable or service displays ALL notifications. If your wearable or service only displays certain notifications, when the user clicks your "Clear notifications" button, the user is only expecting those specific notifications to be removed; however, calling the ClearNotifications method would actually cause all the notifications, including ones that your wearable or service wasn't displaying, to be removed.

C#

```
// Clear all notifications. Use with caution.
listener.ClearNotifications();
```

Background task for notification added/dismissed

A common way to enable an app to listen to notifications is to set up a background task, so that you can know when a notification was added or dismissed regardless of whether your app is currently running.

Thanks to the single process model added in the Anniversary Update, adding background tasks is fairly simple. In your main app's code, after you have obtained the user's access to Notification Listener and obtained access to run background tasks by calling UserNotificationListener.Current.RequestAccessAsync and BackgroundExecutionManager.RequestAccessAsync respectively, simply register a new background task, and set the UserNotificationChangedTrigger using the Toast notification kind.

C#

```
// TODO: Request/check Listener access via
UserNotificationListener.Current.RequestAccessAsync

// TODO: Request/check background task access via
BackgroundExecutionManager.RequestAccessAsync

// If background task isn't registered yet
if (!BackgroundTaskRegistration.AllTasks.Any(i =>
i.Value.Name.Equals("UserNotificationChanged")))
{
    // Specify the background task
    var builder = new BackgroundTaskBuilder()
    {
        Name = "UserNotificationChanged"
    };

    // Set the trigger for Listener, listening to Toast Notifications
    builder.SetTrigger(new
UserNotificationChangedTrigger(NotificationKinds.Toast));

    // Register the task
    builder.Register();
}
```

Then, in your App.xaml.cs, override the OnBackgroundActivated method if you haven't yet, and use a switch statement on the task name to determine which of your many background task triggers was invoked.

C#

```
protected override async void
OnBackgroundActivated(BackgroundActivatedEventArgs args)
{
    var deferral = args.TaskInstance.GetDeferral();

    switch (args.TaskInstance.Task.Name)
    {
        case "UserNotificationChanged":
            // Call your own method to process the new/removed notifications
            // The next section of documentation discusses this code
```

```
            await MyWearableHelpers.SyncNotifications();
            break;
    }

    deferral.Complete();
}
```

The background task is simply a "shoulder tap": it doesn't provide any information about which specific notification was added or removed. When your background task is triggered, you should sync the notifications on your wearable so that they reflect the notifications in the platform. This ensures that if your background task fails, notifications on your wearable can still be recovered the next time your background task executes.

`SyncNotifications` is a method you implement; the next section shows how.

Determining which notifications were added and removed

In your `SyncNotifications` method, to determine which notifications have been added or removed (syncing notifications with your wearable), you have to calculate the delta between your current notification collection, and the notifications in the platform.

C#

```
// Get all the current notifications from the platform
IReadOnlyList<UserNotification> userNotifications = await
listener.GetNotificationsAsync(NotificationKinds.Toast);

// Obtain the notifications that our wearable currently has displayed
IList<uint> wearableNotificationIds = GetNotificationsOnWearable();

// Copy the currently displayed into a list of notification ID's to be
removed
var toBeRemoved = new List<uint>(wearableNotificationIds);

// For each notification in the platform
foreach (UserNotification userNotification in userNotifications)
{
    // If we've already displayed this notification
    if (wearableNotificationIds.Contains(userNotification.Id))
    {
        // We want to KEEP it displayed, so take it out of the list
        // of notifications to remove.
        toBeRemoved.Remove(userNotification.Id);
    }

    // Otherwise it's a new notification
    else
```

```
    {
        // Display it on the Wearable
        SendNotificationToWearable(userNotification);
    }
}

// Now our toBeRemoved list only contains notification ID's that no longer
exist in the platform.
// So we will remove all those notifications from the wearable.
foreach (uint id in toBeRemoved)
{
    RemoveNotificationFromWearable(id);
}
```

Foreground event for notification added/dismissed

> **ⓘ Important**
>
> Known issue: In builds before Build 17763 / October 2018 Update / Version 1809, The foreground event will cause a CPU loop and/or didn't work. If you need support on those earlier builds, use the background task instead.

You can also listen to notifications from an in-memory event handler...

C#

```
// Subscribe to foreground event
listener.NotificationChanged += Listener_NotificationChanged;

private void Listener_NotificationChanged(UserNotificationListener sender,
UserNotificationChangedEventArgs args)
{
    // Your code for handling the notification
}
```

How to fix delays in the background task

When testing your app, you might notice that the background task is sometimes delayed and doesn't trigger for several minutes. To fix the delay, prompt the user to go to the system settings -> System -> Battery -> Battery usage by app, find your app in the list, select it, and set it to be "Always allowed in background." After this, the

background task should always be triggered within around a second of the notification being received.

Notification mirroring

Article • 10/27/2022

Notification mirroring, powered by Action Center in the Cloud, allows you to see your phone's notifications on your PC.

> **Important**
>
> **Requires Anniversary Update**: You must be running build 14393 or later to see notification mirroring work. If you would like to opt your app out of notification mirroring, you must target SDK 14393 to access the mirroring APIs.

With notification mirroring and Cortana, users can receive and act on their phone's notifications (Windows Mobile and Android) from the convenience of their PC. As a developer, you don't have to do anything to enable notification mirroring, mirroring automatically works! Clicking buttons on the mirrored toast, like message quick replies, will be routed back to the phone, invoking you background task or launching your foreground app.

Developers get two great benefits from notification mirroring: The mirrored notifications result in more user engagement with your service, and they also help users discover your Microsoft Store desktop app! Your users might not even know that you have an awesome Windows app available for their Windows 10 desktop. When users receive the mirrored notification from their phone, users can click the toast notification to be taken to the Microsoft Store, where they can install your Windows app.

Mirroring works with both Windows Phone and Android. Users need to be logged into Cortana on both their phone and desktop for notification mirroring to work.

What if the app is installed on both devices?

If the user already has your app on their PC, we will automatically mute the mirrored phone notification so that they don't see duplicate notifications. Mirrored notifications will be auto-muted based on the following criteria...

1. An app on the PC exists with either the **same display name or the same PFN** (Package Family Name)
2. That PC app has sent a toast notification

If the PC app hasn't sent a toast yet, we'll still show the phone notifications, since chances are, the user hasn't actually launched the PC app yet).

How to opt out of mirroring

Windows app developers, enterprises, and users can choose to disable notification mirroring.

> ⓘ **Note**
>
> Disabling mirroring will also disable **Universal Dismiss**.

As a developer, opt out an individual notification

You occasionally might have a device-specific notification that you don't want to be mirrored to other devices. You can prevent a specific notification from being mirrored by setting the **Mirroring** property on the toast notification. Currently, this mirroring property can only be set on local notifications (it can not be specified when sending a WNS push notification).

Known Issue: Retrieving the Mirroring property via the `ToastNotificationHistory.GetHistory()` API's will always return the default value (**Allowed**) rather than the option you specified. Don't worry, everything is functional - it's only retrieving the value that's broken.

C#

```
var toast = new ToastNotification(xml)
{
    // Disable mirroring of this notification
    Mirroring = NotificationMirroring.Disabled
};

ToastNotificationManager.CreateToastNotifier().Show(toast);
```

As a developer, opt out completely

Some developers might choose to completely opt their app out of notification mirroring. While we believe that all apps would benefit from mirroring, we make it easy to opt out. Just call the following method once, and your app will be opted out. For example, you can place this call in your app's constructor inside `App.xaml.cs`...

C#

```
public App()
{
    this.InitializeComponent();
    this.Suspending += OnSuspending;

    // Disable notification mirroring for entire app

ToastNotificationManager.ConfigureNotificationMirroring(NotificationMirrorin
g.Disabled);
}
```

As an enterprise, how do I opt out?

Enterprises can choose to completely disable notification mirroring. To do so, they simply edit the Group Policy to turn off notification mirroring.

As a user, how do I opt out?

Users are able to opt out on individual apps, or completely opt out by disabling the feature. You may not want a specific app's notifications mirrored to your desktop, so you can simply disable that specific app. You can find these options in Cortana's settings on both your phone and PC.

Universal Dismiss

Article • 10/27/2022

Universal Dismiss, powered by Action Center in the Cloud, means that when you dismiss a notification from one device, the same notification on your other devices is also dismissed.

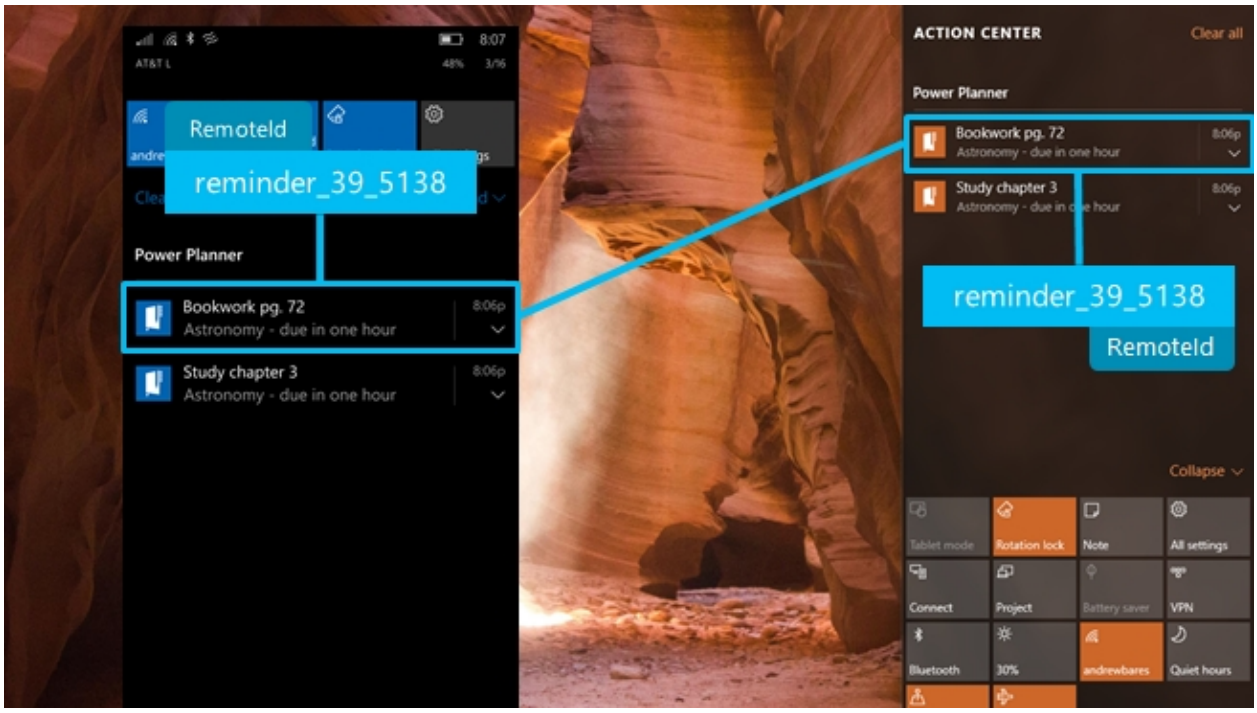
> ⓘ **Important**
>
> **Requires Anniversary Update**: You must target SDK 14393 and be running build 14393 or later to use Universal Dismiss.

The common example of this scenario is calendar reminders... you have a calendar app on both of your devices... you get a reminder on your phone and desktop... you click dismiss on your desktop... thanks to Universal Dismiss, the reminder on your phone is also dismissed! **Enabling Universal Dismiss only requires one line of code!**

In this scenario, the key fact is that **the same app is installed on multiple devices**, meaning that **each device is already receiving notifications**. A calendar app is the iconic example, since you typically have the same calendar app installed on both your Windows PC and your phone, and each instance of the app already sends you reminders on each device. By adding support for Universal Dismiss, those instances of the same reminders can be linked across devices.

How to enable Universal Dismiss

As a developer, enabling Universal Dismiss is extremely easy. You simply need to provide an ID that allows us to link each notification across devices, so that when the user dismisses a notification from one device, the corresponding linked notification is dismissed from the other device.



> **RemoteId**: An identifier that uniquely identifies a notification *across devices*.

t only takes one line of code to add RemoteId, enabling support for Universal Dismiss! How you generate your RemoteId is up to you - however, you need to make sure that it uniquely identifies your notification across devices, and that the same identifier can be generated from different instances of your app running on different devices.

For example, in my homework planner app, I generate my RemoteId by saying that it is of type "reminder", and then I include the online account ID and the online identifier of the homework item. I can consistently generate the exact same RemoteId, regardless of which device is sending the notification, since these online IDs are shared across the devices.

C#

```
var toast = new ScheduledToastNotification(content.GetXml(), startTime);

// If the RemoteId property is present
if
(ApiInformation.IsPropertyPresent(typeof(ScheduledToastNotification).FullNam
e, nameof(ScheduledToastNotification.RemoteId)))
{
    // Assign the RemoteId to add support for Universal Dismiss
    toast.RemoteId = $"reminder_{account.AccountId}_{homework.Identifier}"
}

ToastNotificationManager.CreateToastNotifier().AddToSchedule(toast);
```

The following code runs on both my phone and desktop app, meaning that the notification on both devices will have the same RemoteId.

That's all you have to do! When the user dismisses (or clicks on) a notification, we'll check if it has a RemoteId, and if so, we'll fan out a dismiss of that RemoteId across all the user's devices.

Known Issue: Retrieving the **RemoteId** via the `ToastNotificationHistory.GetHistory()` API's will always return empty string rather than the **RemoteId** you specified. Don't worry, everything is functional - it's only retrieving the value that's broken.

> ⓘ **Note**
>
> If the user or enterprise disables **notification mirroring** for your app (or completely disables notification mirroring), then Universal Dismiss will not work, since we do not have your notifications in the cloud.

Supported devices

Since the Anniversary Update, Universal Dismiss is supported on Windows Mobile and Windows Desktop. Universal Dismiss works both directions, between PC-PC, PC-Phone, and Phone-Phone.

Badge notifications for Windows apps

Article • 02/27/2025

A notification badge conveys summary or status information specific to your app. They can be numeric (1-99) or one of a set of system-provided glyphs. Examples of information best conveyed through a badge include network connection status in an online game, user status in a messaging app, number of unread mails in a mail app, and number of new posts in a social media app.

Notification badges appear on your app's taskbar icon and in the lower-right corner of its start tile, regardless of whether the app is running. Badges can be displayed on all tile sizes.

> **Note**
>
> You cannot provide your own badge image; only system-provided badge images can be used.

Numeric badges

Expand table

Value	Badge	XML
A number from 1 to 99. A value of 0 is equivalent to the glyph value "none" and will clear the badge.		`<badge value="1"/>`
Any number greater than 99.		`<badge value="100"/>`

Glyph badges

Instead of a number, a badge can display one of a non-extensible set of status glyphs.

Expand table

Status	Glyph	XML
none	(No badge shown.)	`<badge value="none"/>`

Status	Glyph	XML
activity		`<badge value="activity"/>`
alarm		`<badge value="alarm"/>`
alert		`<badge value="alert"/>`
attention		`<badge value="attention"/>`
available		`<badge value="available"/>`
away		`<badge value="away"/>`
busy		`<badge value="busy"/>`
error		`<badge value="error"/>`
newMessage		`<badge value="newMessage"/>`
paused		`<badge value="paused"/>`
playing		`<badge value="playing"/>`
unavailable		`<badge value="unavailable"/>`

Create a badge

These examples show you how to create a badge update.

Create a numeric badge

C#

```
private void setBadgeNumber(int num)
{

    // Get the blank badge XML payload for a badge number
    XmlDocument badgeXml =

BadgeUpdateManager.GetTemplateContent(BadgeTemplateType.BadgeNumber);

    // Set the value of the badge in the XML to our number
    XmlElement badgeElement = badgeXml.SelectSingleNode("/badge") as
XmlElement;
    badgeElement.SetAttribute("value", num.ToString());

    // Create the badge notification
    BadgeNotification badge = new BadgeNotification(badgeXml);

    // Create the badge updater for the application
    BadgeUpdater badgeUpdater =
        BadgeUpdateManager.CreateBadgeUpdaterForApplication();

    // And update the badge
    badgeUpdater.Update(badge);

}
```

Create a glyph badge

C#

```
private void updateBadgeGlyph()
{
    string badgeGlyphValue = "alert";

    // Get the blank badge XML payload for a badge glyph
    XmlDocument badgeXml =
        BadgeUpdateManager.GetTemplateContent(BadgeTemplateType.BadgeGlyph);

    // Set the value of the badge in the XML to our glyph value
    Windows.Data.Xml.Dom.XmlElement badgeElement =
        badgeXml.SelectSingleNode("/badge") as
Windows.Data.Xml.Dom.XmlElement;
    badgeElement.SetAttribute("value", badgeGlyphValue);

    // Create the badge notification
    BadgeNotification badge = new BadgeNotification(badgeXml);

    // Create the badge updater for the application
```

```
    BadgeUpdater badgeUpdater =
        BadgeUpdateManager.CreateBadgeUpdaterForApplication();

    // And update the badge
    badgeUpdater.Update(badge);

}
```

Clear a badge

C#

```
private void clearBadge()
{
    BadgeUpdateManager.CreateBadgeUpdaterForApplication().Clear();
}
```

Windows Push Notification Services (WNS) overview

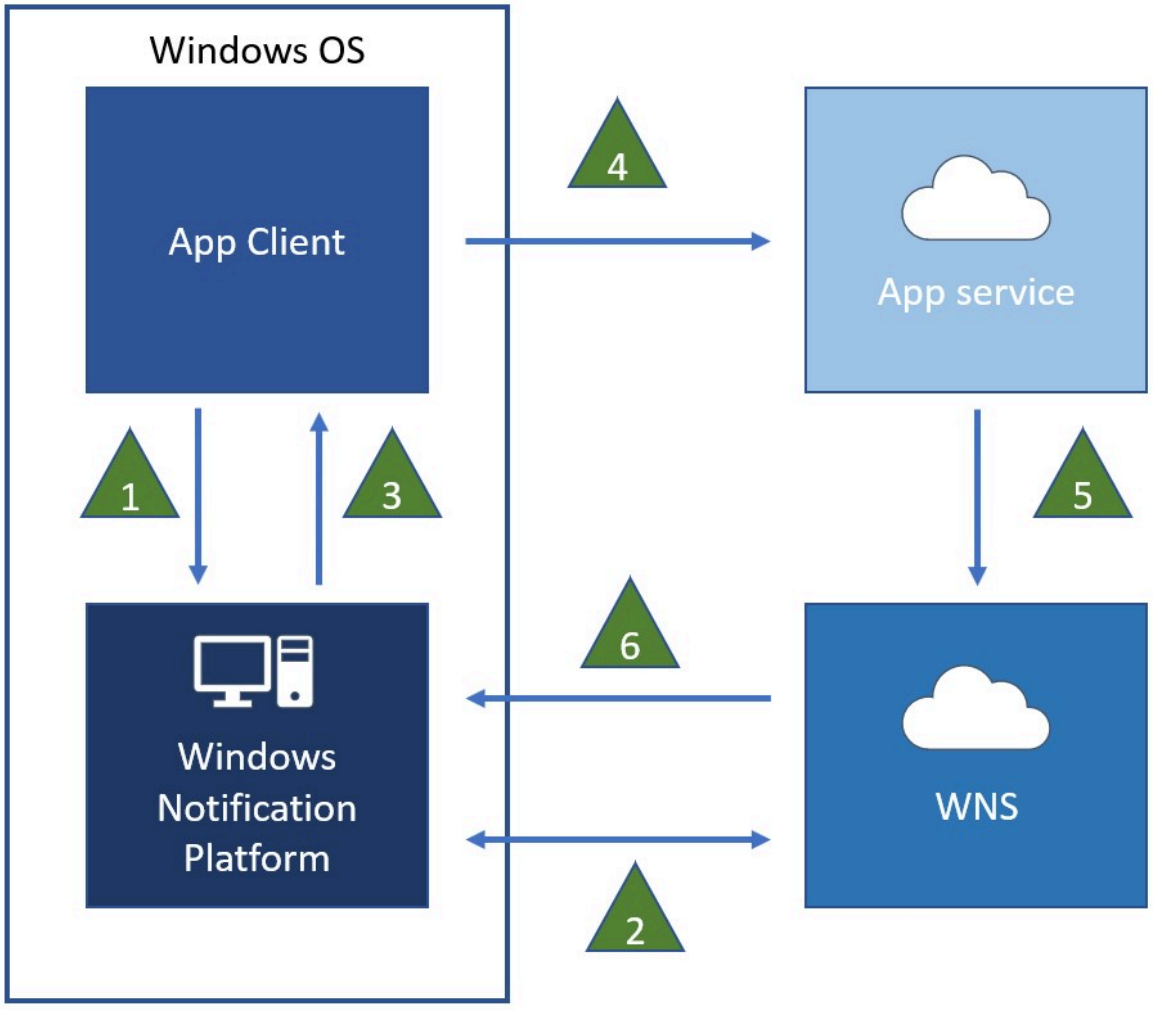
Article • 11/27/2024

The Windows Push Notification Services (WNS) enable third-party developers to send toast, tile, badge, and raw updates from their own cloud service. This provides a mechanism to deliver new updates to your users in a power-efficient and dependable way.

How it works

The following diagram shows the complete data flow for sending a push notification. It involves these steps:

1. Your app requests a push notification channel from WNS.
2. Windows asks WNS to create a notification channel. This channel is returned to the calling device in the form of a Uniform Resource Identifier (URI).
3. The notification channel URI is returned by WNS to your app.
4. Your app sends the URI to your own cloud service. You then store the URI on your own cloud service so that you can access the URI when you send notifications. The URI is an interface between your own app and your own service; it's your responsibility to implement this interface with safe and secure web standards.
5. When your cloud service has an update to send, it notifies WNS using the channel URI. This is done by issuing an HTTP POST request, including the notification payload, over Secure Sockets Layer (SSL). This step requires authentication.
6. WNS receives the request and routes the notification to the appropriate device.



Registering your app and receiving the credentials for your cloud service

Before you can send notifications using WNS, your app must be registered with the Store Dashboard, as described here.

Requesting a notification channel

When an app that is capable of receiving push notifications runs, it must first request a notification channel through the **CreatePushNotificationChannelForApplicationAsync**. For a full discussion and example code, see How to request, create, and save a notification channel. This API returns a channel URI that is uniquely linked to the calling application and its tile, and through which all notification types can be sent.

After the app has successfully created a channel URI, it sends it to its cloud service, together with any app-specific metadata that should be associated with this URI.

Important notes

- We do not guarantee that the notification channel URI for an app will always remain the same. We advise that the app requests a new channel every time it runs and updates its service when the URI changes. The developer should never modify the channel URI and should consider it as a black-box string. At this time, channel URIs expire after 30 days. If your Windows 10 app will periodically renew its channel in the background then you can download the Push and periodic notifications sample for Windows 8.1 and re-use its source code and/or the pattern it demonstrates.
- The interface between the cloud service and the client app is implemented by you, the developer. We recommend that the app go through an authentication process with its own service and transmit data over a secure protocol such as HTTPS.
- It is important that the cloud service always ensures that the channel URI uses the domain "notify.windows.com". The service should never push notifications to a channel on any other domain. If the callback for your app is ever compromised, a malicious attacker could submit a channel URI to spoof WNS. Without inspecting the domain, your cloud service could potentially disclose information to this attacker unknowingly. The subdomain of the channel URI is subject to change and should not be considered when validating the channel URI.
- If your cloud service attempts to deliver a notification to an expired channel, WNS will return response code 410. In response to that code, your service should no longer attempt to send notifications to that URI.

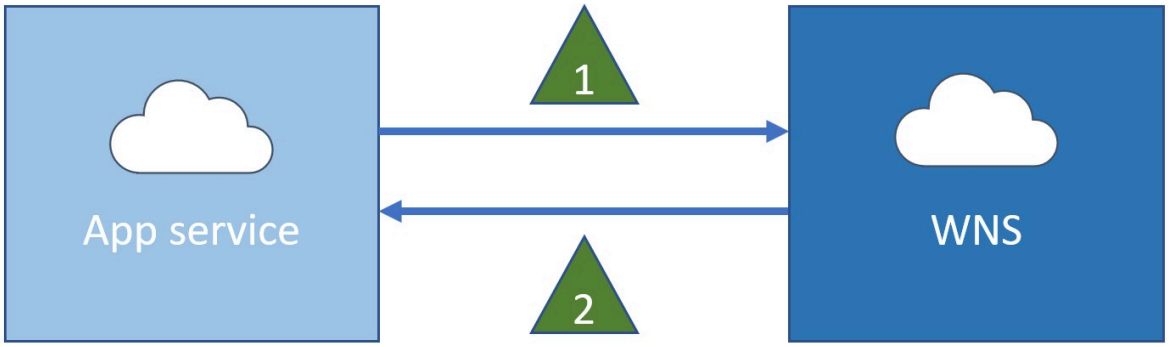
Authenticating your cloud service

To send a notification, the cloud service must be authenticated through WNS. The first step in this process occurs when you register your app with the Microsoft Store Dashboard. During the registration process, your app is given a Package security identifier (SID) and a secret key. This information is used by your cloud service to authenticate with WNS.

The WNS authentication scheme is implemented using the client credentials profile from the OAuth 2.0 protocol. The cloud service authenticates with WNS by providing its credentials (Package SID and secret key). In return, it receives an access token. This access token allows a cloud service to send a notification. The token is required with every notification request sent to the WNS.

At a high level, the information chain is as follows:

1. The cloud service sends its credentials to WNS over HTTPS following the OAuth 2.0 protocol. This authenticates the service with WNS.
2. WNS returns an access token if the authentication was successful. This access token is used in all subsequent notification requests until it expires.



In the authentication with WNS, the cloud service submits an HTTP request over Secure Sockets Layer (SSL). The parameters are supplied in the "application/x-www-for-urlencoded" format. Supply your Package SID in the "client_id" field and your secret key in the "client_secret" field as shown in the following example. For syntax details, see the access token request reference.

> **Note**
>
> This is just an example, not cut-and-paste code that you can successfully use in your own code.

HTTP

```
POST /accesstoken.srf HTTP/1.1
Content-Type: application/x-www-form-urlencoded
Host: https://login.live.com
Content-Length: 211

grant_type=client_credentials&client_id=ms-app%3a%2f%2fS-1-15-2-2972962901-2322836549-3722629029-1345238579-3987825745-2155616079-650196962&client_secret=Vex8L9WOFZuj95euaLrvSH7XyoDhLJc7&scope=notify.windows.com
```

The WNS authenticates the cloud service and, if successful, sends a response of "200 OK". The access token is returned in the parameters included in the body of the HTTP response, using the "application/json" media type. After your service has received the access token, you are ready to send notifications.

The following example shows a successful authentication response, including the access token. For syntax details, see Push notification service request and response headers.

HTTP

```
HTTP/1.1 200 OK
Cache-Control: no-store
Content-Length: 422
Content-Type: application/json

{
    "access_token":"EgAcAQMAAAAALYAAY/c+Huwi3Fv4Ck10UrKNmtxRO6Njk2MgA=",
    "token_type":"bearer"
}
```

Important notes

- The OAuth 2.0 protocol supported in this procedure follows draft version V16.
- The OAuth Request for Comments (RFC) uses the term "client" to refer to the cloud service.
- There might be changes to this procedure when the OAuth draft is finalized.
- The access token can be reused for multiple notification requests. This allows the cloud service to authenticate just once to send many notifications. However, when the access token expires, the cloud service must authenticate again to receive a new access token.

Sending a notification

Using the channel URI, the cloud service can send a notification whenever it has an update for the user.

The access token described above can be reused for multiple notification requests; the cloud server is not required to request a new access token for every notification. If the access token has expired, the notification request will return an error. We recommended that you do not try to re-send your notification more than once if the access token is rejected. If you encounter this error, you will need to request a new access token and resend the notification. For the exact error code, see Push notification response codes.

1. The cloud service makes an HTTP POST to the channel URI. This request must be made over SSL and contains the necessary headers and the notification payload. The authorization header must include the acquired access token for authorization.

An example request is shown here. For syntax details, see Push notification response codes.

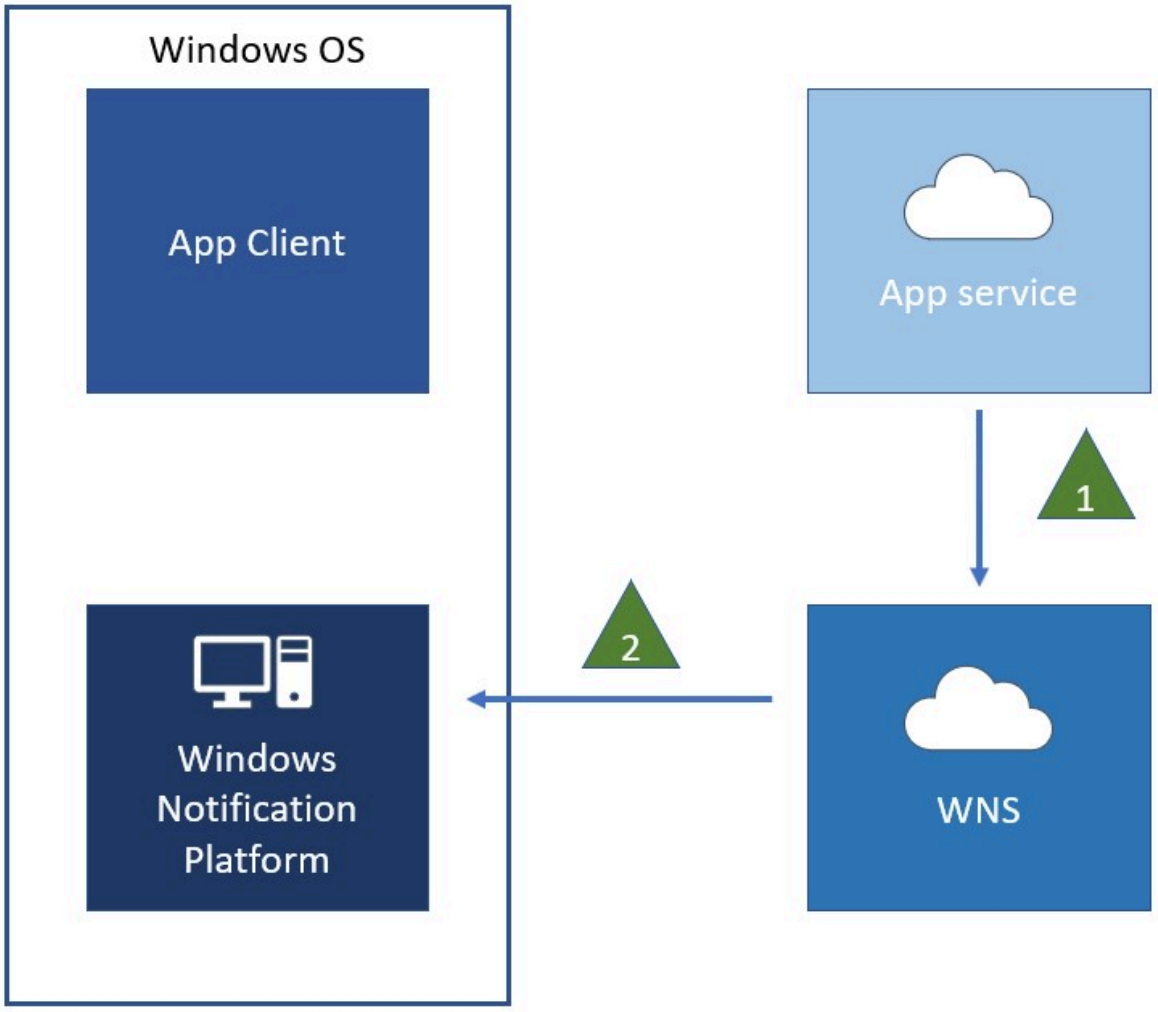
For details on composing the notification payload, see Quickstart: Sending a push notification. The payload of a tile, toast, or badge push notification is supplied as XML content that adheres to their respective defined Adaptive tiles schema or Legacy tiles schema. The payload of a raw notification does not have a specified structure. It is strictly app-defined.

```HTTP
 POST https://cloud.notify.windows.com/?
token=AQE%bU%2fSjZOCvRjjpILow%3d%3d HTTP/1.1
 Content-Type: text/xml
 X-WNS-Type: wns/tile
 Authorization: Bearer
EgAcAQMAAAAALYAAY/c+Huwi3Fv4Ck10UrKNmtxRO6Njk2MgA=
 Host: cloud.notify.windows.com
 Content-Length: 24

 <body>
 ....
```

2. WNS responds to indicate that the notification has been received and will be delivered at the next available opportunity. However, WNS does not provide end-to-end confirmation that your notification has been received by the device or application.

This diagram illustrates the data flow:



Important notes

- WNS does not guarantee the reliability or latency of a notification.
- Notifications should never include confidential, sensitive, or personal data.
- To send a notification, the cloud service must first authenticate with WNS and receive an access token.
- An access token only allows a cloud service to send notifications to the single app for which the token was created. One access token cannot be used to send notifications across multiple apps. Therefore, if your cloud service supports multiple apps, it must provide the correct access token for the app when pushing a notification to each channel URI.
- When the device is offline, by default WNS will store one of each notification type (tile, badge, toast) for each channel URI and no raw notifications.
- In scenarios where the notification content is personalized to the user, WNS recommends that the cloud service immediately send those updates when those are received. Examples of this scenario include social media feed updates, instant communication invitations, new message notifications, or alerts. As an alternative, you can have scenarios in which the same generic update is frequently delivered to

a large subset of your users; for example, weather, stock, and news updates. WNS guidelines specify that the frequency of these updates should be at most one every 30 minutes. The end user or WNS may determine more frequent routine updates to be abusive.
- Windows Notification Platform maintains a periodic data connection with WNS to keep the socket alive and healthy. If there are no applications requesting or using notification channels then the socket will not be created.

Expiration of tile and badge notifications

By default, tile and badge notifications expire three days after being downloaded. When a notification expires, the content is removed from the tile or queue and is no longer shown to the user. It's a best practice to set an expiration (using a time that makes sense for your app) on all tile and badge notifications so that your tile's content doesn't persist longer than it is relevant. An explicit expiration time is essential for content with a defined lifespan. This also assures the removal of stale content if your cloud service stops sending notifications, or if the user disconnects from the network for an extended period.

Your cloud service can set an expiration for each notification by setting the X-WNS-TTL HTTP header to specify the time (in seconds) that your notification will remain valid after it is sent. For more information, see Push notification service request and response headers.

For example, during a stock market's active trading day, you can set the expiration for a stock price update to twice that of your sending interval (such as one hour after receipt if you are sending notifications every half-hour). As another example, a news app might determine that one day is an appropriate expiration time for a daily news tile update.

Push notifications and battery saver

Battery saver extends battery life by limiting background activity on the device. Windows 10 lets the user set battery saver to turn on automatically when the battery drops below a specified threshold. When battery saver is on, the receipt of push notifications is disabled to save energy. But there are a couple exceptions to this. The following Windows 10 battery saver settings (found in the **Settings** app) allow your app to receive push notifications even when battery saver is on.

- **Allow push notifications from any app while in battery saver**: This setting lets all apps receive push notifications while battery saver is on. Note that this setting

applies only to Windows 10 for desktop editions (Home, Pro, Enterprise, and Education).

- **Always allowed**: This setting lets specific apps run in the background while battery saver is on - including receiving push notifications. This list is maintained manually by the user.

There is no way to check the state of these two settings, but you can check the state of battery saver. In Windows 10, use the **EnergySaverStatus** property to check battery saver state. Your app can also use the **EnergySaverStatusChanged** event to listen for changes to battery saver.

If your app depends heavily on push notifications, we recommend notifying users that they may not receive notifications while battery saver is on and to make it easy for them to adjust **battery saver settings**. Using the battery saver settings URI scheme in Windows 10, `ms-settings:batterysaver-settings`, you can provide a convenient link to the Settings app.

> **Tip**
>
> When notifying the user about battery saver settings, we recommend providing a way to suppress the message in the future. For example, the `dontAskMeAgainBox` checkbox in the following example persists the user's preference in **LocalSettings**.

Here's an example of how to check whether battery saver is turned on in Windows 10. This example notifies the user and launches the Settings app to **battery saver settings**. The `dontAskAgainSetting` lets the user suppress the message if they don't want to be notified again.

C#

```
using System;
using Windows.UI.Xaml;
using Windows.UI.Xaml.Controls;
using Windows.UI.Xaml.Navigation;
using Windows.System;
using Windows.System.Power;
...
...
async public void CheckForEnergySaving()
{
   //Get reminder preference from LocalSettings
   bool dontAskAgain;
   var localSettings =
Windows.Storage.ApplicationData.Current.LocalSettings;
   object dontAskSetting = localSettings.Values["dontAskAgainSetting"];
```

```
    if (dontAskSetting == null)
    {  // Setting does not exist
       dontAskAgain = false;
    }
    else
    {  // Retrieve setting value
       dontAskAgain = Convert.ToBoolean(dontAskSetting);
    }

    // Check if battery saver is on and that it's okay to raise dialog
    if ((PowerManager.EnergySaverStatus == EnergySaverStatus.On)
          && (dontAskAgain == false))
    {
       // Check dialog results
       ContentDialogResult dialogResult = await saveEnergyDialog.ShowAsync();
       if (dialogResult == ContentDialogResult.Primary)
       {
          // Launch battery saver settings (settings are available only when
a battery is present)
          await Launcher.LaunchUriAsync(new Uri("ms-settings:batterysaver-
settings"));
       }

       // Save reminder preference
       if (dontAskAgainBox.IsChecked == true)
       {  // Don't raise dialog again
          localSettings.Values["dontAskAgainSetting"] = "true";
       }
    }
}
```

C++/WinRT

```
#include <winrt/Windows.Foundation.h>
#include <winrt/Windows.Storage.h>
#include <winrt/Windows.System.h>
#include <winrt/Windows.System.Power.h>
#include <winrt/Windows.UI.Xaml.h>
#include <winrt/Windows.UI.Xaml.Controls.h>
#include <winrt/Windows.UI.Xaml.Navigation.h>
using namespace winrt;
using namespace winrt::Windows::Foundation;
using namespace winrt::Windows::Storage;
using namespace winrt::Windows::System;
using namespace winrt::Windows::System::Power;
using namespace winrt::Windows::UI::Xaml;
using namespace winrt::Windows::UI::Xaml::Controls;
using namespace winrt::Windows::UI::Xaml::Navigation;
...
winrt::fire_and_forget CheckForEnergySaving()
{
    // Get reminder preference from LocalSettings.
    bool dontAskAgain{ false };
```

```
    auto localSettings = ApplicationData::Current().LocalSettings();
    IInspectable dontAskSetting =
localSettings.Values().Lookup(L"dontAskAgainSetting");
    if (!dontAskSetting)
    {
        // Setting doesn't exist.
        dontAskAgain = false;
    }
    else
    {
        // Retrieve setting value
        dontAskAgain = winrt::unbox_value<bool>(dontAskSetting);
    }

    // Check whether battery saver is on, and whether it's okay to raise
dialog.
    if ((PowerManager::EnergySaverStatus() == EnergySaverStatus::On) &&
(!dontAskAgain))
    {
        // Check dialog results.
        ContentDialogResult dialogResult = co_await
saveEnergyDialog().ShowAsync();
        if (dialogResult == ContentDialogResult::Primary)
        {
            // Launch battery saver settings
            // (settings are available only when a battery is present).
            co_await Launcher::LaunchUriAsync(Uri(L"ms-
settings:batterysaver-settings"));
        }

        // Save reminder preference.
        if (dontAskAgainBox().IsChecked())
        {
            // Don't raise the dialog again.
            localSettings.Values().Insert(L"dontAskAgainSetting",
winrt::box_value(true));
        }
    }
}
```

This is the XAML for the ContentDialog featured in this example.

XAML

```
<ContentDialog x:Name="saveEnergyDialog"
               PrimaryButtonText="Open battery saver settings"
               SecondaryButtonText="Ignore"
               Title="Battery saver is on.">
   <StackPanel>
      <TextBlock TextWrapping="WrapWholeWords">
         <LineBreak/><Run>Battery saver is on and you may
          not receive push notifications.</Run><LineBreak/>
         <LineBreak/><Run>You can choose to allow this app to work normally
```

```
            while in battery saver, including receiving push notifications.
</Run>
            <LineBreak/>
        </TextBlock>
        <CheckBox x:Name="dontAskAgainBox" Content="OK, got it."/>
    </StackPanel>
</ContentDialog>
```

Quickstart: Sending a push notification (XAML)

Article • 10/25/2021

Your cloud server can send a push notification to your app through the Windows Push Notification Services (WNS). This procedure applies to tile, toast, badge, and raw push notifications.

Objective: To create and send a tile, toast, badge, or raw push notification.

Prerequisites

To understand this topic or to use the code it provides, you will need:

- A familiarity with HTTP communications.
- An authenticated cloud server. For more information, see How to authenticate with the Windows Push Notification Service (WNS).
- A registered channel over which your cloud server can communicate with your app. For more information, see How to request, create, and save a notification channel.
- An existing tile for your app, defined in your app's manifest, to receive the notification (unless you're sending a raw notification). For more information, see Quickstart: Creating a default tile using the Microsoft Visual Studio manifest editor.
- A familiarity with XML and its manipulation through Document Object Model (DOM) APIs.
- In the case of raw notifications, your app must be configured to receive raw notifications. For more information, see Quickstart: Intercepting push notifications for running apps and Quickstart: Creating and registering a raw notification background task.

Instructions

1. Include the necessary namespace references

The examples given in this topic can be used as-is, but require that your code include these namespace references:

```
C#
```

```
using System.Net;
using System.IO;
using System.Runtime.Serialization;
using System.Runtime.Serialization.Json;
using System.Web;
using System.Text;
```

2. Create an HTTP POST request

The `uri` parameter is the channel Uniform Resource Identifier (URI) requested by the app and passed to the cloud server. For more information, see How to request, create, and save a notification channel.

C#

```
HttpWebRequest request = HttpWebRequest.Create(uri) as HttpWebRequest;
request.Method = "POST";
```

3. Add the required headers

There are four required headers that must be included in all push notifications: X-WNS-Type, Content-Type, Content-Length, and Authorization.

- The X-WNS-Type header specifies whether this is a tile, toast, badge, or raw notification.
- The Content-Type is set depending on the value of the X-WNS-Type.
- The Content-Length gives the size of the included notification payload.
- The Authorization header specifies the authentication credential that allows you to send a push notification to this user over this channel.

The *accessToken* parameter of the Authorization header specifies the access token, stored on the server, that was received from WNS when the cloud server requested authentication. Without the access token, your notification will be rejected.

For a complete list of possible headers, see Push notification service request and response headers.

C#

```
request.Headers.Add("X-WNS-Type", notificationType);
request.ContentType = contentType;
request.Headers.Add("Authorization", String.Format("Bearer {0}",
accessToken.AccessToken));
```

4. Add the prepared content

As far as the HTTP request is concerned, the XML content of the notification is a data blob in the request body. For instance, no verification is made that the XML matches the X-WNS-Type specification. The content is specified as an XML payload and here is added to the request as a stream of bytes.

C#

```
byte[] contentInBytes = Encoding.UTF8.GetBytes(xml);

using (Stream requestStream = request.GetRequestStream())
    requestStream.Write(contentInBytes, 0, contentInBytes.Length);
```

5. Listen for a response from WNS that acknowledges receipt of the notification

> **Note**
>
> You will never receive a delivery confirmation for a notification, just an acknowledgment that it was received by WNS.

C#

```
using (HttpWebResponse webResponse = (HttpWebResponse)request.GetResponse())
    return webResponse.StatusCode.ToString();
```

6. Handle WNS response codes

There are many response codes that your app service can receive when it sends a notification. Some of these response codes are more common than others and can be easily dealt with in a catch block.

C#

```
catch (WebException webException)
{
    HttpStatusCode status =
((HttpWebResponse)webException.Response).StatusCode;
```

HttpStatusCode.Unauthorized: The access token you presented has expired. Get a new one and then try sending your notification again. Because your cached access token

expires after 24 hours, you can expect to get this response from WNS at least once a day. We recommend that you implement a maximum retry policy.

```
C#
```

```
    if (status == HttpStatusCode.Unauthorized)
    {
        GetAccessToken(secret, sid);
        return PostToWns(uri, xml, secret, sid, notificationType,
contentType);
    }
```

HttpStatusCode.Gone / HttpStatusCode.NotFound: The channel URI is no longer valid. Remove this channel from your database to prevent further attempts to send notification to it. The next time this user launches your app, request a new WNS channel. Your app should detect that its channel has changed, which should trigger the app to send the new channel URI to your app server. For more information, see How to request, create, and save a notification channel.

```
C#
```

```
    else if (status == HttpStatusCode.Gone || status ==
HttpStatusCode.NotFound)
    {
        return "";
    }
```

HttpStatusCode.NotAcceptable: This channel is being throttled by WNS. Implement a retry strategy that exponentially reduces the amount of notifications being sent in order to prevent being throttled again. Also, rethink scenarios that are causing your notifications to be throttled. You will provide a richer user experience by limiting the notifications you send to those that add true value.

```
C#
```

```
    else if (status == HttpStatusCode.NotAcceptable)
    {
        return "";
    }
```

Other response codes: WNS responded with a less common response code. Log this code to assist in debugging. See Push notification service request and response headers for a full list of WNS response codes.

```
C#
```

```
    else
    {
        string[] debugOutput = {
                                        status.ToString(),
                                        webException.Response.Headers["X-WNS-
Debug-Trace"],
                                        webException.Response.Headers["X-WNS-
Error-Description"],
                                        webException.Response.Headers["X-WNS-Msg-
ID"],
                                        webException.Response.Headers["X-WNS-
Status"]
                                    };
        return string.Join(" | ", debugOutput);
    }
```

7. Encapsulate the code into a single function

The following example packages the code given in the preceding steps into a single function. This function composes the HTTP POST request that contains a notification to be sent to WNS. By changing the value of the *type* parameter and adjusting additional headers, this code can be used for toast, tile, badge, or raw push notifications. You can use this function as part of your cloud server code.

Note that the error handling in this function includes the situation where the access token has expired. In this case, it calls another cloud server function that re-authenticates with WNS to obtain a new access token. It then makes a new call to the original function.

C#

```
// Post to WNS
public string PostToWns(string secret, string sid, string uri, string xml,
string notificationType, string contentType)
{

The following shows example content for an HTTP POST request for a toast push notification.

C#

```
POST https://db3.notify.windows.com/?
token=AgUAAADCQmTg7OMlCg%2fK0K8rBPcBqHuy%2b1rTSNPMuIzF6BtvpRdT7DM4j%2fs%2bNN
m8z5l1QKZMtyjByKW5uXqb9V7hIAeA3i8FoKR%2f49ZnGgyUkAhzix%2fuSuasL3jalk7562F4Bp
w%3d HTTP/1.1
Authorization: Bearer EgAaAQMAAAAEgAAACoAAPzCGedIbQb9vRfPF2Lxy3K//QZB79mLTgK
X-WNS-RequestForStatus: true
X-WNS-Type: wns/toast
Content-Type: text/xml
Host: db3.notify.windows.com
Content-Length: 196

<toast launch="">
  <visual lang="en-US">
    <binding template="ToastImageAndText01">
      <image id="1" src="World" />
      <text id="1">Hello</text>
    </binding>
  </visual>
</toast>
```

The following shows an example HTTP response, sent to the cloud server by WNS in response to the HTTP POST request.

```
C#

HTTP/1.1 200 OK
Content-Length: 0
X-WNS-DEVICECONNECTIONSTATUS: connected
X-WNS-STATUS: received
X-WNS-MSG-ID: 3CE38FF109E03A74
X-WNS-DEBUG-TRACE: DB3WNS4011534
```

Summary

In this Quickstart, you composed an HTTP POST request to send to WNS. WNS, in turn, delivers the notification to your app. By this point, you have registered your app, authenticated your cloud server with WNS, created XML content to define your notification, and sent that notification from your server to your app.

WNS Notification Priorities

Article • 03/17/2023

By setting a notification's priority with a simple header to WNS POST messages, you can control how notifications are delivered in battery sensitive situations.

Power on Windows

As more users are working only on battery powered devices, minimizing power usage has become a standard requirement for all apps. If apps consume more energy than the value they provide, users might uninstall the apps. While the Windows operating system reduces power usage on the battery where possible, it is the app's responsibility to work efficiently.

WNS priorities is one way to move non-critical work off the battery. The WNS priorities tell the system which notifications should be delivered instantly and which can wait until the device is plugged into a power source. With these hints, the system can deliver the notifications the exact time they are the most valuable to both the user and the app.

Power modes on the device

Every Windows device operates through a variety of power modes (battery, battery saver, and charge), and users expect different behaviors from apps in different power modes. When the device is on, all notifications should be delivered. In battery saver mode, only the most important notifications should be delivered. While the device is plugged in, sync or non-time critical operations can be completed.

Windows does not know which notifications are important to any user or app, so the system relies totally on apps to set the right priority for their notifications.

Priorities

There are four priorities available for an app to use when sending push notifications. The priority is set on individual notifications, allowing you to choose which notifications need to be delivered instantly (for example, an IM message) and which ones can wait (for example, contact photo updates).

The priorities are:

Expand table

Priority	User Override	Description	Example
High	Yes – user can block all notifications from an app OR can prevent an app from being throttled in battery saver mode.	The most important notifications that must be delivered right away in any circumstance when the device can receive notifications. Things like VoIP calls or critical alerts that should wake the device fall into this category.	VoIP calls, time-critical alerts
Medium	Yes – user can block all notifications from an app OR can prevent an app from being throttled in battery saver mode.	These are things that are not as important, things that don't need to happen right away, but users would be annoyed if they are not running in the background.	Secondary Email account sync, live tile updates.
Low	Yes – user can block all notifications from an app OR can prevent an app from being throttled in battery saver mode.	Notifications that only make sense when the user is using the device or when background activity makes sense. These are cached and not processed until the user signs in or plugs in their device.	Contact status (online/offline)

Note that many apps will have notifications of different priority throughout their lifecycle. Since the priority is set on a per-notification basis, this isn't an issue. A VoIP app can send a high priority notification for an incoming call and then follow it up with a low priority one when a contact comes online.

Setting the priority

Setting the priority on the notification request is done through an additional header on the POST request, `X-WNS-PRIORITY`. This is an integer value between 1 and 4 which maps to a priority:

Expand table

Priority Name	X-WNS-PRIORITY Value	Default for:
High	1	Toasts
Medium	2	Tiles and Badges
Low	3	Raw

To be backward compatible, setting a priority is not required. In case an app doesn't set the priority of their notifications, the system will provide a default priority. The defaults are shown in the chart above and match the behavior of existing versions of Windows.

Detailed listing of desktop behavior

If you are shipping your app across many different SKUs of Windows, it is normally best to follow the chart in the above section.

More specific recommended behaviors for each priority are listed below. This is not a guarantee that each device will work exactly according to the chart. OEMs are free to configure the behavior differently, but most are close to this chart.

Expand table

Device State	PRIORITY: High	PRIORITY: Medium	PRIORITY: Low	PRIORITY: Very Low
Screen On OR plugged in	Deliver	Deliver	Deliver	Deliver
Screen Off AND on battery	Deliver	If user exempted: deliver Else: cache	If user exempted: deliver Else: cache *	Cache
Battery Saver enabled	If user exempted: deliver Else: cache	If user exempted: deliver Else: cache	If user exempted: deliver Else: cache	Cache
On battery + battery saver enabled + screen off	If user exempted: deliver Else: cache	If user exempted: deliver Else: cache	If user exempted: deliver Else: cache	Cache

Note that low priority notifications will be delivered by default for screen off and battery only for Windows Phone based devices. This is to maintain compatibility with preexisting MPNS policy. Also note that the fourth and fifth rows are the same, just calling out different scenarios.

To exempt an app in battery saver, users must go to the "Battery Usage by App" in Settings and select "Allow the app to run background tasks." This user selection exempts the app from battery saver for high, medium, and low priority notifications. You can also call BackgroundExecutionManager API to programmatically ask for the user's permission.

Enterprise Firewall Configurations to Support WNS Traffic

Article • 10/04/2021

Background

Many enterprises use firewalls to block unwanted network traffic and ports; unfortunately, this can also block important things like Windows Notification Service communications. This means all notifications sent through WNS will be dropped under certain network configurations. To avoid this, network admins can add the list of approved WNS FQDNs or VIPs to their exemption list to allow the WNS traffic to pass through the firewall.

Proxy Support

> **Note**
>
> WNS Push Notifications *may not* support proxies. There are many different proxy setups and environments, and not all configurations are guaranteed work with WNS. For best results, the connection to WNS must be a direct connection, however, VPN interfaces can be used.

We welcome any feedback about proxy support. Please direct your feedback to https://aka.ms/windowsappsdk and file an issue for tracking interest in proxy support for WNS. Feel free to add the "area-Notifications" label to your issue for quicker visibility with the notifications team.

What information should be added to the allowlist

Below is a list that contains the FQDNs, VIPs, and IP address ranges used by the Windows Notification Service.

> **Important**

We strongly suggest that you allow list by FQDN, because these will not change. If you allow list by FQDN, you do not need to also allow the IP address ranges.

> **ⓘ Important**
>
> The IP address ranges will change periodically; because of this, they are not included on this page. If you want to see the list of IP ranges, you can download the file from Download Center: **Windows Notification Service (WNS) VIP and IP Ranges**. Please check back regularly to make sure you have the most up-to-date information.

FQDNs, VIPs, IPs, and Ports

Regardless of the method you choose from below, you'll need to allow network traffic to the listed destinations through **port 443**. Each of the elements in the following XML document is explained in the table that follows it (in Terms and Notations). The IP ranges were intentionally left out of this document to encourage you to use only the FQDNs as the FQDNs will remain constant. However, you can download the XML file containing the complete list from Download Center: Windows Notification Service (WNS) VIP and IP Ranges. New VIPs or IP ranges will be **effective one week after they are uploaded**.

XML

```
<?xml version="1.0" encoding="UTF-8"?>
<WNSPublicIpAddresses xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xmlns:xsd="http://www.w3.org/2001/XMLSchema">
    <!-- This file contains the FQDNs, VIPs, and IP address ranges used by
the Windows Notification Service. A new text file will be uploaded every
time a new VIP or IP range is released in production.  Please copy the below
information and perform the necessary changes on your site. Endpoints in
CloudService nodes are used for cloud services to send notifications to WNS.
Endpoints in Client nodes are used by devices to receive notifications from
WNS. -->
    <CloudServiceDNS>
    <DNS FQDN="*.notify.windows.com"/>
    </CloudServiceDNS>
    <ClientDNS>
        <DNS FQDN="*.wns.windows.com"/>
        <DNS FQDN="*.notify.live.net"/>
    </ClientDNS>
    <CloudServiceIPs>
        <IpRange Subnet=""/>
        <!-- See the file in Download Center for the complete list of IP
ranges -->
```

```
    </CloudServiceIPs>
    <ClientIPsIPv4>
        <IpRange Subnet=""/>
        <!-- See the file in Download Center for the complete list of IP
ranges -->
    </ClientIPsIPv4>
    <IdentityServiceDNS>
        <DNS FQDN="login.microsoftonline.com"/>
        <DNS FQDN="login.live.com"/>
    </IdentityServiceDNS>
</WNSPublicIpAddresses>
```

Terms and notations

Below are explanations on the notations and elements used in the above XML snippet.

Expand table

Term	Explanation
Dot-decimal notation (i.e. 64.4.28.0/26)	Dot-decimal notation is a way to describe the range of IP addresses. For example, 64.4.28.0/26 means the first 26 bits of 64.4.28.0 are constant, while the last 6 bits are variable. In this case, the IPv4 range is 64.4.28.0 - 64.4.28.63.
ClientDNS	These are the Fully-Qualified Domain Name (FQDN) filters for the client devices (Windows PCs, desktops) receiving notifications from WNS. These must be allowed through the firewall in order for WNS clients to use the WNS Functionality. It is recommended to allow-list by the FQDNs instead of the IP/VIP ranges, since these will never change.
ClientIPsIPv4	These are the IPv4 addresses of the servers accessed by client devices (Windows PCs, desktops) receiving notifications from WNS.
CloudServiceDNS	These are the Fully-Qualified Domain Name (FQDN) filters for the WNS servers your cloud service will talk to send notifications to WNS. These must be allowed through the firewall in order for services to send WNS notifications. It is recommended to allow-list by the FQDNs instead of the IP/VIP ranges, since these will never change.
CloudServiceIPs	CloudServiceIPs are the IPv4 addresses of the servers used for cloud services to send notifications to WNS

Microsoft Push Notifications Service (MPNS) public IP ranges

If you are using the legacy notification service, MPNS, the IP address ranges that you will need to add to the allow list are available from Download Center: Microsoft Push Notifications Service (MPNS) Public IP ranges.

Code generated by the push notification wizard

Article • 06/24/2021

By using a wizard in Visual Studio, you can generate push notifications from a mobile service that was created with Azure Mobile Services. The Visual Studio wizard generates code to help you get started. This topic explains how the wizard modifies your project, what the generated code does, how to use this code, and what you can do next to get the most out of push notifications. See Windows Push Notification Services (WNS) overview.

How the wizard modifies your project

The push notification wizard modifies your project in the following ways:

- Adds a reference to Mobile Services Managed Client (MobileServicesManagedClient.dll). Not applicable to JavaScript projects.
- Adds a file in a subfolder under services, and names the file push.register.cs, push.register.vb, push.register.cpp, or push.register.js.
- Creates a channels table on the database server for the mobile service. The table contains information that's required to send push notifications to app instances.
- Creates scripts for four functions: delete, insert, read and update.
- Creates a script with a custom API, notifyallusers.js, which sends a push notification to all clients.
- Adds a declaration to your App.xaml.cs, App.xaml.vb, or App.xaml.cpp file, or adds a declaration to a new file, service.js, for JavaScript projects. The declaration declares a MobileServiceClient object, which contains the information that's required to connect to the mobile service. You can access this MobileServiceClient object, which is named *MyServiceName*Client, from any page in your app by using the name App.*MyServiceName*Client.

The services.js file contains the following code:

JavaScript

```
var <mobile-service-name>Client = new
Microsoft.WindowsAzure.MobileServices.MobileServiceClient(
                "https://<mobile-service-name>.azure-mobile.net/",
                "<your client secret>");
```

Registration for push notifications

In push.register.*, the UploadChannel method registers the device to receive push notifications. The Store tracks installed instances of your app and provides the push notification channel. See PushNotificationChannelManager.

The client code is similar for both the JavaScript backend and the .NET backend. By default, when you add push notifications for a JavaScript backend service, a sample call to notifyAllUsers custom API is inserted into the UploadChannel method.

C#

```
using System;
using System.Collections.Generic;

    }).then([](task<json::value> result)
    {
        try
        {
            result.wait();
        }
        catch(...)
        {
            HandleExceptionsComingFromTheServer();
        }
    });
}

void mymobileservice1234Push::HandleExceptionsComingFromTheServer()
{
}
```

JavaScript

```
(function () {
    "use strict";

    var app = WinJS.Application;
    var activation = Windows.ApplicationModel.Activation;

    app.addEventListener("activated", function (args) {
        if (args.detail.kind == activation.ActivationKind.launch) {

Windows.Networking.PushNotifications.PushNotificationChannelManager.createPu
shNotificationChannelForApplicationAsync()
                .then(function (channel) {

mymobileserviceclient1234Client.push.registerNative(channel.Uri, new
Array("tag1", "tag2"))
                    return
mymobileservice1234Client.push.registerNative(channel.uri);
                })
                .done(function (registration) {
                    return
mymobileservice1234Client.invokeApi("notifyAllUsers");
                }, function (error) {
                    // Error

                });
        }
    });
})();
```

Push notification tags provide a way to restrict notifications to a subset of clients. You can use the for the registerNative method (or RegisterNativeAsync) method to either register for all push notifications without specifying tags, or you can register with tags by providing the second argument, an array of tags. If you register with one or more tags, you only receive notifications that match those tags.

Server-side scripts (JavaScript backend only)

For mobile services that use the JavaScript backend, the server-side scripts run when delete, insert, read, or update operations occur. The scripts don't implement these operations, but they run when a call from the client to the Windows Mobile REST API triggers these events. The scripts then pass control onto the operations themselves by calling request.execute or request.respond to issue a response to the calling context. See Azure Mobile Services REST API Reference.

A variety of functions are available in the server-side script. See Register table operations in Azure Mobile Services. For a reference to all available functions, see Mobile Services server script reference.

The following custom API code in Notifyallusers.js is also created:

JavaScript

```
exports.post = function(request, response) {
    response.send(statusCodes.OK,{ message : 'Hello World!' })

    // The following call is for illustration purpose only
    // The call and function body should be moved to a script in your app
    // where you want to send a notification
    sendNotifications(request);
};

// The following code should be moved to appropriate script in your app
where notification is sent
function sendNotifications(request) {
    var payload = '<?xml version="1.0" encoding="utf-8"?><toast><visual>
<binding template="ToastText01">' +
        '<text id="1">Sample Toast</text></binding></visual></toast>';
    var push = request.service.push;
    push.wns.send(null,
        payload,
        'wns/toast', {
            success: function (pushResponse) {
                console.log("Sent push:", pushResponse);
            }
        });
}
```

The sendNotifications function sends a single notification as a toast notification. You can also use other types of push notifications.

Tip For information about how to get help while editing scripts, see Enabling IntelliSense for server-side JavaScript.

Push notification types

Windows supports notifications that aren't push notifications. For general information about notifications, see Choosing a notification delivery method.

Toast notifications are easy to use, and you can review an example in the Insert.js code on the channel's table that's generated for you. If you plan to use tile or badge notifications, you must create an XML template for the tile and badge, and you must specify the encoding of packaged information in the template. See Working with tiles, badges, and toast notifications.

Because Windows responds to push notifications, it can handle most of these notifications when the app isn't running. For example, a push notification could let a user know when a new mail message is available even when the local mail app isn't running. Windows handles a toast notification by displaying a message, such as the first line of a text message. Windows handles a tile or badge notification by updating an app's live tile to reflect the number of new mail messages. In this way, you can prompt users of your app to check it for new information. Your app can receive raw notifications when it's running, and you can use them to send data to your app. If your app isn't running, you can set up a background task to monitor push notifications.

You should use push notifications according to the guidelines for Windows apps, because those notifications use up a user's resources and can be distracting if overused. See Guidelines and checklist for push notifications.

If you're updating live tiles with push notifications, you should also follow the guidelines in Guidelines and checklist for tiles and badges.

Next steps

Using the Windows Push Notification Services (WNS)

You can call Windows Push Notification Services (WNS) directly if Mobile Services doesn't provide enough flexibility, if you want to write your server code in C# or Visual

Basic, or if you already have a cloud service and you want to send push notifications from it. By calling WNS directly, you can send push notifications from your own cloud service, such as a worker role that monitors data from a database or another web service. Your cloud service must authenticate with WNS to send push notifications to your apps. See How to authenticate with the Windows Push Notification Service (JavaScript) or (C#/C++/VB).

You can also send push notifications by running a scheduled task in your mobile service. See Schedule recurring jobs in Mobile Services.

Warning Once you've run the push notification wizard once, don't run the wizard a second time to add registration code for another mobile service. Running the wizard more than once per project generates code that results in overlapping calls to the **CreatePushNotificationChannelForApplicationAsync** method, which leads to a runtime exception. If you want to register for push notifications for more than one mobile service, run the wizard once and then rewrite the registration code to ensure that calls to **CreatePushNotificationChannelForApplicationAsync** do not run at the same time. For example, you can accomplish this by moving the wizard-generated code in push.register.* (including the call to **CreatePushNotificationChannelForApplicationAsync**) outside of the OnLaunched event, but the specifics of this will depend on your app's architecture.

How to request, create, and save a notification channel

Article • 10/25/2021

You can open a channel Uniform Resource Identifier (URI) over which your app can receive push notifications. You can then send the channel to your server which uses it to send push notifications, and close it when you no longer need it. A channel is a unique address that represents a single user on a single device, for a specific app or secondary tile.

You should request a new channel each time that your app is launched, and update the cloud server when the URI changes. For more details, see Remarks.

> **Important**
>
> Notification channels automatically expire after 30 days.

What you need to know

Technologies

- Windows Runtime

Prerequisites

- Familiarity with push notification and Windows Push Notification Services (WNS) concepts, requirements, and operation. These are discussed in the Windows Push Notification Services (WNS) overview.

Instructions

Step 1: Add namespace declarations

Windows.UI.Notifications includes the toast APIs.

```
C#
```

```
using Windows.UI.Notifications;
using Windows.Data.Xml.Dom;
using Windows.Networking.PushNotifications;
```

Step 2: Request a channel URI

This example requests a channel URI. The request is made to the Notification Client Platform, which in turn requests the channel URI from WNS. When the request is complete, the returned value is a PushNotificationChannel object that contains the URI.

C#

```
PushNotificationChannel channel = null;

try
{
    channel = await
PushNotificationChannelManager.CreatePushNotificationChannelForApplicationAs
ync();
}

catch (Exception ex)
{
    // Could not create a channel.
}
```

Step 3: Send the channel URI to your server

The channel URI is packaged in an HTTP POST request and sent to the server.

> **ⓘ Important**
>
> You should send this information to your server in a secure manner. You should require the app to authenticate itself with the server when it transmits the channel URI. Encrypt the information and use a secure protocol such as HTTPS.

C#

```
String serverUrl = "http://www.contoso.com";

// Create the web request.
HttpWebRequest webRequest =
(HttpWebRequest)HttpWebRequest.Create(serverUrl);
webRequest.Method = "POST";
```

```
webRequest.ContentType = "application/x-www-form-urlencoded";
